*ANSWER*—The majority of investigators today favor 'the mechanical theory of epilepsy', that is, the theory that the immediate, precipitating cause of the convulsion is cerebral edema. This edema is the result of a disturbance in water balance whereby the brain cells become abnormally swollen with excess fluid or else the spinal fluid reservoirs accumulate excessively large amounts of fluid or both. Theoretically and experimentally it may be demonstrated that rigid fluid restriction will dehydrate the body tissues, including finally the brain. Fay introduced fluid restriction or dehydration in the treatment of epilepsy and suggested that the beneficial effect of the ketogenic diet was at least partly due to its dehydrating action. Hydration by forcing fluids or by injecting a fraction of pituitary extract or both will often precipitate a convulsion in an epileptic patient, while rigid fluid restriction, including foods with high water content, will control grand mal attacks. It seems to have no effect on petit mal seizures. Restriction to less than 400 cc (13 ounces) may cause erythrocyturia and must be carefully watched. Details of the diet preparation and fluid regulation is well as references to the literature may be found in the *Annals of Surgery* 101:76 (Jan) 1935.

#### DYSMENORRHEA

*To the Editor*—My problem is one of dysmenorrhea but is different from what I have seen in literature in that the severe pain comes on one or two hours after the patient starts flowing. She is 23 years old has been married one and a half years, and has had no pregnancy to date. She started menstruating at 15, of the regular twenty-eight day type. Dysmenorrhea has occurred ever since becoming worse since she married. The patient is sick three days before flowing starts with nausea, belching of gas, dizziness and weakness. During this time she has severe pain in the right lower part of the abdomen over the right ovary. She is in bed usually four days. Physical examination gives normal results except for a slightly retroflexed uterus smaller than normal. Would you suggest dilation and curettage in this case? Any suggestions would be appreciated. Please omit name if published.

M D, Minnesota

*ANSWER*—This is evidently a case of congenital primary or essential dysmenorrhea, in which there is freedom from demonstrable pelvic abnormality. The causes of this kind of dysmenorrhea have not as yet been satisfactorily explained. It is agreed that cramping of the uterine musculature is responsible for the pain. Beyond this point one passes into the realm of theories.

Dilation brings permanent relief to a small percentage of the patients. Curettage is apparently of little value.

Based on the theory that an excess of estrogenic substance is responsible for the painful contractions the interior pituitary-like gonadotropic principle of pregnancy urine has been employed for its inhibiting influence. The value of this therapy remains to be determined.

Abdominal exploration in search for hidden lesions together with resection of the presacral nerve is advocated for the most serious cases. Many conservative gynecologists are impressed with the relief afforded by resection of the presacral nerve.

For patients in whom operative intervention appears to be too extreme a measure, codeine may be given in generous doses without fear of creating a habit, morphine should be avoided.

#### INTRAVENOUS ADMINISTRATION OF SOLUTIONS

To the Editor—There are several questions regarding the intravenous administration of various solutions which have evoked considerable differences of opinion. Would you be kind enough to elucidate them for me? 1 What is the optimal rate of flow for administration of dextrose saline solution and arspenamine intravenously? 2 Should the rate of flow vary with the concentration of the solution? 3 At what temperature should the solution enter the vein? 4 To what temperature should the fluid in the containing vessel be heated in order to obtain the desired temperature at the needle point? 5 How should the solution be heated?

LOUIS R. FERRARO, M.D., Bronx, N. Y.

ANSWER—1 Literally drop by drop administration of intravenously injected fluid, or 60 drops per minute is the optimal rate for the introduction of fluid in great bulk.

2 The more toxic or unphysiologic the fluid, the slower should be its rate of injection.

3 With the intravenous drip, the temperature of the fluid entering the vein need not be above the temperature of the room, though, of course, blood temperature (100 F) is optimal.

4 It has been estimated that one may figure on the loss of one degree of temperature per foot of rubber tubing though this is, of course, a mere rough approximation. A sterilizable thermometer-containing glass tube inserted in the rubber tubing near the patient is the most efficient way of observing the temperature of the fluid as it is delivered to the patient.

5 For keeping the solution warm, all sorts of devices have been proposed, from vacuum bottle containers and the partial immersion of a sterilized electric light bulb into the fluid to the use of a heating pad (preferably electric) surrounding the flask or the tubing in its course.

#### TREATMENT OF DIABETES

To the Editor—A white woman aged 58 has had diabetes mellitus about fifteen years. On a restricted diet she can hold her weight and strength and feels well but with this diet it is not possible consistently to keep her sugar free. I also have a patient of 83 with a similar condition. Neither patient takes well to the idea of insulin. Is it possible for elderly diabetic patients to show a little sugar and still be reasonably safe from the danger of coma? Please omit name. M.D. Alabama

ANSWER—It is reasonably safe for patients 58 and 83 years of age to show slight glycosuria and yet avoid coma. On the other hand experience proves that, unless these patients are really under supervision and sugar free a considerable part of the time, they are liable with sudden changes of diet or an infection to develop severe glycosuria and acidosis. The hope for making progress in treating diabetes is to protect and treat thoroughly the mild and the moderately severe cases rather than to neglect them by concentrating on the very severe cases. It is something like the care of wounds on the battle field. The same amount of time and attention necessary to care for a severely wounded soldier with scant outlook for life, if expended on ten slightly or moderately wounded may save ten times as many. Fortunately in peace all diabetic patients can receive attention.

Determinations of blood sugar as well as determinations of the total amount of sugar excreted in the urine in twenty-four hours are most helpful as guides to treatment as regards both diet and insulin.

#### THROMBOANGITIS OBLITERANS

To the Editor—A patient with thromboangitis obliterans does not have diabetes and has gained wonderfully. He has had the trouble for about four months but sleeps and eats well. He refuses an operation. Kindly tell me what theobromine or theophylline preparation I should get to dilate the coronary arteries. M.D. Kansas

ANSWER—Many patients who have thromboangitis obliterans or arteriosclerosis obliterans need no active treatment, as the collateral circulation frequently develops to a point at which the circulatory needs are satisfied. If the arteries of the feet or hands are closely rigid protective measures should be instituted. Great care in trimming the nails, prophylactic measures to prevent trichophytosis and modified measures to treat it, avoidance of applying irritating antiseptic solutions to the skin, preservation of heat in the feet or hands during cold weather, and fre-

quent changing of shoes and hose are simple measures which, if rigorously carried out, frequently prevent trophic ulcers. Interdiction of tobacco is important. Reduction in exercise with lessened wear and tear on the feet should be advised. If an ulcer is present, enforced rest to the affected extremity, frequent soaking in warm physiologic solution of sodium chloride, postural exercise and protein fever therapy are helpful if healing is slow or if there is pain. Sympathetic ganglionectomy may be advisable for protection from future ulcers or gangrene.

Theobromine in doses of 0.3 Gm (5 grains) three or four times a day with equal amounts of soda theophylline ethylenediamine in doses of from 0.2 to 0.3 Gm (3 to 5 grains) and theophylline in doses of from 0.1 to 0.2 Gm (1½ to 3 grains) three times a day, when administered continuously for a long period, seem to have a beneficial effect on the coronary circulation. The use of the newer tissue extracts likewise seems to relieve the symptoms in coronary disease probably not by dilating the coronary vessels but by some metabolic effect on the heart muscle.

#### SPONDYLOLISTHESIS WITH LOW BACK PAIN

To the Editor—A man aged 59 has a marked spondylolisthesis. The articular facets between the fourth and fifth lumbar vertebrae show osteoarthritic changes. The tonsils were removed thirty years ago. The teeth are normal. The gallbladder and the genito-urinary tract are negative. He states that the left ear has discharged intermittently for the last twenty years. The drum is perforated and slight moisture surrounds it. Would the intermittently discharging ear be a focal cause for the osteoarthritis? Kindly omit name. M.D. New York

ANSWER—The osteoarthritic changes in the articular facets between the fourth and fifth lumbar vertebrae might possibly be accommodative structural changes to reinforce these joints in their abnormal relations.

It is more probable, however, that they are true osteoarthritic changes due to focal infection and appearing at a point of unusual stress and shearing strain. It seems likely that the middle ear disease might be a sufficiently active focus to be the cause.

If the low-back symptoms are severe enough to warrant operation, complete relief could probably be attained by fusing the fourth and fifth lumbar vertebrae to the sacrum. This is usually best done by a combination of the Albee and the Hibbs methods. The first recorded operation for spondylolisthesis was performed by the Albee bone-graft method in 1914, as reported by Edwin W. Rycerson (THE JOURNAL, Jan 2, 1915). This patient was seen twenty years later and had had no recurrence of symptoms. Many other successful results have since been reported. The operation itself is not dangerous, even in elderly people.

#### SENSITIVITY TO ARSPHENAMINE

To the Editor—A man aged 35 first came for treatment one year ago with evidences of secondary syphilis. The blood Wassermann reaction was positive. He was given eight intravenous neoarsphenamine (0.6 Gm) treatments. He developed immediately after this a severe exfoliating dermatitis. He was then put on quinine bismuth iodide 2 cc intramuscularly each week. This was continued for two months the skin condition gradually clearing. Then another dose of neoarsphenamine (0.45 Gm) was given. Diarrhea and a severe dermatitis immediately followed and the dermatitis took six months to be relieved. Since then he has stayed on the bismuth preparation intramuscularly each week and occasional series of mercury with chalk 1 grain (0.06 Gm) after meals. The Wassermann reaction at the end of a year is still positive. I am reluctant to give any neoarsphenamine to this patient. There is a new preparation of arsenic which is claimed to be less poisonous than neoarsphenamine. This is called Metpharsen Parke Davis & Co. Would this preparation be safe to try on this very sensitive patient? He is symptom free but the blood Wassermann reaction is positive after the year's treatment. What treatment would be best in your opinion in such a case? Please omit name. M.D. Massachusetts

ANSWER—In a patient who has such a marked hypersensitivity to the arsphenamines, it is not advisable to attempt any further medication with any arsenical preparations. Treatment should be confined to intramuscular bismuth preparations alternating with iodides and mercury. A severe exfoliative dermatitis is much more dangerous than a positive Wassermann reaction.

#### ARGYRIA

To the Editor—What is the danger of argyria following lavage of the kidney pelvis and bladder or both with silver nitrate or any other silver salt? One case has been reported to me but it has not appeared in the literature. My opinion is that the danger is negligible. Will you kindly enlighten me? Please omit name. M.D. Utah

ANSWER—When the correct strength of silver nitrate solution is used in the urinary tract the danger of argyria is remote.

### New York September Examination

Mr Herbert J Hamilton, chief, Professional Examinations Bureau, reports the written examination held by the New York State Board of Medical Examiners in Albany, Buffalo New York and Syracuse, Sept 16-19 1935. The examination covered 9 subjects. An average of 75 per cent was required to pass. Two hundred and twenty-two candidates were examined, 163 of whom passed and 59 failed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
University of Arkansas School of Medicine	(1932)		1

## Book Notices

Health and Human Progress. An Essay in Sociological Medicine. By  
 René Sand. Lecturer at the University of Brussels. Preface by Edouard  
 Herriot. Cloth. Price \$3. Pp 278. New York: Macmillan Company,  
 1936.

The author of this volume is enamored of the term sociologi-  
 cal, which is indeed a fine round word to roll on the tongue.  
 In his opening chapter he delivers himself of a grandiose,  
 utopian conception of sociological medicine which includes socio-  
 logical obstetrics, sociological pediatrics, sociological psychiatry,  
 sociological dermatology, urology and gynecology, not to over-  
 look phthisiology, neurology, epidemiology, cardiology and  
 stomatology. "Each branch of medicine has its sociological  
 aspect." Precisely so, but not set off by itself in a glorified  
 sociological pigeonhole. Each branch of medicine has always  
 had its sociological aspect, and the great physicians of all time  
 have been those who have been social philosophers and leaders  
 in the great sociological reforms which M Sand eulogizes as  
 if the physician had little or nothing to do with them, except  
 perhaps with their imperfections, as in his contemptuous dis-  
 missal of errors in reporting of causes of death "due to family  
 prejudices or negligence and indifference on the part of the  
 doctors." The author admires "the profound researches and  
 carefully weighed conclusions of the Commission [sic] on the  
 cost of medical service in the United States" without apparently  
 realizing the fundamental differences between the majority and  
 the minority reports. Chapters are devoted to the social  
 classes, "their physical and mental inequality, and their inequality  
 in respect to sickness and death. The influence of health on  
 human progress is discussed from the standpoint of heredity,  
 environment, occupation, domestic factors, economic factors,  
 sanitary and educational factors and human economics. There  
 is an extensive sociological bibliography and an index. An  
 introduction by M Edouard Herriot summarizes M Sand's  
 program as one to make progress serve us instead of enslave  
 us." The author's program is a broad collectivism which will  
 extend into all phases not only of health but of all human  
 progress. With his underlying objective the conservation of  
 human capital and the broadening of human life by better wages  
 and more consideration in commerce and industry for the human  
 being, no reasonable person would take issue. There remain  
 many, however, who will not be willing to sacrifice their indi-  
 vidual independence and initiative, which may indeed bring them  
 suffering today, but always with an opportunity for glory  
 tomorrow, for regimented health movements, regimented educa-  
 tion, regimented thinking, regimented lives even with garden  
 cities, maternity canteens, day nurseries, soviet-dietetic meals  
 and civic and social centers where all will have free and equal  
 servings from the milk and honey of the promised land. Regi-  
 mentation is not as happy a word as sociological, but apparently  
 it means about the same.

*Traité de chirurgie d'urgence* Par Félix Lejars. Refondu par Pierre Brocq, professeur agrégé à la Faculté de médecine de Paris avec la collaboration de Robert Chabrut. In two volumes. Ninth edition. Cloth. Price 200 francs per set. Pp 686 689 1299 with 1 250 illustrations. Paris: Masson & Cie 1936.

It will be a great gratification to all surgeons and students to learn that despite Lejars' lamentable death in 1932 his splendid *Chirurgie d'urgence* did not perish with him. Since the eighth edition published in 1921, Lejars had contemplated the preparation of a new one. Fatigue and illness prevented this cherished desire and when he recognized its impossibility he entrusted the task to his colleague Pierre Brocq and to Robert Chabrut, who have produced a splendid revision. The realistic stimulating and even dramatic descriptions of Lejars have not been sacrificed. The first personal pronoun is no longer present but the spirit of the old master is felt on every page. The illustrative cases are still present. Much new material has been added to bring the work down to date. Most of the illustrations have been entirely redrawn and many new ones have been added including pertinent roentgenograms. Obsolete material has been omitted. Urgent surgery is not to be confused with minor surgery. The many grave conditions of the different regions of the body due to accident or disease, which require prompt attention are carefully considered from the standpoint of diagnosis and treatment. At times the authors find it difficult to stay within the confines prescribed by the title, but these deviations enhance rather than detract from the work. While in some few matters American opinion might differ with the French, in the main the book is well written, well illustrated, and based on a wealth of experience. It is recommended with confidence.

*Behavior Development in Infants. A Survey of the Literature on Prenatal and Postnatal Activity 1920-1934.* By Evelyn Dewey. Published for the Josiah Macy Jr. Foundation. Cloth. Price \$3.50. Pp 321. New York: Columbia University Press 1935.

Behavior is defined for the purpose of this summary as "the neuromuscular and glandular reactions of living human organisms." Unfortunately the social and emotional development has not been included because "there is as yet no satisfactory theory of the process underlying strictly objective neuromuscular behavior patterns." But not all human responses emerge from drives, gestalt or mental factors. The purpose of the survey was to select salient results for correlation with the research program of the Child Development Clinic at the Neurologic Institute. Studies of child development are essentially descriptive in terms of age levels. This summary is of necessity under the group headings of fetal, neonatal and infant behavior.

The progressive development of the various growth patterns is evaluated from conception. Evidence abounds that the reactions of premature infants are not different from infants born at term. But behaviorists credit the environment with initiating behavior. Their contention is that most postnatal responses are learned with the exception of a few labeled "unconditioned." The gestaltists contend that behavior patterns are present at birth and that specific behavior develops from a fundamental relation, oriented within the organisms, to the external world. It is known however that some types of behavior have been completely developed in utero, other types have begun to develop and have reached different levels of growth at birth, and still others are not developed until after birth. Extreme versions of behaviorists suffer because they explain too much. They suggest that the child is fabricated out of conditioning patterns. They do not give due recognition to the internal regulatory mechanisms which delimit conditioning and which happily prevent grotesque consequences and which the theories themselves would make too easily possible. On the other hand, the rigid views of gestaltists exclude environmentalism as markedly affecting developmental patterns. Although it is artificial to present a distinction between intrinsic and extrinsic factors it must be granted that growth is a function of the organism rather than of the environment as such. Maturation suggests stabilizing factors that safeguard the basic patterns of growth. Demonstration of determining factors is inconclusive. Few studies have thus far been made tracing the development of any one behavior pattern from earliest reactions to the fully developed ones of the mature being.

No sharp developmental break exists in the transition from fetal to neonatal and from that to infant life. There is, however, a period of latency which corresponds to the accepted principles in the development of neural structures. It is not yet possible to determine whether all types of behavior are controlled during all their different growth stages by the same mechanism. The early stepping movements for example, might then be linked to the period of walking by the latent transition from the cortical to the subcortical progression only when the organism is physiologically ready to effect purposive walking. Development of any one pattern appears to be progressive and gradual with probably latent periods if not actual regression, during which some other pattern is developing at an accelerated rate. Development of one pattern does not proceed to the exclusion of others but all are progressing simultaneously at different rates with vastly different ages for maturity and with different periods of accelerated growth.

The complex of varied growth during infancy becomes even more difficult of interpretation. Patterns have not been traced from the reaction occurring at birth to the fully developed form. The method of tracing the emergence of differentiated reactions from total behavior is just beginning to be applied. Unfortunately, most of the literature is still concerned with a single stage in the development of any one pattern, the appearance of a specific type of reaction rather than with the progressive stage leading up to and including the particular skill. Behavior development for the individual means adequate adjustment to the environment for the support of life independently. Yet the course of development has not been particularly investigated from this purposive basis.

The literature on infant behavior has been assimilated and interpreted lucidly. Nevertheless it is impossible to present an adequate picture of the total growth pattern or of the fundamental processes underlying it. The difficulties to be overcome are clearly indicated by the author. The evidence available supports no one of the current theories of behavior. The author veers toward the gestalt school with particular emphasis on the role of maturation of the nervous system.

*Lehrbuch der inneren Medizin* Von Professor Dr. Theodor Bruch, o. Professor der Medizin an der Martin Luther Universität Halle-Wittenberg. In two volumes. Third edition. Paper. Price 50 marks 55 marks. Pp 796 with 177 illustrations. 797 1628 with 218 illustrations. Berlin & Vienna: Urban & Schwarzenberg 1936.

In the preface to this edition of his textbook on internal medicine the author states that he eliminated all superfluous material to make the book more compact, and yet the two volumes contain 1,628 pages. Many changes have been made especially in the chapters on neurologic diseases and intestinal disorders, and the entire text has been brought down to date. Space allotted each disease was justly selected according to the practical importance of the subject. The statement that there is no pure race in Europe is apparently not in harmony with the opinion of the government of the country where this work has been published. Each chapter begins with a brief description of the normal and pathologic anatomy and physiology of the organ discussed. Numerous reproductions of photographs, roentgenograms and also colored charts supplement the text. The growing tendency in this country to provide an adequate amount of carbohydrates and to decrease the fat intake by diabetic patients is apparently not shared by the author. Several omissions have been noticed, e.g. relative avitaminoses, the use of viofilm and carbarsone in amebic dysentery, the Kahn test in syphilis, the value of phonocardiography in heart diseases and of bronchoscopy in lung cancer, the use of mucin in gastric ulcers, decompression with the indwelling catheter and the merits of intravenous injections of hypertonic saline solutions in intestinal obstruction and various methods of production of artificial heat superseding inoculation with malaria. Recommendation of proprietary drugs detracts greatly from the usefulness of the book for foreign readers. The immense wealth of material makes the work encyclopedic in character, so that it can be considered rather as a reference book than as a text book. Undoubtedly it is one of the most important works on this subject published in recent years in the German literature. It offers an excellent picture of the latest conceptions of continental internists on many problems of internal medicine.

**La pratique stomatologique** Publiée sous la direction du Dr Chompret  
III Technique chirurgicale bucco-dentaire Par les Drs Chompret  
Dechaume et Richard Clohir Price 15 francs Pp 283 with 174 illustrations Paris Masson & Cie 1935

This volume is the third of a nine volume set and deals with the surgical technique of the oral cavity. The other volumes are I Pathology of Mouth and Surrounding Tissue II Dental Pathology IV Operative Dentistry V Removable Prostheses VI Crowns and Bridges VII Orthodontia VIII Restorations and Prostheses of Maxilla and Face IX Radiography. Each volume is written by various men who are engaged in the practice of the various specialties enumerated and the illustrations and texts form a summary of their years of experience. The system is intended for both students and practitioners. The first part of this volume is given to the anatomy of the various regions of the head and neck. The second part is devoted to the operating room, including preparation of surgical material, sterilization, and preoperative and postoperative treatment. The third part is devoted to anesthesia general, local and regional. The fourth deals with extraction of teeth and roots, with instrumentation applicable to each. The extraction of children's teeth is considered especially. The fifth part outlines the extraction of unerupted teeth, curettage and amputation of tooth roots including most operations done by the oral surgeon, including fractures and tumors. The sixth part includes surgery of the soft parts. The last part considers surgery of congenital and acquired disorders. The book is profusely illustrated by drawings showing the anatomic relations of various tissues, together with instruments and the technique of their uses.

**Tumors of the Urinary Bladder** By Edwin Beer MD FACS Visiting Surgeon Mount Sinai Hospital New York City Cloth Price \$3.50 Pp 166 with 52 illustrations Baltimore William Wood & Company 1935

This monograph is based on an exhaustive study of tumors of the urinary bladder carried on over a period of twenty-three years. It is divided into twelve chapters and begins with a historical sketch as a foundation. The chapter on pathology is particularly interesting and instructive. Here the author has been assisted by members of his staff, and their personal experiences add much to its value. The chapters on treatment include a discussion of the various methods of approach and give a clear description of operative technique with excellent illustrations. In these chapters one obtains good statistical data and here the author shows an open mind and gives the reader the benefit of his conclusions based on a wide experience. The book contains an excellent bibliography. This work is a valuable addition to urologic literature and is recommended to the urologist, pathologist and general practitioner.

**Common Skin Diseases** By A. C. Roxburgh MA MD BCh Physician in charge of the Skin Department and Lecturer on Diseases of the Skin St Bartholomew's Hospital General Practice Series Third edition Cloth Price 15s Pp 377 with 148 illustrations London H. K. Lewis & Co Ltd 1936

Roxburgh has prepared a third edition of his book in view of the exhaustion of the second edition within sixteen months of its issue. He has added a brief article on gold dermatitis, Besnier's prurigo, recurrent cellulitis and diet in lupus vulgaris. Eleven illustrations have been added, and these together with the colored plates are excellent supplements to the succinct descriptions in the text. The book deals only with the common skin diseases. Stress is laid on differential diagnosis and the chapter on the index of preliminary diagnosis for students is worthy of special mention. For a readable well illustrated small textbook of common skin diseases it has many features to recommend it as a useful book for students.

**The Osteopathic Lesion** By George Macdonald MB ChB DO and W. Hargrave Wilson DO Cloth Price 7s 6d Pp 141 with 5 illustrations London William Heinemann Ltd 1937

This was intended by the authors, one of whom is both a Bachelor of Medicine and a Doctor of Osteopathy as a defense of the practice of osteopathy. Even after reading it one cannot obtain an entirely clear understanding of just what the authors mean by the "osteopathic lesion." The authors emphasize that osteopathy is not a process of manipulation or a procedure that

is useful in every condition of ill health. They briefly discuss the anatomy of the spine, the physiologic considerations which they consider to be of osteopathic importance, the osteopathic lesion itself, which they consider to be a result of trauma initiating the somatovisceral reflex, and the effects of repeated trauma, usually on a spinal joint with associated changes in ligaments and soft tissue structure. The effect of the lesion may be localized, peripheral, visceral or general. In the final chapter an attempt is made to describe the osteopathic treatment which is supposed to relieve not only the primary condition but also the secondary phenomena. The reasoning is highly theoretical. Even attempting an attitude of fairness, there does not appear to be any justification for this book. The result of reading it has simply added conviction that osteopathy accomplishes its results largely by the psychic effect on the patient, who is impressed by the fact that something is being done.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Hospitals Liability to Visitor for Injury Due to Fall on Polished Floor**—The plaintiff, while visiting the defendant hospital, slipped on the waxed linoleum covered floor of the hallway of the hospital and fractured her arm. She sued the hospital, and when the trial court directed a verdict against her, she appealed to the Supreme Court of Mississippi, Division B.

The owner or person in control of a building, said the Supreme Court, such as a hospital, must exercise reasonable care to construct and maintain the floors in the building so that they will be reasonably safe for those who have the right to use them. If, as in the present case the danger complained of is one that is entirely open and visible, the doctrine of *res ipsa loquitur* does not apply. The proprietor is not an insurer but is liable only for negligence. An owner or proprietor charged with negligence as to an appliance, way or method is not liable when he complies with the customary, generally recognized standards employed by careful and prudent men in the same business or occupation. In the present case the evidence showed that the type of linoleum on the floor had been for a long time in common and general use, under substantially the same method of maintenance, in stores, office buildings and other buildings where members of the public are invited to visit and do visit. The evidence further showed that the linoleum had been regularly cleaned and waxed, according to the directions of the manufacturer, and that this was the first injury that had occurred from its use. The court could see no reason for applying a rule of liability to hospitals different from the rule applicable to other buildings visited by the public and consequently affirmed the verdict for the hospital.—*Daniel v. Jackson Infirmary (Miss)*, 163 So 447.

**Embalmers Inherent Right of Board to Revoke a License, Causes for Revocation Must be Specifically Stated**—The plaintiff, a licensed embalmer, employed an unlicensed person to embalm a body for him. The Oklahoma state board of embalmers notified the plaintiff that he had thereby violated the board's rules and regulations and that on a certain date the board would determine if his license should be revoked. The plaintiff sought to restrain the board from proceeding against him but the trial court denied the relief sought and the plaintiff appealed to the Supreme Court of Oklahoma. He contended among other things, that the embalming act conferred on the board no authority to revoke a license and that therefore the board was without jurisdiction to proceed against him.

The embalming act said the Supreme Court does not expressly provide for the revocation of licenses. It does confer on the board authority to adopt rules and regulations whereby the performance of the duties of said board and the practice of embalming dead bodies, and the conduct of schools for teach-

ing embalming, shall be regulated" The plaintiff contended that the power given by the act to the board to promulgate rules and regulations did not authorize the board to cancel his license or to adopt rules for such purpose. There is considerable authority, the court said, supporting the plaintiff's contention and it finds reinforcement in the fact that in analogous acts the legislature has generally expressly granted the power of revocation of licenses and prescribed the grounds and manner of revocation, as in the case of accountants, barbers, dentists, architects, graduate nurses physicians and others. But even assuming, the court said, without deciding, that the conferment on the board of power to make rules authorized it to provide for the revocation of licenses, the board adopted no rule expressly prohibiting a licensed embalmer from employing an unlicensed assistant to embalm bodies under his order and direction. Any rules adopted by the board providing for the revocation of licenses must specify the acts constituting the basis or cause of revocation with such reasonable clarity and particularity as to enable a licensee to determine in advance of his acts whether or not they will violate the rules and be capable of becoming the basis of a proceeding for the revocation of his license. So far as the rules of the board in the present case fail in this respect, the court said, they are void. The board is not authorized to proceed under a rule setting forth a general and indefinite power of revocation.

The court held, therefore, that the board in instituting proceedings to revoke the plaintiff's license acted outside the scope of its jurisdiction and attempted to exercise unauthorized judicial powers. The judgment of the trial court was reversed with direction to grant the plaintiff the relief sought.—*Moore v. Vincent (Olla)* 50 P (2d) 388

**Workmen's Compensation Acts** **Compensability of Neurosis**—Under the Arizona workmen's compensation act says the Supreme Court of Arizona, for a worker to obtain compensation for a neurosis following an industrial accident it must be shown that that neurosis was the result of some injury sustained in the accident.

In this case the worker while employed in sulfide ore mines had to run four or five hundred feet to reach fresh air when the mine shaft in which he was working accidentally became filled with smoke, sulfur gas and dust. The exertion and the inhalation of those substances caused him to choke, cough, vomit and lose his breath. He suffered temporary pulmonary disorders and inflammation of the respiratory organs and of his eyes. Subsequently he developed a neurotic condition, which the industrial commission in granting him compensation under the workmen's compensation act, found was traceable in part to circumstances arising out of and immediately following his alleged injury. The employer appealed to the Supreme Court of Arizona.

The workmen's compensation act of Arizona said the Supreme Court clearly contemplates that an injury to an employee by accident is compensable whatever that injury may be. Mental or physical suffering which does not lessen the employee's ability to work and earn wages is not compensable the theory of the law being to remunerate or compensate the employee to the extent of disablement by reason of his injury. The injury may be a disease and a neurosis is a disease. To entitle an employee to compensation for disability from a disease, however the disease must result from or be produced or aggravated by an injury. If the commission had found that the employee's neurosis was caused by an injury sustained in an accident then the award of compensation would have been proper. While the commission in its findings did not so state, the court said the only conclusion to be drawn from the findings is that the commission believed the employee's neurosis was not induced by any personal injury he suffered, but by a fear or apprehension of imaginary ailments that might follow as a result of his injury and the deplorable condition in which his family might be left. There was medical testimony to sustain such a conclusion. There being no finding that the employee's neurosis was the result of an injury, the award was set aside.—*Phelps Dodge Corporation v. Industrial Commission (Ariz)* 49 P (2d) 391

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Neoplasms in Cryptorchids**—Owing to the obscure nature of tumors of undescended testicles, an early diagnosis has been difficult. With the use of the quantitative follicle stimulating factor test it seems unquestionable that they can be recognized in an early stage, long before marked clinical symptoms have developed. Christoffersen and Owen would suggest that this test be used in all cases presenting suggestive histories. It is not so much, however, the positive observation which is important as it is the steady increase in output of gonadotropic substance in these cases when they are untreated. Some of the teratomas of the mixed adult type may be extremely resistant to irradiation. Accurate histologic classification should therefore be attempted for it is well known that the seminoma group is relatively radiosensitive. A decrease in the follicle stimulating factor following irradiation indicates sensitivity to irradiation, although some cases which should be radiosensitive histologically still show a high gonadotropic substance test. Such cases always have a grave prognosis. In

following these patients after discharge it is possible to utilize for purposes of assay specimens sent by mail. Mailing tubes equipped with 3-ounce bottles each containing one drop of trieresol as a preservative, are supplied to the discharged patients at regular intervals. In this manner at least one type of cheek can be obtained on the distant patient. Five case reports are given, showing the typical observations.

**Enzyme Content of Adenocarcinoma of Pancreas**—Sugiura and his co-workers obtained a large amount of pancreatic tumor from a specimen removed at operation. The tumor was a large solid parenchymatous adenocarcinoma occupying the tail and much of the body of the pancreas. Despite its large size it was not necrotic and no metastases were found. This pancreatic tumor was studied from the physiologic point of view and its enzyme content was compared with that of three normal human pancreases. The amylolytic action on starch, the proteolytic action on casein and pectone and the lipolytic action on seven esters of the four specimens was determined. Under comparable conditions the rate of digestion of starch, the degree of protein hydrolysis and the degree of hydrolysis of esters by the extracts of the pancreatic tumor were essentially the same as for normal pancreas. The 'pictures' of the relative ester-hydrolyzing actions of the two tissues were similar. The studies suggest that this tumor had a physiologic as well as a morphologic resemblance to normal human pancreas.

Hair Plucking A Blevier St Louis—p 336

**Changes in Type of Landry's Paralysis**—Tanaka observed that the clinical symptoms and course of Landry's paralysis (fourteen cases) in the Yamaguchi district have gradually changed during the last four years. Cases of the typical form, with peripheral paralysis of the spinal nerves were seen first. The paralysis was severe and recovery was not obtained for many months. Next appeared a type characterized by severe spontaneous pain in the joints muscles and skin of the paralyzed portion of the body on passive and active movement and on pressure. However, the intensity of the paralysis and of the atrophy of the muscles was not severe, and recovery was obtained more quickly than in the earlier cases. The most recent type has been characterized by severe paralysis of the cranial nerves but the pain has been less intense and recovery from the paralysis has been more prompt. In short the type of disorder noted during the four years has progressed gradually from involvement of the peripheral nerves to that of the central nervous system.

**Absorption of Carotene**—Heymann shows that the degree to which carotene is metabolized cannot be considered constant even in one and the same healthy child. Infections greatly diminish the intestinal absorption of carotene. Children with chronic infections should therefore be given foods rich in carotene or carotene solution in oil in amounts larger than those usually prescribed. Clausen recommended that preference be given to vitamin A which seems to be more easily absorbed. The diminished absorption of carotene during infections is not caused by fever as such but is more likely due to some until now unknown toxic factor. The fact that from ten to fourteen days after the last day on which fever was present a marked decrease in the absorption of carotene may still be present

shows that intestinal function may still be disturbed and therefore justifies again an old pediatric rule, namely, that special care should be taken in the feeding of infants even for two weeks after an infection has subsided. The fact that infections in infants who were not suffering from diarrhea were found to interfere with intestinal function (digestion of fat, absorption of carotene) may throw light on the still unsolved problem of the etiology of the so-called parenteral dyspepsias.

**Recurrence of Pneumonia in Childhood**—During a period of eleven years there occurred at Greene's institution 561 cases of pneumonia. Eighty children suffered 202 attacks of pneumonia. In 50 per cent of the children who had more than one attack of pneumonia the initial attack occurred during the first year of age, in contrast to 38 per cent of the group of patients having a single (primary) attack of pneumonia. The sexes were about equally divided. There were fifty-two children who had two attacks, eighteen who had three, seven who had four, two who had five and one who had six. In the present study of the recurrent attacks of the disease there were 138 cases of lobar pneumonia and sixty cases of bronchopneumonia. In the cases analyzed, it is found that in 67 per cent of the recurrences the character of the lesion was of the same nature as in the first attack. In thirty-three of the cases of recurrent pneumonia the lesion occurred on the same side and in thirty-four on the side opposite that involved in the first attack. There are exceptional instances. Analysis of the non-fatal cases showed the illness to have terminated in from three to five days in twenty-nine, in from six to ten days in forty-nine, in from eleven to fifteen days in twenty-six and in sixteen days or more in six. The recurrence was of the same duration as the initial attack in 26 per cent of the cases. In 31 per cent the recurrence was longer and in 43 per cent it was shorter than the primary attack. The mode of termination in the recurrent attack was similar to that of the primary attack, regardless of type, in 63 per cent of the cases. There were seven deaths from lobar pneumonia or bronchopneumonia in the recurrent cases, giving a mortality rate of 35 per cent as compared with a rate of 167 per cent in the group of primary cases of pneumonia of both types. In each fatal case of recurrent pneumonia there was some important contributing factor, or the preceding attack was unusually severe. The low death rate is remarkable, particularly as half the patients were less than 1 year of age at the time of the first attack. Although allowance must be made for the small number of cases dealt with in the fourth, fifth and sixth attacks, the tendency is for the mortality rate to become less and less with each subsequent attack. In other words, the patients with recurrent pneumonia are probably a select group since they are able to withstand repeated attacks of pneumonia either because of natural resistance or because of some acquired immunity.

**Treatment of Acute Empyema Thoracis**—Bettman has used a form of treatment for acute empyema for which he uses a Pezzar catheter and irrigation. He has not yet seen a case of chronic empyema develop in a patient in whom the catheter has been left in place until the cavity was obliterated. The insertion of the catheter is readily accomplished and practically as easy as a simple aspiration. It is true that the after treatment requires meticulous care and unless this is given the closed method of treatment will not be successful. Patients should be hospitalized and under the constant attention not only of a surgeon conversant with this form of treatment but of interns and nurses as well. During the early days of the treatment, particular watchfulness is necessary to guard against the stoppage of drainage by mucous plugs, and the aspiration of air into the pleura from either a leak in the system or neglect in keeping the drainage catheter under the fluid level. As the patient becomes stronger, the latter part of the treatment may be carried out in his home. The duration of the drainage varies not only with individuals but especially with the seasonal differences in the type of infection. However, the pseudomembrane having been removed and the intercostal incision immediately sutured, the closed method can then be carried out successfully. In these patients the duration of postoperative drainage was, as a rule, exceedingly short.

**Gastro-Intestinal Polyps**—Lawrence found the incidence of polyps in 7,000 necropsies to be 33 per cent. Microscopic study of only those polyps which macroscopically appeared suspicious showed malignant transformation in 65 per cent. Speaking for the possibility of a direct relationship to polyp is an additional 12 per cent of carcinomas associated with polyps. The number of polyps more closely approaches the number of malignant conditions in the sigmoid and rectum than in any other region of the gastro-intestinal tract. This relationship is least striking in the small intestine and in the transverse colon. Polyps are found most frequently in persons between 50 and 60 years of age, and in the group more than 40 years of age white males were 157 times more commonly affected than white females, 15 times more than Negro males and 25 times more than Negro females. Polyps were approximately twelve times more common in the colon than in the small intestine.

## Use of Powdered Milk and Alkali in Peptic Ulcer—

Woska and Emery believe that their modification of the Sippy regimen will retain the value of the treatment and eliminate the many feedings, which is the main disadvantage of the Sippy treatment. They investigated the effect of powdered milk on the gastric juice, for if this could be substituted for whole milk and cream it would be a simple way for a patient to take an alkalinized milk product. They compared the effect on the gastric acidity of 90 cc of whole milk and cream with the effect of 125 Gm of powdered milk. The results were similar with the two preparations although with the powdered milk the free acidity drops toward the end of the day to a level slightly below that obtained with whole milk and cream. The total acidity was much the same in the two instances. They next compared the effect of an alkalinized powdered milk with the usual Sippy treatment. They mixed 0.6 Gm of calcium carbonate and 2 Gm of sodium bicarbonate with the 125 Gm of powdered milk and the entire mixture was given to the patient in 90 cc of water. Water was allowed in small quantities, usually in the form of cracked ice in addition to the milk and alkalis. The free acidity remained low under both methods. The curve for total acidity was the same whether whole milk and cream or powdered milk was used. The total acidity was less when no alkali was given. The results obtained on patients in the fourth week of treatment are charted. The patients were receiving the same kind of treatment as on the seventh day with the exception that the six feedings had been changed to three meals. They were encouraged to be up and around the wards in order to approximate as closely as possible the conditions under which they would live after leaving the hospital. Hourly feedings of alkalinized milk powder controlled the gastric acidity about as well as whole milk and cream with powders given on the half hour. In the individual patient alkalinized powdered milk reduced the gastric acidity to zero in a much higher proportion of instances than with the routine Sippy treatment. A comparison of the efficacy of the routine Sippy treatment with the alkalinized powdered milk shows that 90 cc of milk and cream and of powdered milk without alkali were equally efficacious. Milk and cream adequately controlled 47 per cent of the patients compared to 50 per cent on powdered milk. However when alkalis were added the alkalinized powdered milk gave much more satisfactory results. On the first day, 75 per cent were adequately controlled with alkalinized powdered milk as opposed to 54 per cent by the routine Sippy treatment. On the seventh day the figures were 94.1 per cent by alkalinized powdered milk as opposed to 71 per cent by the routine Sippy treatment and on the fourth week 94.1 per cent as opposed to 57 per cent.

**Hypertension Based on Nitrogen Distribution of Serum Proteins**—Rafsky and his associates observed changes from the normal in 84 per cent of seventy-six cases of hypertension in either the basic amino or monamino nitrogen fractions of the blood serum proteins or in both these fractions. The change in 23 per cent was in both fractions, in 18 per cent only the basic amino nitrogen was altered, in 42 per cent

the monamino nitrogen alone was changed and in 15 per cent no change was demonstrable. Based on these chemical changes, a classification of cases of hypertension is proposed. In the cases of hypertension with a low basic amino nitrogen, there was little or no evidence of nephritis. A review of the clinical aspects of the cases of hypertension having increased monamino nitrogen showed in the greater majority of the patients a mild degree of nephritis without retention of the nonprotein nitrogenous constituents. In the group of hypertensive cases in which both nitrogenous fractions deviated from the normal there was usually evidence of marked nephritis with nitrogen retention in the blood to a varying degree.

**Sedimentation Time in Cardiac Infarction**—Shookhoff and his collaborators studied the sedimentation times (Linzmeier) in twenty-nine cases of acute coronary thrombosis confirmed by electrocardiography. Of nine patients who died, necropsies were obtained in five and an acute coronary thrombosis was found. The sedimentation time was abnormally rapid at some time during the course of the disease in all the cases. Even when the diagnosis is clear they believe that it is of definite value to follow the sedimentation time. They have found it to be a sensitive indicator of subsequent thrombosis in the heart or elsewhere or of embolus or infection. It enables one also to estimate the rapidity of healing. At the present time there is no definite evidence that the rapidity of the sedimentation time is proportionate to the extent of the damage in the heart but it seems justifiable to assume that, while the determination is abnormal, active changes are taking place in the heart muscle. The sedimentation time makes less arbitrary the duration of rest in bed for a particular case and a patient with an acute coronary closure should be kept in bed at least until this determination has returned to normal. Before a cardiac significance is attached to a rapid sedimentation rate, a search should be made for infection and infarction outside the heart.

Shambaugh Jr Chicago—p 222

**Primary Skin Graft in Modified (Bondy) Radical Mastoidectomy**—Shambaugh asserts that the Bondy modification of radical mastoidectomy is indicated in cases of cholesteatoma in which the perforation is limited to Shrapnell's area (genuine cholesteatoma in Witmaack's classification). The use of the primary skin graft hastens complete epithelization and prevents troublesome granulations thus favoring preservation of the hearing. In two cases of genuine cholesteatoma in the ear with the better hearing in which surgical intervention was required the Bondy modification of radical mastoidectomy with the use of a primary skin graft resulted in completely epithelized dry cavities in twenty-five and in thirty-two days and not only preserved but appreciably improved the hearing in the ear on which operation was performed.

**Trachoma Treated by Zinc Ionization**—Edison states that in all clinical stages of trachoma zinc ionization produced complete arrest in thirty-one cases about 70.5 per cent of those

given four treatments, one each at weekly intervals. Amelioration of all subjective symptoms, with notable beginning regression of the follicles and cicatrization, was obtained in nine cases, about 20.5 per cent. Four patients (9 per cent) did not respond to the treatment. In seven patients, no recrudescence occurred after eighteen months of apparent cure. Zinc ionization was employed in the acute or chronic stages and in the presence of corneal ulcer or pannus. The course of the disease was shortened in all cases. None of the thirty-one patients discharged required further active treatment after the tenth week. Since the electrodes are in contact throughout the treatment with the entire conjunctiva including the fornices, lids, inner and outer canthi and the caruncle, the entire pathologic area is reached during each ionization. No complications or sequels resulted from the treatments.

**Relation of Drugs to Leukopenia**—Kracke and Parker assert that it seems reasonable that all drugs containing the benzene ring with the amine attachment are potentially capable of producing the leukopenic state in both men and lower animals. These include mainly aminopyrine, dimetophenol and acetphenetidin and the gold salts have been reported as producing the disease in cases of tuberculosis. The gold salts have as their central structure this benzamine ring with the attached gold molecule. Arsphenamine is capable of producing the disease as well as other forms of bone marrow aplasia. Arsphenamine has for its central structure a double benzene ring with the arsenic attached, and it seems probable that its depressant action is due to its benzamine structure. Many questions have arisen in connection with the drug relationship to agranulocytosis and one of these has been its mechanism

of action. A summation of opinions indicates almost unanimous agreement that benzene ring drugs produce agranulocytosis. There is ample evidence to indicate a close relationship between leukopenic states in agranulocytosis and other blood dyscrasias. The increasing number of cases of myeloid leukemia that eventuate into the aleukemic state illustrates the tremendous range of bone marrow activity that may be seen in the same patient. Patients having aplastic anemia and aleukemic leukemia should be carefully questioned as to ingestion or contact with benzamine ring substances. One may become poisoned with benzene by inhalation, ingestion or injection.

**Blood Coagulant Extract from Placenta in Treatment of Hemophilia**—Eley and his collaborators have observed a striking difference in the results with tissue protein extract prepared from the human placenta and those reported from the use of animal tissue preparations in the treatment of patients with hemophilia. Animal tissue extracts have shortened the coagulation time of the blood of patients with hemophilia for very brief periods whereas human placental extracts have reduced the clotting time of both venous and capillary blood for periods varying from forty-eight hours to as long as nine days. Despite repeated slight trauma incident to active childhood two children with hemophilia have been able to lead normal, active lives for periods of several months by the continued administration of this material at carefully regulated intervals. In fifteen cases of hemophilia reported, the blood coagulant extract has been well tolerated by oral administration or by intramuscular injection. It must be emphasized that this blood coagulant extract is fatal when injected intravenously in patients with hemophilia. Therefore in using this material in patients with hemophilia intravenous injection must be avoided as this route is unfortunate, if not fatal, results might ensue. Eleven of the fifteen children with hemophilia have shown a satisfactory response to either the oral or the intramuscular administration.

of the extract, as evidenced by a reduction of the coagulation time to within ten minutes, which the authors take as the upper limit of normal. In the other four instances there was a reduction in the coagulation time, but the end point was not sufficiently low to consider the effect as satisfactory as in the other group of cases.

**Acute Lymphocytic Meningitis**—The attention of Toomey was attracted to this disease by its rapid epidemic spread in an orphanage which housed 360 male children from 3 to 16 years of age and sixty-five adults. The symptoms of the disease were excruciating headache, anorexia with nausea or vomiting or both, pain in the epigastrium on palpation, a low grade fever, a throat moderately or severely inflamed, some pain on movement of the head, a total white count perhaps lower than usual, but if normal, in most cases with a relative increase in the circulatory lymphocytes, negative neurologic signs, a spinal fluid pleocytosis with lymphocytes predominating in the severely affected case and a hemolytic streptococcus that was easily isolated from the throats in a small proportion of the cases. It appears to the author that this may be a new syndrome or a more severe manifestation of acute aseptic meningitis. It should be kept in mind and differentiated from poliomyelitis.

- Fundamentals of Internal Medicine. Diseases of the Nervous System. A. Schneider. Washington—p. 42.

**So Called Chronic Cystic Mastitis**—In discussing the relation of so called chronic cystic mastitis to malignant condition Horwitz states that every one agrees that conditions of the breast described as mazoplasia are benign. The cystic states of the breasts may be divided into the nonhyperplastic type in which the lining epithelium is flattened and atrophic and even absent, and the hyperplastic type, in which there is formation of intracystic papillomas, the so called papillary cystadenomas. Opinion on the relation of these cysts to malignant conditions is divided into three groups. 1 Those who agree with Cheate and Cutler that all cystic disease of the breast is precancerous and should be treated radically. 2 Those who agree with Bloodgood who from clinical experience has concluded that there is no relationship between cystic disease of the breast and malignancy. 3 Those who consider the nonhyperplastic cystic

states as benign and who would treat radically only those cysts which show hyperplasia. Kilgore believes that although the preponderance of evidence is in favor of Bloodgood's concept, a good deal of clinical judgment should be used in the treatment of hyperplastic cystic disease. If it occurs in a woman at an age when the breast function is no longer important and the incidence of cancer is apt to be high, the sacrifice of the breast would be logical. One could be more conservative in the case of younger patients unless a malignant condition is definitely suggested or if a large portion of the breasts is involved. In the light of recent study of the physiology of the breast, painful lumps or 'shotty' breasts are the result of disordered function and can be treated conservatively with attention to the secretions of the ovary and pituitary glands.

**The Lack of Sanitation in Beer Gardens**—Benning points out that a recent sanitary survey of beverage establishments undertaken by Mallmann and Devereux brought to light the following insanitary conditions: 1 Few establishments in which beer or liquor was sold were attempting proper care in the handling of glassware. 2 Few places in the entire city had satisfactory glassware. 3 Many were not even provided with running water at the dispensing bar. Some were merely dipping the glasses in a pail of water which was changed at infrequent intervals. 4 In a few wash sinks were located in back rooms inaccessible to the bar. 5 Appearance of the bar and the wash sinks showed plainly that even rinsing the glasses in water was a rare occurrence in some cases. The author suggests the following sanitary measures for beer gardens, restaurants and places in which alcoholic beverages are sold in rural areas which do not come under a full time health department or where no such ordinance exists even if a full time health department is in operation: 1 The person or persons who are to work in these places must obtain a certificate of health from the health department. This food handler's permit shall consist of an examination for venereal disease, tuberculosis and any other communicable disease. In addition all workers must be examined to determine whether or not they are typhoid carriers. 2 The conditions existing in the beer garden, restaurant, barbecue or other such place must be sanitary and arranged for the bodily well being of patrons as approved by the health department where one exists or by some public health agency to be designated. 3 The washing facilities for glasses, dishes or other eating utensils must be such as will be approved by the state department of health and local health authorities. The author believes that the menace to the health of the people under present conditions in the majority of drinking places is remediable at a cost not out of proportion to the benefit to be obtained.

- Heart in Rheumatic Fever. C. L. Derier. Portland—p. 310.

**Emotion and Diarrhea**—Sullivan reviews the early medical views on simple diarrhea, presents observations from the literature on this psychomotor phenomenon and discusses recent work on the etiologic relationship of emotion to certain diarrheas usually considered organic in origin. Nervous diarrheas, organic diarrheas, mucous colitis and ulcerative colitis are dis-

cussed, and indications for future investigations are given which suggest that, if the colon is substituted for the tear glands and diarrhea for weeping, an idea will be had of how the problem should be attacked. The author does not believe that psychologic studies will provide the answers to all the questions. There is much to be done on the somatic side—the mechanisms involved in the hyperperistalsis, the hypersecretion of mucus and the production of ulceration have still to be solved. There is plenty of scope for investigators who will continue the work so ably begun by Cannon, Alvarez and Cushing. However, in the care of patients there is an immediate need for physicians interested in the psychic investigation and treatment of such psychosomatic disorders. In this group are included not only diarrheal diseases but also essential hypertension, the exophthalmic syndrome, gastric and duodenal ulcer and cardiospasm.

**Prevention of Intranasal Infection with Neurotropic Viruses**—Armstrong and Harrison compared the efficacy of various agents but found from 0.32 to 0.64 per cent trinitrophenol (picric acid) either alone or combined with alum to be superior to 4 per cent alum and to be the most satisfactory and efficient experimental agent. In the concentration and amounts employed it was devoid of detectable general or local injurious effects on animals. Sixteen applications sprayed by means of an atomizer into the nostrils of the authors produced no detectable injurious effects. They believe that the acid exerts its protective effects locally either by rendering the mucous membranes less permeable to infection or possibly by a direct action on the virus itself or both. Its use does not prevent the development of specific immunity in mice following a subsequent intranasal instillation of encephalitis virus. The acid given to mice one and two days before one and two days after or on the same day as the virus instillation led to a decreased susceptibility to the virus in all instances as compared with non-prepared controls. The protective effect of 0.32 per cent trinitrophenol is apparent against intranasally inoculated poliomyelitis for at least from four to seven days following its last administration. Intranasally instilled chemicals effective in preventing encephalitis in mice have been found effective against poliomyelitis in monkeys suggesting that the former may be utilized as an indicator in a further search for more effective prophylactic agents in the latter ailment.

**Blood Picture in X-Ray and Radium Workers**—Kaplan and Rubenfeld observed a group of radium workers, both technicians and clinicians over a period of from one to four years. They have divided the series into group I, those doing roentgen diagnosis; group II, radium element technicians; group III, radium emanation technicians; group IV, radium and roentgen therapy technicians; and group V, radium pack nurses. Under satisfactory working conditions tolerable exposures of about 0.2 roentgen daily (as recommended by the International and British Committees) were found to be far below this tolerance dose in groups I, III and IV. Technicians working with the X-ray diagnostic machines manifested little or no reactions. One individual with a decrease in polymorphonuclears and an increase in lymphocytes, failed to rectify this alteration even after greater precautions, vacation or change of routine. The workers with radium element showed no deviation in the hemoglobin, red cell count or white cell count. Although the hospital radon technicians showed frequent white cell variations, the hemoglobin and red cell count were not reduced. This group stands as the one in which a low white count approaching a leukopenia with a relative lymphocytosis was fairly constant. Return to normal after a vacation was the rule. No hemoglobin or red cell diminution was observed in the technicians preparing commercial radon. Unlike the hospital group the total white cell level was maintained but a change in the white components was common. Of four technicians who manipulated both high voltage therapy machines and radium applicators two showed changes while two remained unaffected. The blood changes were demonstrated by a decrease in the polymorphonuclears and an increase in the lymphocytes, an occasional decrease in total leukocytes and a sporadic eosinophilia. An old malaria may well explain the latter in one individual. The one instance of a red cell anemia appeared in a nurse who manipulated the 5 Gm radium pack. She was the only one to show a complete inversion of the polymorphonuclear and lymphocyte ratio. The usual record in the other workers was a decrease in the polymorphonuclears and an increase in the lymphocytes, without any other changes. These changes appeared soon after commencing routine in the new field. None of the twenty-two individuals included in this survey showed any grave effects from their particular field of work. The most constant and evidently the most characteristic alteration that occurs in the peripheral blood after exposure to stray radiation from either radium or X-rays is a decrease in the polymorphonuclears and an increase in the lymphocytes. Since a definite reduction in the total white cells was recorded in but two individuals and an eosinophilia occurred in but two others the authors do not cite that as a definite blood change. This negation is further substantiated by the far greater percentage of white cell changes that appeared in twenty of the twenty-two persons studied. Whether one is justified in laying emphasis on the blood count reading as an index of reaction is a question. The symptom of undue tiredness which was dominant and often concomitant with alteration in the polymorphonuclear-lymphocyte ratio was persistently noticeable.

These workers took heed of this change, emphasized greater precautions in the course of their work, enjoyed more sunshine and fresh air, and were often rewarded by a dissipation of the fatigue and a more normal blood count level. Until some more sensitive index is made available, close scrutiny of the ratio between the polymorphonuclears and the lymphocytes should be made at regular intervals. When fatigue accompanies an altered ratio in these components, it will be well to emphasize precautionary and recovery measures.

**Treatment of Peptic Ulcer**—According to Ochsner and his collaborators the treatment of peptic ulceration has in too many instances been focused on the ulcer itself without realization that the ulcer is merely a symptom. The causes for peptic ulcer can be divided into two groups: one in which the factors are not amenable to therapy but are inherent and predisposing, and the other in which they are precipitating but can be corrected. The inherent or predisposing factors are tissue susceptibility and constitutional predisposition. The precipitating factors are hypersecretion, hyperacidity, focal infection and gastric trauma. Tissue susceptibility, which is an inherent quality present in all individuals, is the vulnerability of certain portions of the gastro-intestinal tract to peptic digestion, such as the lesser curvature, pylorus, duodenal cap, jejunum and other portions of the intestinal tract subjected to the acid gastric chyme as Meckel's diverticulum containing islands of gastric mucosa. Constitutional predisposition, although difficult to define, is unquestionably present in most if not all patients with chronic gastroduodenal ulceration. As the predisposing factors are not amenable to therapy, the treatment of peptic ulcer consists in the prevention and the correction of the precipitating factors. The peptic ulcer patient must abstain from activities that increase gastric secretion and acidity. In addition to this abstinence, neutralization of gastric acidity is favored by a diet consisting of frequent small feedings as food is an important neutralizing agent. Administration of mucin is of value in controlling hyperacidity in many cases. Restoration of the normal function of the pyloric sphincter is of importance in the therapy of peptic ulcer because it relieves gastric retention and also diminishes secretion which is stimulated by gastric retention. The relaxation of the pyloric sphincter permits free regurgitation of the alkaline duodenal secretion into the stomach and favors neutralization. All foci of infection must be removed because they can act either directly, by producing a specific

inflammation in the stomach or duodenum, or reflexly, when within the abdomen, by producing pylorospasm. To minimize gastric trauma, only bland foods containing no roughage should be allowed. Because of the constitutional predisposition to ulceration, it is imperative that the patient change his mode of living. The surgical treatment of peptic ulcer consists largely in the treatment of complications, such as mechanical obstruction, perforation, repeated hemorrhages and danger of malignant change. In a case of pyloric occlusion with prolonged gastric retention and hypoacidity, gastro-enterostomy is the procedure of choice. In cases with hyperacidity or normal acidity, because of the increased susceptibility of the jejunal mucosa to the acid gastric chyme, the resection of the pyloric sphincter or the performance of a gastroduodenostomy is to be preferred to gastrojejunostomy. The duodenal mucosa is more resistant to the acid gastric chyme than is the jejunal mucosa. The chronic calloused ulcer in the stomach, which does not respond readily to therapy, should be operated on and radical resection done, because of the danger of malignant change.

**Surgery as Related to Hypertension**—Adson and his associates submit the results of a number of surgical procedures carried out in cases of hypertension. The purpose of operation is to destroy the vasomotor innervation to a large vascular area in order to make those vessels which are deprived of their vasoconstrictor impulses unable to respond to the central mechanism and therefore unable to take part in the general phenomena of vasospasm. While the vessels that have not been denervated continue with spasm, the denervated vessels dilate instead and act as reservoirs. The musculature of the heart and blood vessels is capable of responding directly to the pressor and depressor substances circulating in the blood stream and there is a possibility that these substances increase or that the musculature becomes more active, as a compensatory factor following extensive forms of sympathectomy. It is therefore further possible that this is the explanation for the surgical failures. Operative procedures on the adrenal suggest that a diminution of the secretion of epinephrine is a beneficial factor in the treatment of the disease. The evidence to date, however, is not conclusive or indisputable. Analysis of the data following surgery indicates that certain definite results have been obtained by these extensive operative procedures. A limited number of patients fail to respond to the same procedure, while still others have obtained clinical improvement without a material drop in blood pressure, some of them having had a return of their old symptoms and of their high blood pressures. The interval following these surgical procedures is too short to prognosticate what the ultimate results will be. One of the authors' patients has now survived for approximately five years, but the remaining patients have survived twenty-five months or less. The immediate effects in many cases have justified the surgical treatment and they have encouraged the authors to continue with the operative measures in the hope that better selection of cases may be made and that subdiaphragmatic splanchnic resections with removal of the upper two lumbar ganglia and resection of the adrenal may be more effective in controlling or relieving symptoms of essential hypertension than the operation of bilateral ventral rhizotomy of the thoracic and lumbar roots extending from the sixth thoracic to the second lumbar, inclusive.

**Cerebral Injuries Due to Trauma**—Swift bases his treatment of cases of cerebral injury due to external trauma on the theory that: 1 The damage is largely done by direct hydraulic pressure and in direct proportion to the character of injury. 2 A disturbance to the normal cerebrohydrodynamics must be rectified at the earliest moment. 3 A maintained cerebrospinal fluid balance is essentially a determining factor as to both mortality and morbidity. 4 Cerebral hemorrhage when fatal, occurs within the first three hours and in less severe cases may be controlled by proper spinal drainage. 5 The presence of a hydrated brain previous to the injury necessitates the most careful and constant observation. 6 The controlling factors are blood pressure, pulse pressure and sustained nourishment of the patient during the hours of repair. 7 Spinal drainage, hypertonic solutions and whole blood transfusions are the most

valuable procedures. They must be ordered only after careful evaluation of the demand for each one and under the constant supervision of trained nurses, interns and surgeons.

 Bright's Disease Pathology and Treatment J L Miller Chicago —p 638

**Encephalitis Following Neosarsphenamine**—Cowper and Yaskin cite two cases of combined occurrence of encephalitis and blood dyscrasias following the use of arsphenamine. In case 1 there was involvement of all the blood elements producing aplastic anemia of the severest kind which did not respond to any form of treatment. In case 2 there was transient and very mild involvement of most of the blood elements caused by a mild depression of the bone marrow. Both cases when first seen presented manifestations of grave brain disease of unknown etiology. The coexistence of evidences of blood dyscrasias in similar cases may make one suspicious of arsphenamine intoxication. Encephalitis and blood dyscrasias following the administration of arsphenamines vary considerably in their severity. The encephalitis is a result of the involvement of the reticulo-endothelial system; it may be severe with pericapsillary hemorrhages and be rapidly fatal or it may be mild with edema of the brain and may terminate in recovery. When only the blood platelets are affected (thrombocytopenia) purpura with hemorrhages follows and recovery is the rule. When the bone marrow is slightly depressed there may be only a reduction of the white cells with a fair chance for recovery. In severe bone marrow depressions when all cellular elements of the blood become affected (aplastic anemia) the outcome is unfavorable. Considering the great number of arsphenamine injections, these complications are relatively uncommon. While there is no way of predicting their occurrence in the majority of cases owing to their seriousness it is necessary to bear in mind certain precautions. The arsphenamines should be used only when there is a clear indication after taking all facts and factors into consideration. Subjective complaints on the part of the patient receiving the arsphenamines should call before any further treatment is given at least for a careful inspection of the skin and mucous membranes and a complete blood count. The treatment of the complication consists in the administration of sodium thiosulfate transfusions and supportive measures.

 Total Leukocyte and Filament Nonfilament Neutrophil Count Following Surgical Operations Without Complications Camille Mermod San Francisco —p 691

**Hypoplasia of the Endometrium**—Wilson observed the endometrium in 139 cases of functional bleeding. He states that in addition to substantiating his impression concerning the incidence of hyperplasia in uterine bleeding the study has elicited an endometrial picture which is probably common for the majority of cases of so called functional bleeding. There is, he believes, ample evidence in the medical literature to substantiate this premise. The etiologic factors involved in the development or underdevelopment of the endometrium as well as the causes of bleeding in these cases are obviously difficult to determine. Although historical data that he records are probably inadequate for confirmatory evidence pointing to

definite gonadal dysfunctions, he is convinced that further studies will show that the endometrial picture described is the result of an ovarian dysfunction associated with a diminution in the production of the follicular hormone. The histories and pelvic examinations in a number of cases point in this direction. Likewise the endometrial picture in a majority of cases lacks all signs of proliferation, development appearing to have ceased in the interval phase of the cycle, well before ovulation. This suggests an inadequate supply of estrogenic substance for the normal cyclic proliferation of the endometrium. Quantitative determinations for estrogenic substance in the blood urine and menstrual discharges of these women would probably furnish further enlightenment. The actual bleeding might be explained on the basis of a diminution in estrogenic substance. It is now generally believed that menstruation in the human being is due to a drop in the estrogenic substance blood level and the author suggests that the same factor is responsible for many cases of premature and otherwise abnormal bleeding. The fact that estrogenic and anterior pituitary-like substances effect a reduction or a cessation of bleeding in some cases of this type is additional evidence in favor of hypo ovarianism.

### Estrogenic Substances in Treatment of Pelvic Disease

—On the presumption that estrogenic substances stimulate the defensive mechanism of the pelvic organs Fluhmann and Hoffmann undertook to study the use of estrogenic substance in twenty-nine adults with acute and chronic pelvic inflammatory disease. The substance employed was a preparation of amniotin (Squibb) dissolved in oil and containing 500 or 1000 rat units per cubic centimeter. It was administered intramuscularly in 0.5 or 1 cc doses daily until the patient had had from five to sixteen injections and a total dosage varying from 3,750 to 16,000 rat units. Twenty-four patients were ambulatory with chronic or subacute salpingitis, while five were hospitalized and represent a group of acute febrile cases. In twenty-three instances there were definite palpable adnexal masses at the time the injections were begun. On reexamination in from two to six weeks after the course of treatment, complete healing with a disappearance of the masses resulted in seven cases, while nine showed definite improvement but with palpable pathologic changes of the pelvis. On the other hand, no improvement was noted in seven cases, in five of which operation was eventually performed. Of six women in whom no palpable masses were demonstrable but definite tenderness and induration were elicited in the region of the adnexa on pelvic examination only three showed any degree of improvement within from two to six weeks after treatment. Of twenty-seven women nine stated that they had obtained complete relief from pelvic pain within from two to six weeks. In three instances this appeared after the third or fourth injection and it was observed even with persistent pelvic masses. Twelve patients obtained partial relief from pain while complete failure was noted in only six instances. Of nineteen cases of profuse vaginal discharge definite improvement within from two to six weeks was noted in seven instances whereas the amount of discharge was unaffected in twelve cases. A positive smear for gonococci was obtained before treatment in thirteen cases and six became negative from two to six weeks after treatment. No evidence was obtained that the administration of as much as 9,500 rat units of the preparation during the course of a cycle produces any disturbance in that cycle or in the succeeding menstrual period.

**Overlapping in Irradiation of the Scalp**—Epstein points out that in epilation irradiations of the head with longer focus skin distances so much overlapping occurs that some areas under certain circumstances of irradiation receive up to 180 per cent of the dose applied to the different centers and thus receive up to nearly 500 roentgens (incidence dose). In spite of these overdoses there are no bad consequences to be feared for normal cases, as experience shows. This is intelligible as a result of observing a child, aged 4 years, who received on one field of radiation 540 roentgens (incidence dose). Even with this dose there was only a temporary epilation, without any reaction and with subsequent full regrowth of the hair. These observations tend to bear out from the clinical point of view the statement, demonstrated by experiments of various authors, that the sensitivity of the skin is the same for the rays applied for dermatologic therapeutics (of about 100 kilovolts) as well as for harder rays.

**Depth Dose in Radium Teletherapy**—By measurements with various wax phantoms of the radiation intensities due to the 2 Gm. bomb at Westminster Hospital Annex, Wilson studied the relative magnitudes of the primary and secondary radiations comprising the total depth dose. It is shown that the intensity measured at a depth in wax is nearly always less than that measured at a corresponding position in air, therefore scatter does not compensate for absorption in this case. Even at depths as great as 10 cm., more than 80 per cent of the total dose consists of forward directed radiation of a quality that appears to differ but little from that of the primary radiation received by the skin. A small part of entry may be of value in the construction of a radium bomb if it is most desirable to use only the hardest radiations at a depth since such an arrangement helps to reduce the amount of softer scattered radiation to a minimum.

**Perifocal and Traumatic Hemorrhages in Pulmonary Tuberculosis**—Pagel and MacCallum state that the varying and complicated mechanism of pulmonary hemorrhages in tuberculosis has heretofore received inadequate attention. It seems desirable to collect cases providing anatomic proof of hemorrhages, in which there is no evidence of the simple rupture of a cavity aneurysm or of a vessel with tuberculous involvement of the wall. They report two cases. 1. A case of fatal hemoptysis in pulmonary tuberculosis did not show the simple condition of the rupture of a cavity aneurysm but disseminated perifocal and intrafocal hemorrhages which must be referred

to allergic hypersensitiveness associated with the process of recent liquefaction. A small aneurysm only microscopically visible in an early cavity, like the capillary alterations in the other foci, appeared to have developed rapidly during recent processes of liquefaction and therefore was not to be regarded as accidental. 2. This case permitted an examination of the influence of a trauma on old tuberculous foci, demonstrating the hemorrhagic destruction of the latter. The tissue of the foci appeared to be more fragile than the normal pulmonary tissue, the latter showing the most marked destruction in the neighborhood of the foci (perifocal hemorrhage).

**Carbon Tetrachloride Cirrhosis in Relation to Liver Regeneration**—Experiments by Cameron and Karunaratne show that carbon tetrachloride in small amounts produces marked lobular degeneration and necrosis of the liver, followed at once by proliferation of the unaffected liver cells and complete repair, in the case of the rat in from one to two weeks. The smallest amount necessary to produce histologic evidence of damage to the rat's liver is about 0.025 cc. per kilogram of body weight, a dose within the limits of the therapeutic dose for man. Multiple exposures call forth in the rat's liver

changes the nature of which is determined by the size of the dose and the interval between successive doses. A certain minimal amount, greater than the minimal toxic dose for the liver, must be given at short intervals to induce permanent effects. When there is time for recovery after each dose, carbon tetrachloride can be administered indefinitely without producing any permanent alteration. If, on the other hand, time spacing does not allow of complete recovery after each dose cirrhosis of the liver results. There are two stages in the development of carbon tetrachloride cirrhosis: (1) a precirrhotic reversible stage, with histologic features indistinguishable from actual cirrhosis and (2) a cirrhotic stage, with a finely or coarsely granular liver. In the former, the liver reverts to normal on discontinuance of the drug. Restoration is due mainly to proliferation of liver cells, although it seems that fibrous tissue bands may actively disappear. The cirrhotic stage is characterized by the permanent nature of the peribulbar fibrosis which persists for months after the carbon tetrachloride has been discontinued. There is also diminished or absent growth capacity of the liver cells in autoplasmic liver grafts and impairment of restoration in the liver as a whole after partial hepatectomy. There is evidence that in at least two other types of experimental cirrhosis (tar and sudan III) similar stages in the progress of the condition may be recognized.

**Streptococci from Pasteurized Milk**—Wright declares that the presence of organisms of the *Streptococcus thermophilus* group is an important cause of the difficulties in the bacteriologic examination of pasteurized milk. The standard mediums are unsuitable for the cultivation of the majority of these organisms. The growth requirements of different strains show considerable variation, some growing well on infusion mediums while others need the addition of milk lactose or sucrose. Fermentable disaccharides (lactose and sucrose) facilitate the growth of the more fastidious strains but the slowly fermented disaccharide maltose and the fermentable monosaccharides (dextrose, fructose and galactose) do not. Infusion agar is a better basis for the preparation of mediums for the cultivation of these organisms than either standard or yeast agar as the colonies are considerably larger. The occurrence of minute colonies in routine milk counts may also be dependent on the presence of other organisms with special requirements in regard to temperature and aeration during incubation.

**Pathology of Rhinosporidiosis**—Karunaratne points out that rhinosporidiosis is a disease almost invariably in men occurring in India, Ceylon and North and South America. It usually affects the nasal cavity, less frequently the conjunctiva and rarely other sites. It produces a friable polypoid mass that bleeds easily. Only fifty-three cases have been reported in the literature, although the author has seen thirty-four instances during the last thirteen years. He discusses the structure and life history of *Rhinosporidium* and the morbid anatomy and the histology of the lesion. In the nose the polyp tends to become obstructive. Often a well marked coryza precedes and accompanies the obstruction. The discharge which is thin and mucoid and sometimes blood stained usually contains both spores and sporangia. Epistaxis is seen in only a few cases and a definitely purulent discharge is rare. When the growth occurs in the nasopharynx it may hang downward and cause difficulty in swallowing. In the conjunctiva the tumor readily attracts attention and in the few cases in which infection of the lacrimal sac had occurred obstruction resulted from blocking of the sac by growth and was accompanied by suppurative dacryocystitis. A tendency to recurrence is a characteristic feature. The tendency to recurrence would suggest that the parasite undergoes its complete cycle of development in the human body without the intervention of an intermediary host. Another important characteristic is the long history. Trumurti mentions an instance in which the patient had the infection for twenty years and in Knowles' case the infection had lasted sixteen years. The infection remains localized to the original site though nearby sites may become infected but there is no evidence of generalized hematogenic dissemination. Nothing definite is known about the modes of infection and transmission. As the nose and eye are the commonest sites it is possible that the organism is transmitted in dust or water. The presence of infection in nearby sites would point to the possibility of auto-

inoculation. It has not been possible to grow the organism in artificial mediums, with the doubtful exception reported by Ashworth, nor has it been possible to transmit the infection to the lower animals. Infection in farm animals has been observed and it is possible that there is some definite etiologic relationship between the disease as it occurs in man and in the lower animals.

**Effect of Stopping of Blood Supply of Rat Tumors**—A strain of Jensen's rat sarcoma, which normally progresses and causes death in more than 90 per cent of the animals was used by Chambers and Scott in temporarily stopping the blood supply to the tumor (for from two to four hours) with as little local damage as possible. An ordinary large screw clip was used, the metal bars of which were covered with thick rubber tubing holding a water jacket. Only one water jacket was used, the other side of the clip was left empty. The temporary stopping of the circulation of actively growing Jensen's rat sarcoma when effectively carried out, often caused the disappearance of the tumor. This appeared to be mainly dependent on the complete block of the vascular supply, but also to some extent on the amount of surrounding tissue included in the clip and on the size and rate of growth of the tumor at the time of treatment. After the disappearance of the tumor the rats are invariably immune to inoculations of Jensen's rat sarcoma. The total number of tumors treated was 251, of which seventy-three disappeared. A 30 per cent spontaneous disappearance is out of the question, as records show that spontaneous regression of this tumor is rare.

**Treatment of Dysmenorrhea by Alcohol Injection**—Davis states that the object of injecting alcohol for the relief of dysmenorrhea is to block the nerve pathway to the uterus at its nearest accessible point. The portion of this pathway which most conveniently lends itself to external intervention is the pelvic plexus of Lee Frankenhauser, which concentrates most of the uterine nerve supply in a comparatively small area. With the patient in the lithotomy position and anesthetized by the sodium salt of a barbituric acid derivative, the cervix is seized with volsella and retracted toward the left. The right fornix is further exposed with the aid of a flat lateral retractor. A long graduated gasserian needle is then passed horizontally through the vaginal mucosa at the side of the cervix for a distance of 0.5 cm and the retractor is removed. The needle is now passed backward and outward for approximately 1.5 cm at an angle of 45 degrees to both the sagittal and coronal planes and guided by a finger in the rectum to a point 0.5 cm from the side of the rectal ampulla. The needle is then withdrawn for 0.5 cm and 1 cc of an 85 per cent solution of alcohol is injected the needle point being kept slightly but continually moving. The same procedure is repeated on the other side. Perforation of the rectum with consequent cellular infection is avoided by making the injection 1 cm away from that organ, as calculated from the internal finger. Injury to the ureter is prevented by keeping the needle point lateral to it. The uterine artery if touched usually slips away from the needle but constant movement of the latter is a further safeguard. Only six cases have been treated over a sufficiently long period of time to allow conclusions to be drawn. The ultimate result was complete and apparently permanent relief, an effect which appears to indicate the superiority of this operation over ordinary dilation. The relief of dysmenorrhea which follows the

operation may be explained by interruption of sensory pathways, interruption of motor pathways and interruption of irregular ovarian influence. It is difficult to assess the relative importance of these factors, but it is probable that destruction of the sensory nerves is the predominant one. The reason for this assumption is that unilateral alcoholization of the parametrium relieves pain on that side only (Blos).

**Röntgen Diagnosis for Sterility**—Sasaki claims that hysterosalpingography is superior to internal gynecologic examination in its exactness and certainty in the diagnosis of sterility. Results of the hysterosalpingographic diagnosis on the uterus and salpinx in his sixty-six cases of sterility were as follows: 1 Uterine hypoplasia was found in 36.4 per cent, which accounts for its importance as one of the causes of sterility. 2 Adhesion of the uterus with neighboring organs was observed in 46.9 per cent. It is inconceivable that such an adhesion is a direct cause of sterility. Its significance lies in the fact that it is one of the complications of salpinx inflammation. 3 Retroflexions and versions of the uterus were detected in 48.5 per cent. Pregnancy, however, frequently does take place in cases of flexions or versions, which fails to prove that these lesions are the cause of sterility in such a high proportion of cases. But it is still undeniable that there is some close relation between them and sterility. 4 Closure of both sides of the salpinx in 42.4 per cent and of one side in 15.8 per cent and only 31.8 per cent of thorough penetrability of both sides of the salpinx were noted. These results explain the paramount significance of salpinx closure as a cause of sterility. 5 Adhesions of the salpinx occurred on both sides in 50 per cent, on one side in 12.1 per cent and not at all in 37.9 per cent. Further, these adhesions have a significant correlation with salpinx closure. In sterility arising from the female internal organs of generation, salpinx closure plays the most important part followed by uterine hypoplasia. Retroflexions and versions of the uterus should elicit considerable attention.

\*Nervous Complications from Freeing Pleural Adhesions O M Mistal —p 73

**Complications in Freeing Pleural Adhesions**—Mistal discusses the anatomic relations of the nerves and their points of contact in operations designed to free pleural adhesions. The phrenic and recurrent nerves are so placed anatomically as to be especially liable to injury. Lesions of the phrenic nerve usually remain obscure. Complete paralysis of the left vocal cord is the most striking effect of injury to the recurrent nerve. The brachial plexus may be injured by some routes of approach. The pains and tingling of the arms and hands that may result from such injury are temporary or permanent. The intercostal nerves may also be affected. Lesions of the sympathetic are exceptional but may occur. The usual result is Horner's syndrome. The possibility of injuring all these nerves demonstrates the dangers to which the operator is exposed and indicates the wisdom of leaving pleurolysis in the hands of the specialist.

- Exophthalmic Goiter L Justin Besançon —p 105  
\*Experimental Verification of Tuberculous Etiology of Erythema Nodosum R C Aguirre and P R Cervini —p 110

**Tuberculous Etiology of Erythema Nodosum**—Aguirre and Cervini state that in a previous communication considerable evidence of the tuberculous nature of erythema nodosum was reported in five cases. They describe another case in which the histology and bacteriology were carefully studied. Microscopic examination of the patient's nodule showed exudative pericapillary inflammation of the skin. The fatty subcutaneous tissue and deep skin showed inflammatory nodules with polymorphonuclear leukocyte predominance and panarthritis. Direct cultures from the nodules on a semisolid medium grew slowly and the surface pellicle showed acid alcohol resistant bacteria that caused tuberculosis and death when inoculated intraperitoneally in guinea-pigs. The culture thus obtained was reinjected subcutaneously into a tuberculin negative five months old calf which developed tuberculosis and local lesions not unlike those of erythema nodosum. The authors feel, therefore, that Koch's postulates have been completely satisfied and that the tuberculous nature of erythema nodosum is entirely proved.

\*Connections Between Certain Retinal and Spontaneous Leptomeningeal Hemorrhages P Karbacher —p 201

**Retinal and Spontaneous Leptomeningeal Hemorrhages**—Karbacher points out that retinal hemorrhages develop in many different disturbances and that their explanation is often difficult. In recent years attention has been called repeatedly to the retinal hemorrhages that occur in the course of so called spontaneous, leptomeningeal hemorrhages. The term spontaneous in connection with leptomeningeal hemorrhages excludes the traumatic as well as the inflammatory (in infectious diseases) forms. The author describes the histologic aspects of the eyeballs and optical nerves of a patient with spontaneous leptomeningeal and retinal hemorrhages. The case belongs to the group of spontaneous leptomeningeal hemorrhages because all other etiologic factors particularly cardiovascular or renal ones can be excluded. At the entrance of the optic nerves into the eyeballs there was not a trace of penetration of blood from the sheath of the optic nerve into the nerve or from the lamina cribrosa into the retina. Thus the histologic examination proves that it is unlikely that blood passed from the sub-arachnoidal space of the brain into the sheath of the optic nerve and from there by way of the lamina cribrosa into the eye. The case proves the simultaneous occurrence of venous stasis

in the eye in retinal and leptomeningeal hemorrhages. Nevertheless, extensive retinal hemorrhages, particularly those that penetrate into the vitreous body, are extremely rare in case of choked disk. However, since in cases of spontaneous, leptomeningeal hemorrhages bleeding into the vitreous body is rather frequent, it is difficult to connect these bleedings with choked disk. This contradiction fails to be explained and makes it appear possible that similar impairments of the vascular wall as have been assumed for the spontaneous leptomeningeal hemorrhages, are also responsible for the retinal hemorrhages.

43 183 226 (Feb. 3) 1936 Practical Section

\*Parenteral Oxygen Treatment in Pulmonary Tuberculosis E. Frola—p. 185

Infiltrating Stenosing Rectitis Cases G. Bendandi—p. 193

**Parenteral Oxygen Treatment in Pulmonary Tuberculosis**—Frola resorted to hypodermic injections of oxygen in the treatment of pulmonary tuberculosis. The injections, at a dosage of 200 cc per injection, are given in the subcutaneous tissues of the anterolateral region of the thigh with an apparatus such as is commonly used for the performance of pneumothorax, provided it is small, is deprived of its manometer and is connected with a supply of oxygen. The injections should be given slowly, to avoid sudden distention of the tissues or injury to the vessels, which may result in the formation of embolism, and should be repeated every other day for about a month. The author concludes that the treatment has an antitoxic as well as a favorable action on the cardiovascular and hematopoietic systems and on the general trophism of the patient. It results in disappearance of fever, increase of the blood pressure, improvement of the blood picture, formation of a greater number of erythrocytes and amelioration of the disease, which is proved by the results of the tests of allergy to tuberculosis and of the sedimentation speed of the erythrocytes as well as by the feeling of well being of the patient and by his gaining in weight. Hypodermic injections of oxygen also control tuberculous hemoptysis and prevent its recurrence.

Indications of Incision in Neck of Uterus in Labor O. Arcioni—p. 389

**Animal Charcoal in Treatment of Erysipelas**—The intravenous injections of animal charcoal have been advised by St. Jacques in the treatment of various infections (*Canad. M. A. J.* 31 168 [Aug.] 1934 abstr. *THE JOURNAL*, Sept. 22, 1924 p. 948). Gonzalez and Shteingart used the injections in the treatment of erysipelas and state that the entire process follows a rapid evolution to recovery: pain and the sensation of tension of the erysipelas tissues stop, the fever abates and soon after disappears, the erysipelatous patches lose their luster and regress, the general symptoms improve and desquamation soon and rapidly takes place. The authors inject intravenously an amount that varies between 3 and 5 cc of a 2 per cent suspension of animal charcoal in a 10 per cent hypertonic dextrose solution. The solution of dextrose used instead of distilled water, which was the vehicle originally used by St. Jacques, makes unnecessary the refinement in the technic used by St. Jacques, namely, that the piston, syringe barrel and needle must be paraffined beforehand to prevent clogging by the particles of carbon. Dextrose solution prevents the precipitation of the particles of carbon in the suspension and does not modify the therapeutic properties of the drug on erysipelas. The injections prepared with dextrose solution as a vehicle are easily sterilized in the autoclave and can be preserved for a long time without alteration.

### Archiv fur Kinderheilkunde, Stuttgart

\*Gangrene in Scarlet Fever and Diphtheria K. Blumberger—p. 154

**Chronic Constipation as Cause of Incontinentia Alvi**—Priesel and Siegl report the histories of several children in whom incontinence of the feces was brought on by severe constipation. The development of this form of incontinence is about as follows: For some reason a constipation develops which constantly increases in severity, so that a thorough evacuation of the bowel becomes impossible without artificial aid in the form of purgatives or enemas. In the presence of a continuous urge to defecation, small quantities of feces are constantly given off by the overfilled ampulla of the rectum. In some cases, small amounts of feces with an admixture of mucus are found around the anus. The mucus is probably secreted by the rectum in response to the irritation of the coprostatitis. The treatment should consist in the evacuation of the bowel by means of an enema, and after that the medicinal regulation of bowel movements is indicated until they have become normal again.

**Toxic Action of Corn Smut**—Dragisic and Varicak point out that corn smut (*Ustilago maydis*) has an action similar to that of ergot and that it is used as an abortifacient in the popular medicine of some regions. They report their experimental studies on the toxic effects of corn smut. They poisoned mice by means of the oral as well as the subcutaneous administration of the substance and found that it exerts a severe toxic action. They were also able to corroborate the clinical aspects of ustilaginism. The administration of corn smut resulted in manifestations similar to those produced in experimental ergot poisoning, except that the former also produced chronic and tonic convulsions, that is, symptoms which had never been observed in ergot poisoning. The similarity between the toxic action of the two substances indicates the presence of ergotamine-like substances in corn smut.

**Gangrene in Scarlet Fever and Diphtheria**—According to Blumberger, gangrene of an extremity or of another part of the body is comparatively rare after scarlet fever and diphtheria. However, there is a milder form of gangrene which involves only the skin and produces necrosis but finally ends in cure. After discussing the possible pathologic anatomic foundations of these forms of gangrene, namely, embolism, thrombosis, toxic impairment of the capillaries, endothelial proliferations or direct impairment of the skin, the author shows that on the basis of former reports it may be said that in case of scarlet fever gangrene develops most often during the third or fourth week after the onset. In diphtheria likewise the embolic form of gangrene has been known to develop during the third week. However, although there is a certain uniformity in the time of appearance of the gangrene, the localization shows considerable variety, but there are also sites of predilection, namely, the lower extremities. The author describes two cases of gangrene that he observed. The first one concerned a boy with scarlet fever who rapidly developed gangrene of the left leg and also gangrenous areas on the right thigh and foot. This case had a fatal outcome, but consent for a necropsy was withheld. It is assumed that on the left side an embolic closure must have developed above the branching of the popliteal artery. The gangrenous areas on the right extremity must have been caused by embolisms of smaller cutaneous vessels. The second case concerned a child aged 3 years, who had diphtheria and who developed gangrenous areas on both lower extremities. This case also had a fatal outcome. The bacteriologic and histologic examination of tissues from the gangrenous areas indicated that the gangrene developed in the presence of a streptococcal infection with diphtheria and as the result of hemorrhages which in turn were caused by toxic impairment of the vessels.

**Treatment of Scurvy**—Conrad reports the case of a man, aged 70, whose diet had consisted almost exclusively of white bread, canned vegetables and coffee. The patient appeared undernourished, had a subicteric color and had blood effusions on both lower extremities, on the left hand and on the right side of the chest. There also were hemorrhages from the oral mucous membrane and from the gums, and the teeth were loose and carious. Since the symptomatology together with the anamnesis indicated scurvy, the patient was given intravenously 350 mg of cevitamic acid and on the following five days 150 mg twice daily. Considerable improvement was noticeable on the fourth day. During these first days of the treatment the food was not especially rich in vitamin C. However when the intravenous injection of the cevitamic acid was replaced by the oral administration in tablet form the patient was given lemon juice and fresh vegetables. After two weeks the cevitamic acid medication was discontinued. After another three weeks the patient was discharged as cured. The author stresses that in severe cases of scurvy it is advisable to begin the administration of vitamin C in the form of intravenous injections, since this makes possible the administration of larger and more effective doses than would be the case with oral administration.

**Mesenteric Lymphangitis**—Kleiber presents observations on mesenteric lymphangitis in the surgical clinic of Pribram (Berlin) for the last ten years. Calcification of necrotic lymph nodes may follow other than tuberculous inflammation. The lymph current is not always constant and may reverse its pendulum like movement. By placing a depot of isamine blue under the serosa of the root of the mesentery and then producing an irritation of the corresponding coil of intestine the author observed the reversal of the lymph current away from the root of the mesentery and in the direction of the intestine. This experiment furnishes an explanation of the origin of the so called secondary abdominal diseases, as well as of the recurrences of local processes in tissues made allergic by previous inflammatory processes. The author was able to isolate bacteria from the lymph nodes in a number of cases the majority of which were tonsillitis. In mesenteric lymphangitis a tendency to recurrence, particularly in association with recurrent attacks of tonsillitis, is a characteristic feature. Whitish scars and strands in the mesentery are the anatomic signs of an old lymphangitis. The clinical picture of mesenteric lymphangitis resembles that of acute appendicitis. The localization of the pain corresponding to the inflamed nodes in the root of the mesentery is higher in the neighborhood of the navel. It is the cause of the so called navel colic of children. Acute lymphangitis is accompanied by a rise in temperature and leukocytosis. In about 50 per cent of the cases there was found at operation a serous or a slightly turbid exudate. The author has observed fulminant cases with signs of a general peritonitis without any tendency to localization. These cases terminated fatally regardless of whether the patients were operated on or not. As a rule acute cases with localization principally in the mesentery of the ileocecal segment subside in the course of a few days whether operation is performed or not. They display however a tendency to recurrence. The author considers an appendectomy indicated in these cases, even if the appendix does not show pathologic alterations. The lymphatic tissue of the latter may be the focal lesion. Signs of tonsillar involvement or a history of recurring attacks of tonsillitis accompanied by abdominal complaints is an indica-

tion for tonsillectomy. It frequently results in permanent freedom from abdominal complaints. The author obtained more encouraging results from protein therapy than from roentgen irradiation, diathermy or short waves in chronic neglected cases that recurred even after tonsillectomy.

Type Constancy of Diphtheria Bacilli K W Clauberg, W Helmreich and R W Vierthaler—p 231

**Paradoxical Action of Quinine**—Budelmann and Krauel point out that large and moderate doses of quinine usually elicit a reduction in the temperature but that occasionally an increase in temperature is observed. The cause of this so-called paradoxical action of quinine is not known as yet. They cite a number of authors who have observed cases of paradoxical quinine action and describe a case of their own. The woman had a mitral stenosis and always showed an increase in temperature after the administration of quinine. She also had a thyrotoxicosis. To determine whether hyperthyroidism plays a part in the paradoxical action, the authors gave small doses of quinine to several patients with exophthalmic goiter, but they never observed the paradoxical quinine action. The patient was found to be sensitive to a number of medicaments. Her serum was subjected to refractometry. The curve in which the refractometric values were recorded ran almost parallel with the temperature curve. The authors assume that in the case under consideration the paradoxical quinine action was the result of a quinine hemolysis.

**Influence of Cevitamic Acid on Coagulation of Blood**—Cotti and Larizza find that parenterally administered vitamin C (from 50 to 100 mg daily for from five to eight days) exerts a considerable influence on blood coagulation. On the basis of observations on normal persons and on persons with various types of hemorrhagic diathesis (including hemophilia) it may be concluded that vitamin C promotes coagulation. However, the authors found that this action on the coagulation can be ascribed neither to changes in the protein constituents of the plasma nor to changes in the calcium and magnesium contents. They detected considerable quantitative changes in the coagulation ferments, but they concede that further studies will be necessary to prove whether and in what manner the coagulation ferments play a part in the action of vitamin C on the coagulation.

Silver Powder in Treatment of Female Gonorrhea Trenk—p 271

**Treatment of Crural Ulcer**—Alke first treats the existing eczema by rubbing in Wilkinson's ointment with a wooden spatula. The use of this instrument has the advantage that the scales are removed more effectively and the ointment reaches the diseased skin. The patient is told to continue this treatment at home once or twice a day. After a week the eczema although not as yet entirely cured, has usually improved to such an extent that treatment of the ulcer may be begun. First the ulcer is cleaned by means of benzine. Then a ball of cotton is grasped with forceps, dampened with water and dipped into resorcinol powder. This is dabbed on the ulcer until the granulations have an opaque appearance. Then after some ointment (except zinc paste) has been applied and a thin layer of gauze placed over the wound an air-tight adhesive bandage is put on. The patient is told to return after six or eight days, when the wound is treated once more with resorcinol powder and again bandaged air tight. The treatment

is repeated at intervals of six or ten days and cure is usually obtained after several weeks. In some cases healing does not progress and a tuberculous nature may be suspected. For the latter cases the author recommends roentgen irradiations of an intensity of one third of the unit skin dose to be applied at weekly intervals. After each irradiation the ulcer is bandaged air tight, but metal ointments must be avoided in the course of roentgen irradiations. It is important that the bandage over the ulcer is air tight, and if it should become loosened is the result of a reduction in the swelling of the leg it must be replaced. After the ulcer has healed, the after-treatment is begun. The patient is told to massage the area once or twice daily with an ointment. Wilkinson's ointment has been found most effective. This after-treatment must be continued until the formation of scales ceases completely and the skin has become soft. Usually this takes two or three months and should be resumed again as soon as scales commence to form. If the after-treatment is properly carried out the cure is usually permanent.

Vitamin A Therapy of Hypertoidism H. E. Dietrich—p. 313

**Menstrual Cycle and Date of Birth**—Wahl says that since the exact date of conception is often difficult to determine the calculation of the date of delivery is usually based on the first day of the last menstruation that is it is customary to add 280 days to this date. However the author observed that the date thus computed only rarely coincides with the actual date of delivery and also that the period of 280 days is too short in many cases. He also gained the impression that the date of birth is to a certain extent dependent on the menstrual cycle. He made studies in 5000 obstetric cases investigating (1) how often a mature child is born 280 days after the first day of the last menstruation and (2) whether there is a relationship between the computed date of birth and the menstrual cycles. Summarizing his observations he says that a mature child is born after 280 days in 65 per cent of women with a cycle of twenty-eight days. However in women in whom the menstrual cycle is longer than twenty-eight days the delivery takes place at a later date in more than 75 per cent whereas in women with a menstrual cycle of less than twenty-eight days the calculated date is not reached in approximately 80 per cent. The author concludes from these observations that in women with a menstrual cycle of twenty-eight days or longer measures to induce delivery can be postponed for a while in case the gestation has gone beyond the calculated term, whereas in women with a short menstrual cycle it is advisable to take measures sooner. Moreover in forensic problems in which the average length of pregnancy has to be estimated the dependence of the length of the period of gestation on the length of the menstrual cycles should be given consideration.

**Atrophy and Hyperplasia of Fat Tissue After Insulin Therapy**—Dinkler points out that whereas some investigators have observed atrophy of the subcutaneous fat tissue after insulin therapy cases of hyperplasia of the fat tissues seem to be less frequent. He has observed a mixed form of lipodystrophy namely atrophy and hyperplasia side by side. A diabetic woman gave herself one injection of insulin daily into each thigh. In the course of this treatment there developed in the upper parts of the thighs deep depressions indicative of atrophy of the subcutaneous tissues and immediately below these depressions there appeared cushion-like areas or hyperplasia. The author points out that both forms of lipodystrophy, as well as the dystrophic may be avoided by frequent injections at the sites of injection and perhaps also at the

Atypical Onset of General Military Tuberculosis H. Schipper—p. 177

**Bacteria in Blood Stream After Tonsillectomy**—Fischer and Gottdenker maintain that it has long been recognized that after tonsillectomy old processes, such as nephritis, polyarthritis or endocarditis, may flare up again or that septicemias may develop. In order to determine whether bacteria enter the blood stream after a tonsillectomy and whether these can be considered the cause of the aforementioned disorders, they made bacteriologic studies on the blood of fifty one patients who had undergone tonsillectomy. They detected bacteria (staphylococci, streptococci or pneumococci) in the blood stream of sixteen of the patients. They observed that the bacteremia reached its peak two hours after the operation and completely disappeared again from twelve to twenty-four hours after the intervention. They conclude that this bacteremia is neither unusually rare nor to be regarded as a threatening sign.

Tests on Quantitative Irritability of Vasomotor Centers in Various Forms of Hypertension W. Kaab and F. K. Redlich—p. 455

**Subcutaneous Nodules in Chronic Arthritis and Articular Rheumatism**—Katz points out that nodal rheumatism is an occasional accompanying symptom of acute articular rheumatism. Small and large nodules develop during the articular disorder in the subcutaneous tissue, particularly at the sites at which the subcutaneous tissue is near the bone that is, where the fat tissue is slight on the forehead on the scalp along the vertebral column, on the ulna, on the tibia and on the back of the hands and feet. They frequently disappear rapidly. Histologic examination discloses that these nodules are neoplastic formations in the connective tissue. The author points out that Klinge has shown in studies on febrile rheumatism that these rheumatic granulomas may appear anywhere in the mesenchymal tissue (cardiac muscle, joints tendons and the vascular and neural connective tissue). Although there is an extensive literature on these nodules in acute articular rheumatism, little has been said about nodule formation in chronic arthritis, and it they appear they are often referred to as gout nodules. The author reports a number of cases in which chronic articular rheumatism and nodule formations were present. He believes that the chronic inflammatory irritations in the subcutaneous connective tissue which lead to nodule formation at certain sites may be caused by either the different organisms and their toxins, which produce the nonspecific articular rheumatism or by the spirochetes of yaws and syphilis. Aside from the multifactorial of the causal agents the aspect of the disorder is always the same. The author thinks that his observations are a new proof for the opinions expressed by Klinge and Weil namely that articular rheumatism is not always caused by the same virus but that from the point of view of the theory of allergy a reaction mechanism of the connective tissue is responsible. The bacterial toxins produce in the sensitized body a hyperergic reaction which in turn leads to granuloma formation the latter being perhaps further promoted by predisposition or mechanical factors (trauma).

**Tolerance Test with Sodium Benzoate for Hepatic Function**—Adlersberg and Minkebeck investigated the reliability of the sodium benzoate tolerance test for the hepatic function in normal persons in patients with various hepatic disturbances and in patients with other internal diseases. One

hour after breakfast (coffee and toast) the patient is given 59 Gm of sodium benzoate dissolved in 30 cc of water and then he drinks an additional 100 cc of water. The patient voids the bladder immediately after this and again four times at hourly intervals. Each one of the four portions of urine is examined for its hippuric acid content. The authors summarize the results of their tests: 1 In patients with disease of the hepatic parenchyma, the hippuric acid elimination is reduced. 2 The same is true of patients with mechanical closure of the bile passages, cardiac decompensation anemia cachectic conditions and so on. 3 When there are disturbances in the hepatic parenchyma it is probably the synthesis of the hippuric acid that is impaired but in the other disorders the resorption or the elimination is probably defective. So far it has been impossible to differentiate a reduced synthesis of hippuric acid from a reduced elimination and a disturbed resorption of the sodium benzoate. 4 Thus the hippuric acid test is not suited for the differentiation of an impairment of the hepatic parenchyma from other disorders of the liver, but it does indicate whether a disorder of the liver is progressing or disappearing. 5 Even if the test period is prolonged to six or twelve hours the differential diagnostic value of the test is not improved.

**Antiketogenic Action of Sorbose in Diabetes Mellitus**—Grieshaber found that, if patients with diabetes mellitus (with or without insulin treatment) are given twice or three times daily 10 or 20 Gm of sorbose, their acetone elimination can be reduced to one half or one third within a few days. Sorbose has a better antiketogenic action than corresponding amounts of levulose. In this respect its action is about like that of dextrose but its assimilability is inferior to that of several other sugars. If a part of the carbohydrates of the food (bread) is replaced by equivalent amounts of sorbose the elimination of the ketone bodies is reduced. Carbohydrate tolerance, blood sugar content and glycosuria are not impaired by the addition of sorbose to the food as is frequently the case with other carbohydrates when their addition to the diet becomes necessary on account of acidosis. The addition of sorbose permits a higher caloric diet particularly the more extensive use of fats, in diabetic patients with a tendency to acidosis. Under certain conditions it may permit a reduction or a complete cessation of the insulin medication. However, the action of equal amounts of sorbose gradually decreases and for this reason its intermittent use is advisable. Moreover, there are cases with slightly increased formation of ketone bodies which are refractory to sorbose. Sorbose can be used for sweetening purposes for the food of diabetic patients.

Fate of Cancer Cells in Lung. G. F. W. Kost—p. 291  
Carcinoma on Basis of Extensive Endometriosis. R. Hauser—p. 306

**Trichinosis and Cancer**—Schmidt-Lange states that it has been known for a long time that trichinosis and cancer may concur in human subjects. Moreover it has been proved in animal experiments that malignant tumors may be produced by some parasites (*Cysticercus fasciolaris* the larval form of *Taenia crassicoilis*). To be sure trichinellae have hitherto not been recognized as a causal factor of malignant tumors and the concurrence of trichinosis and cancer in human subjects has been designated as an accidental occurrence. However the author thinks that the observation of the simultaneous appearance of severe trichinosis and sarcoma in a white mouse indicates an etiologic relationship between the two processes, especially since the condition of the tumor indicated a time relation between the two conditions. The location of the primary tumor in an organ not involved in the trichinella infestation makes it appear likely that either the numerous young trichinellae that invaded the liver with the blood stream produced an irritation like that of a foreign body, or the waste products of disintegration and metabolism which in case of such a severe infestation enter the vital organs were the cause of the cancer formation. The author considers the trichinellae

not a cancer cause in the narrow sense of the word such as he had discussed in former studies on plant cancer and Rous sarcoma but rather one of the various factors ("polyetiology" according to Askanazy) that play a part in the etiology of the tumor cell.

**Fate of Cancer Cells in Lung**—Kost shows that three conditions may be differentiated in cancer cell embolism: 1 The inflow of the cells without a recognizable reaction. 2 The attachment of the cancer cells with fibrin precipitation and thrombus formation in which case the cells are destroyed or at least do not grow further. 3 The formation of a true metastasis, that is, the ingrowth of the carcinoma through the vascular wall and into the surrounding tissues. Once the tumor cells have reached the blood stream, they are intercepted at the nearest blood filter. The author thinks that this explains the high incidence of hepatic metastases, pointing out that primary tumors are rather frequent in the organs belonging to the portal system. The low incidence of pulmonary metastases seems unusual and this peculiar behavior of the lung has been discussed repeatedly. After reviewing some other reports, the author describes his own studies on the lungs of twelve patients with cancer. In two cases he found that the cancer cells that had been carried into the lung had formed metastases. In a group of five cases he detected neither pulmonary metastases nor cancer cells nor definite signs of a destruction of cancer cells. He considers three possible explanations for this negative result. Either no cancer cells entered the blood stream or they passed out again through the capillaries or they reached only some parts of the lung and escaped detection. In a third group of five cases the author detected carcinoma cells but no metastases. The presence of these carcinoma cells may be due to the fact that they reached the lung shortly before death and thus could not form metastases or the lung exerted an inhibiting effect on their growth. In regard to the latter possibility the author points out that some of the cancer cells were covered by thrombi and showed signs of disintegration, he discusses the causes of this disintegration.

**Urinary Retention, Intestinal Atony and Hemorrhage from Gastric Ulcer**—Melchior says that peritoneal symptoms are usually absent in cases of hemorrhage from gastrointestinal ulcers. Impairment of the intestinal peristalsis is hardly ever observed and occasionally the motility is even increased. The author reports three cases, in two of which hemorrhage from gastric ulcer was accompanied by severe symptoms in the form of urinary retention with an overextended urinary bladder and in one of which the gastric hemorrhage was accompanied by an ileus-like intestinal atony. He is unable to give a satisfactory explanation for these complications.

Brucellosis as Source of Infection. I. S. Kuritskaya—p. 33

**Rare Localizations of Diphtheritic Lesions**—Evkin and Sheynbaum report an epidemic of diphtheria principally because of unusual localizations of diphtheritic lesions. Of the ninety-one cases observed twenty-five were of the skin, fourteen of the eyes, three of the ears, thirty-four of the nose, three of the pharynx, two of the mucous membrane of the mouth and ten of the vagina. In seventy-eight the lesion was single and in thirteen combined. The lesions of the skin were of particular interest. The authors emphasize that besides the typical

ulcerative diphtheritic lesions, there were atypical forms resembling intertrigo and impetigo-like eczema, varicella-like vesicles abscesses and paronychias with a most varied localization. The atypical forms occurring in otherwise healthy children may be the source of a spread of infection. In their cases diphtheritic lesions always occurred in previously injured skin. They may appear as primary isolated lesions or in combination with diphtheria of other organs. The bacteriologic diagnosis was negative in half of their eye cases in spite of the clear cut clinical picture and positive effect from administration of the antitoxin. Diphtheritic otitis may run as an ordinary purulent otitis. Small doses of antitoxin (from 8000 to 10,000 units) were sufficient to control the skin lesions. Diphtheritic lesions of the eye required repeated large doses up to 100,000 units of the antitoxin.

Gonorrhea Treatment of Women P. J. van Putte—p. 969

**Epituberculosis**—According to de Bruin the clinical symptoms and the roentgenologic aspects of epituberculosis favor in many cases the explanation that this disorder should be considered an atelectasis. As a proof of this concept the author describes a case of recurring epituberculosis in which necropsy established the anatomopathologic diagnosis of atelectasis. At times the infiltration consists probably of specific tuberculous tissue that may finally be completely resorbed. In other cases however, the changes should be considered in part or wholly perifocal reactions of a tuberculous focus. Persistent observations and extensive anatomopathologic examinations may finally determine the relative frequency with which these three modalities of the disorder occur.

Hepato-gastrotherapy Considered in Light of Deficiency Theory of Pernicious Anemia Is It Really a Substitutional Treatment? T. Tempka—p. 567

**Method for Obtaining Pure Fibrinogen from Blood**—Kjellin and Paulsen point out that it was determined by Theorell that in the electric field the blood proteins proceed toward the anode but with various velocities. The albumins progress with greatest rapidity, the globulins somewhat more slowly and the fibrinogens still more slowly. The authors used Theorell's modification of the U-shaped tube of Michaelis. A method is described by which fibrinogen in its native form can be isolated.

**Reaction of Cancer Patients to Tuberculin**—The studies reported by Holmgren were made on 1,200 cancer patients during the years from 1913 to now. He found that from 70 to 85 per cent of the cancer patients are anergic to tuberculin. They give no reaction in response to the first subcutaneous injections of from 5 to 20 mg. of tuberculin and after a series of injections has been made in the course of several weeks they tolerate without fever subcutaneous injections of from 2,000 to 3,000 mg. of tuberculin. The author is convinced that this anergy is not produced by cachexia but by a cause as yet unknown. To intravenous injections of from 20 to 200 mg. of tuberculin the cancer patients react with chills and malaise followed by a sudden elevation of the temperature which subsides again in from twelve to twenty-four hours. The patients become habituated to the intravenous injections as to the subcutaneous injections and quickly acquire considerable tolerance. Subcutaneous as well as intravenous injections of tuberculin exert a sedative action on the cancer pains and frequently also have a favorable influence on the general condition.

**Isotonic Citrate Solution**—Hirschlaiff shows that the sodium citrate solution that is isotonic to the human blood has a concentration of from 295 to 305 per cent. It can be pre-

pared by dissolving 3 Gm. of tribasic sodium citrate in 100 Gm. of distilled water.

**Acanthosis Nigricans—Improvement After Liver Injections**—A patient who had pernicious anemia and acanthosis nigricans was treated by Strandell with intragluteal injections of a potent liver extract. Not only the pernicious anemia but also the acanthosis nigricans was improved by this treatment. Later he gave injections of liver extract to a patient who had acanthosis nigricans but no pernicious anemia and found that a considerable improvement resulted. In view of the fact that acanthosis nigricans heretofore could not be improved by internal treatment, the author considers his observations on these two patients of interest, although he concedes that a definite evaluation of this treatment would be premature. He considers it possible that there are certain relations between acanthosis nigricans and the gastrohepatic physiology.

\*Hypoproteinemia, Stasis Albuminuria and Cardiac Edema M. C. Ehrstrom—p. 59

\*Peculiar Form of Pulmonary Tuberculosis L. P. Dyggve—p. 68

**Use of Rat-Bite Fever in Treatment of Neurosyphilis**—Rothstrom says that the advantage of sodoku treatment over malaria lies in the relative ease with which patients in the large majority of cases overcome even greater sodoku infections, because of the slow rise and lytic fall of the temperature, an objection to the treatment is its long course of about one and a half months, which makes it more expensive than malaria treatment. Since malaria treatment leads to full remission in only about 40 per cent of the cases treated, recourse to another fever treatment is desirable in the cases without remission or with incomplete remission. In sodoku treatment a small number of animals is required, the rat bite infection can be interrupted at any time by arsphenamine preparations, the sodoku spirillum lacks neurotropy and the sodoku infection is dosable.

**Hypoproteinemia, Stasis Albuminuria and Cardiac Edema**—Ehrstrom discusses two personal cases of heart insufficiency and two from the literature in which a hypoproteinemia originated on the basis of stasis albuminuria and affected the development of the picture. Stasis albuminuria occurs in about half of the cases of cardiac insufficiency, but in only about 7 per cent does it exceed the theoretical threshold for the origin of hypoproteinemia by the loss of albumin through the kidneys. The percentage of stasis albuminuria is higher in the cases with hypertension than in those without. Consideration of a hypoproteinemic factor may be called for in the interpretation of cases with disproportion between edema and other symptoms of stasis. This factor may also to a certain extent affect the treatment of cardiac insufficiency.

**Peculiar Form of Pulmonary Tuberculosis**—Dyggve's patient a woman aged 22 without family history of tuberculosis, had twice had a serious, afebrile pleurisy. Laterally in the left lung roentgen examination showed a round, sharply defined shadow of about the size of a clenched fist which continued unchanged for about two years resembled a neurofibroma and moved on respiration. Operation revealed that the shadow was due to a cystlike formation. On histologic examination of excised tissue tuberculous granulation tissue containing tubercle bacilli was found. Thoracoplasty was followed by recovery.

## THE TRAINING OF MEDICAL STUDENTS IN OBSTETRICS

CLINICAL TEACHING AND PRACTICAL EXPERIENCE  
AS ESSENTIALS

GEORGE W. KOSMAK, M.D.

Editor American Journal of Obstetrics and Gynecology  
NEW YORK

"Ideally, all women should have the protection of delivery in hospitals under supervision of men trained in gynecology and obstetrics." The foregoing statement is one of the conclusions reached by Aldridge in an analysis of the end results of labor in 2,800 primiparas at the Woman's Hospital of New York, where he found that less damage resulted from so-called prophylactic methods, including outlet or low forceps with episiotomy, than with spontaneous deliveries. However, he is careful to limit his belief in the efficacy of such procedures to men adequately trained and to hospitals adequately equipped. It is doubtful whether there are enough institutional beds available even in large centers to provide the satisfactory outcome hoped for by Aldridge and thus it becomes necessary to balance the results obtained in such ideal hospitals with those of the home and of hospitals less adequately staffed and equipped than that institution.

### OPERATIVE DELIVERIES

During the last twenty years hospital confinements have increased in number to such an extent that, in most large cities, from 60 to 75 per cent of all deliveries are institutional. In this connection, however, a corresponding increased incidence of the termination of labor by operation must be noted, as shown in various reports on obstetric practice made public in recent years. These disclose without exception an unchanging and rather high mortality rate. The accompanying morbidity rate has received little or no attention. For example, Plass states that from a study of Middle West statistics he found an incidence of operative deliveries varying from 10 to 20 per cent. In his opinion this should be not more than 5 per cent. Plass's estimate impresses me as conservative in comparison with other figures. The report on maternal mortality made by the Academy of Medicine of New York City presents the results of an inquiry into sixty-seven representative local institutions in which 74.7 per cent of all the hospital deliveries occurred. Among these 24.3 per cent were operative. Approximately 348,000 live births took place during the three-year period under survey (1930-1932), of which it is estimated that over 69,000 were

terminated by operative delivery, or about 20 per cent for the entire city. It may be assumed that the remainder were spontaneous. A total of 1,300 deaths in women delivered at or after the twenty-eighth week included 729 after operative delivery, a rate of about 10.5 per thousand live births, and 571 after spontaneous delivery, with a corresponding rate of 2. If all the deaths are taken together it is found that about 46 per cent followed operative deliveries.

There are many other interesting things in this carefully prepared report. The cesarean incidence in one New York hospital rose from 2 per thousand deliveries in 1910 to 25 in the same number in 1927. It may also be noted that 3.8 per cent of all deliveries in the private pavilion were by cesarean section, as compared with 1.2 per cent in the wards. A similar distribution was noted in another institution, 4.98 per cent among private patients and 3.28 per cent among ward patients.

An investigation of similar character made by a special committee of the Philadelphia Medical Society and prepared by Dr. Philip Williams presents an equally significant picture. In a three-year period (1931-1933) there were over 68,000 hospital deliveries, with approximately 19,000 of these operative and 49,000 spontaneous, or an incidence of almost 28 per cent. An interesting side light on the question of operative deliveries is the statement that in a one-year delivery service of 142 births there were eighteen cesarean sections. In another general hospital maternity service with practically an open staff, there was an operative incidence of 50 per cent in the private floors and 4 per cent in the wards. Were patients in the latter group neglected? The final results did not bear this out.

A recent survey (1933) of the obstetric work in Louisville, Ky., showed that among 5,262 deliveries 58.75 per cent were conducted in hospitals and 41.25 per cent at home. Ten years previously the percentage of hospital deliveries was only 18 and the maternal death rate was rather low, 0.35 per cent, or 35 per 10,000 live births. In 1933 the operative deliveries including forceps, versions and cesarean sections totaled 706, or 24 per cent. It may be noted that in the private hospitals, where the "family doctors" did most of the deliveries, the operative deliveries were about twice as frequent as in the municipal hospitals, where about 46 per cent of all the institutional deliveries were conducted. The cesarean sections likewise were about double, in two the rate was over 6 per cent. The year following this report a rule was put into effect in one of the latter institutions that cesarean sections could not be done without consultation, this resulted in an almost immediate reduction in the number of cases.

Further statistics on the subject of operative deliveries could be quoted and it might be of interest to draw

comparisons with foreign institutions in respect to cesarean sections, for example. In the Dublin Rotunda in 1929-1930 the cesarean incidence was 1 to 100, at the Copenhagen Rigshospitalet during 1934 it was 1 to 184. These figures may be compared with 1 to 12 at the Boston Lying-In, 1 to 6 at Jefferson (Philadelphia) and 1 to 48 at the Chicago Lying-In Hospital. The Boston City Hospital shows an increase in cesarean sections from 26 per thousand in 1920 to 337 per thousand in 1929, other institutions report similar increases. In the New York series cesarean section was fatal in 310 cases among 793 deaths following operative deliveries—almost 20 per cent of the deaths during the three-year period from 1931 to 1934, excluding abortions and ectopic pregnancies.

The evident results from what should constitute a life-saving operation call for an inquiry into the relative frequency of cesarean section and the associated mortality. Many qualified observers believe that these results are due to ill advised widening of the indications, as well as quality, judgment and skill of the operator, together with operating in unsuitable surroundings.

The less frequent resort to cesarean section and other major operative deliveries in foreign maternity services may be explained probably in a number of ways, but one cannot help feeling that intervention is practiced on less evident indications in American institutions. This assumption cannot be regarded as otherwise than an indictment of the medical profession, and the latter must answer it. The evidence unfortunately cannot be brushed aside in the analyses of obstetric deaths that have been quoted, to which others may be added. The conclusion is reached that a reduction in maternal mortality is predicated first and foremost on competence, skill and judgment of the attendants, whether doctors, nurses or midwives. There are others, but these assume apparently a less important place.

In order to obtain a true insight into the situation, an effort was made in some of these studies to determine a preventability factor in the fatal cases by a careful scrutiny of the individual patients' records. The results are not very flattering to the medical profession. In the New York report it is claimed, for example, that the doctor must assume the burden of being at fault in more than half of the cases—in fact, as much as 65 per cent. Of course he was not the only one to be blamed—the patient herself as well as nurses, midwives and institutions all bear a share, but the doctor's seems to equal all the others combined. And why? Lack of competence, lack of judgment and carelessness are ascribed among the causes, and to these might be added lack of appreciation both on the part of the public and on the part of the medical profession of the proper conduct of childbirth. And why should there be such a lack of appreciation and how can it be overcome? I believe it is largely due to improper and insufficient training of medical students in schools and hospitals. Obstetrics should be made a major subject in the college curriculum, on a par with medicine and surgery and this can be done only by increasing the number of hours devoted to instruction and, above all, to providing practical experience.

#### EXPLANATION OF HIGH PUERPERAL MORTALITY

Palmer Findley conducted an interesting survey of obstetric teaching in 1928 in which he found that, while in most countries the time given to the teaching of surgery as compared with obstetrics is approximately

in the proportion of 2 to 1, in the United States it is in the neighborhood of  $4\frac{1}{2}$  to 1. It may be assumed that the consequences of inadequate attention to what should be made a major subject in the medical curriculum is reflected in the results of obstetric practice as they have been presented in recent years in numerous frank surveys. At any rate should one not give thought to what is self evident before one looks for more complex explanations of the relatively high puerperal mortality rates?

Therefore I have direct and cogent reasons for calling attention to the foregoing facts and figures about the increasing resort to operative deliveries in obstetric practice. For, if their possible significance in relation to the attendant puerperal mortality is borne in mind, such an admission might aid in finding a cause should it be desired to take the steps for instituting a remedy.

Success must be measured by results, in medical practice as elsewhere. If one would measure results in obstetrics by a reduction in puerperal mortality, it might call for a revision of methods and procedures which, judging from the rather high death rate associated with child bearing in this country, have not been completely satisfactory or successful. This rate, it must be noted, averages about 6 per thousand live births. Should it be accepted as irreducible?

Now, it has been found that the principal causes of death in childbirth are hemorrhage, shock, sepsis and toxemia, and for this group a preventable factor must be assumed if any degree of credit is to be given to the advances made in obstetric science and art. On what should this preventability factor be based? The answer may be found in the puerperal mortality studies of recent years, to which reference has been made. In practically all these, if the particular death was considered avoidable, the blame is fixed on the doctors in a large proportion of cases. May I repeat the reasons? Actual incompetence in the attendant, lack of judgment, lack of skill, inattention to the demands of the case, all are unhesitatingly put forward as having a direct bearing on the fatal outcome. If incompetence occupies such an important place in these accusations, it can be overcome only by the development of greater "respect on the part of the physician for the gravity of obstetric operations and educating him to a greater caution in attacking problems which are properly the field only of the highly trained obstetrician." This quoted statement brings me to the essential point of my thesis, namely, that the medical schools have not balanced in their teaching the practical with the theoretical side, or they have failed to accord to obstetrics its right and proper share in the curriculum.

#### VELD FOR PRACTICAL TRAINING

In forty-six medical schools in the United States that have been investigated recently by the American Medical Association, the number of deliveries required of each student before graduation is as follows:

- A Fifteen or more under supervision (as specified by Council on Medical Education and Hospitals), seven schools
- B From one to fourteen deliveries under supervision, twenty schools
- C One or more deliveries not complete supervision, sixteen schools
- D No deliveries required, two schools

The foregoing shows the lack of agreement and standardization in a most important teaching field and demands early correction if young physicians are to be equipped with an adequate knowledge of this essential

branch of medicine. Practical experience in deliveries with suitable safeguards can and should be provided, so that a student will be impressed duly with the significance of proper and adequate obstetric care. Attendance in the antepartum clinic and at a certain number of labors should be provided in hospitals directly associated with medical schools, or such practical training may be secured after graduation if the former was not available. At any rate, licensure to practice should include a requirement uniform throughout the country that the candidate has attended and conducted a definite number of deliveries, the number to be fixed possibly by the National Board of Medical Examiners or similar examining body.

In this connection another matter may be considered which has an important bearing on obstetric training. There are many large general hospitals in this country without maternity services. Their interns have no opportunity to acquire knowledge in delivery procedures. Moreover, many are known to maintain an attitude of aloofness toward obstetrics and thus detract from the importance of the subject as an essential element in the training of their intern staff. Objection has been made to the practice of obstetrics in a general hospital. This is quite another matter and I am not prepared to discuss the question, but I do feel that the importance of an adequate training in obstetrics by every hospital graduate is paramount. If it cannot be provided in the institution arrangements should be made to obtain it elsewhere under proper affiliations, so that every intern would be assured of this important element in his training. The American Medical Association and the American College of Surgeons might well make a concerted effort to incorporate such a requirement in the intern teaching curriculum of every general hospital. I believe that this step would do much to dignify the position of obstetrics in the minds of recent graduates in medicine.

May I be permitted to reiterate my contention that a thorough knowledge of obstetrics should be an essential in the training of every physician. If he decides to go into some other special field this need be no hindrance and if he goes into general practice he will have more opportunities for deliveries than he will for appendectomies or cholecystectomies. Therefore he must be fully prepared and, as pregnancy and labor are largely normal processes he must be thoroughly grounded in their physiology and mechanism. I sometimes feel that the designation of labor as a surgical procedure is an error. Truly it must be conducted with due regard to the principles of surgical cleanliness, but an expansion of this idea has led many students to interpret it necessarily as an operative procedure. Intervention, however frequently spells trouble especially if carried out by incompetent persons.

How can the gap be bridged between theoretical knowledge acquired by the student in his medical school and its application as executed by him in the role of a practitioner? If the graduate in medicine has failed to realize that in most pregnancies he is a guide and mentor selected to steer his patient between Scylla and Charybdis but interprets the case as essentially a surgical possibility, a continuation of those unnecessarily high mortality figures associated with obstetric practice in this country must be expected.

Obstetric science has progressed to a degree at which books of encyclopedic dimensions seem required to encompass all the knowledge which has accumulated

since that period half a century ago when a single volume textbook of moderate size was sufficient for all purposes. Most of this accumulated knowledge will never become available to the student, but the attempt to include much of it in the curriculum is apt to confuse his mind, he loses sight of the well known facts about pregnancy and labor in the maze of chemical, pathologic, serologic and other details of value in themselves but not essential to acquiring a working knowledge of obstetrics. Obstetric care must be simplified and made less complicated. The test tube and the kymograph seem to have displaced the hand, the eye and the stethoscope. Though this statement may perhaps be a mild exaggeration, the fact remains that obstetrics is being practiced largely as a surgical specialty in many places and with questionable results if we are to judge the outcome by the present mortality rates. It would appear necessary to shift this point of view and to increase clinical teaching on the patient rather than to devote more time to the microscope and the chemical laboratory.

As a result of certain tendencies manifested in some leading maternity hospitals apparently a comparatively small group of superobstetricians are being educated who cannot help being permeated with the idea that pregnancy is an abnormal process and must be treated as such. Rather a knowledge of the subject should be inculcated into the minds of the student and intern body which will make them realize their proper function as guides and supervisors rather than as operators. This requires a close contact between student and teacher and patient, a contact that is not always possible in all its aspects in a hospital alone. I believe that much of this knowledge can be obtained in home delivery service. The suggestion that this type of clinical work be extended may meet with opposition but the results speak for themselves. I believe that every medical student should conduct personally, under direct and proper supervision, at least twelve, but preferably more confinements and that a certain number of these should be in homes. This would mean naturally that such patients must be carefully studied beforehand in the antepartum clinic as to their suitability for domiciliary care, that a change of sentiment must be developed among certain population groups to have their babies at home and that safety of the mother is not sacrificed by this procedure. On the contrary, clinical opportunities of this kind will indelibly impress on the student the fact that labor is a physiologic process, that it can be conducted in simple surroundings, that routine narcosis or analgesia is not essential, that operative deliveries must present clear-cut indications and can be done only under proper auspices, and that their need can usually be predicted in advance. Services of this nature have been conducted in various places, their value and success may be measured by the low mortality and morbidity among their patients. At the old Living-In Hospital in New York, for example thousands of women were successfully delivered in their homes by students and interns under careful supervision. In Chicago there is being conducted an outdoor service in which during a two-year period from 1932 to 1934, over 6,500 women were confined at home with only twelve deaths, a rate of 0.17 per cent. Of these, nine died after transfer to a hospital for various reasons. The operative incidence was about 4 per cent, mostly forceps. The deliveries were all carried out by interns and senior medical students and under careful supervision.

In other cities similar services have been conducted which, in view of the attendant low mortality and morbidity rates, must be regarded as successful and adequate for the population groups which they serve. They have shown among other things that women who are up and about get through with their labors in a shorter time, that less operative intervention is required, that less sepsis results, probably because there are fewer contacts. In addition, the fact is made self evident to the student that the processes of labor are essentially natural processes, that he must become thoroughly familiar with their mechanism, that accidents are possible but may be largely avoided by exercising a knowledge of their prevention gained through the medium of his previous theoretical instruction. It may take time to instill into the minds of teachers of obstetrics the practical value of more direct and responsible contact between student and patient, but it is only in this manner that the resourcefulness can be cultivated which is so essential in the conduct of labor. Obstetric improvement cannot be measured by successful delivery in a series of versions, forceps or cesarean sections conducted in elaborately equipped institutions, rather it must be gaged by the results in the country at large as measured by the prevailing maternal mortality rates, and these at the present time are none too favorable.

The question might be asked, Shall we throw aside accumulated knowledge of the science of obstetrics and practice it merely as an art? There is no need for this assumption. One must remember that pregnancy is not a disease, that it usually pursues a fairly normal course, that occasionally it develops pathologic aspects, that accidents in labor are comparatively rare, that adequate antepartum care will avoid such subsequent trouble. In assuming the foregoing, does it mean that science is to be sacrificed for art? Not at all. On the contrary, theoretical and didactic teaching is essential to a proper understanding of the phenomena of pregnancy and labor, but it must not be permitted to cloud the issue. I feel that practical experience gained by actual contact with patients, preceded by properly acquired theoretical knowledge, will do much to establish a definite relationship between the art and science of obstetrics which cannot but redound to the credit of the medical profession.

22 East Ninety-Third Street

**The Floor of the Third Ventricle**—The third ventricle is a midline cavity. In cross sections of the brain it is somewhat lenticular in shape while in sagittal sections it appears more or less trapezoidal. Rostrally it is connected with the lateral ventricles by the foramen of Monro and caudally with the fourth ventricle by the aqueduct of Sylvius. In the dorso-ventral direction the rostral boundary is formed by the foramen of Monro, the anterior pillars of the fornix, anterior commissure and lamina terminalis. The floor is formed by the optic chiasm, infundibulum, tuber cinereum, corpora mamillaria posterior perforated space cerebral peduncles and tegmentum of the midbrain. Ventrodorsally the posterior boundary consists of the rostral end of the aqueduct of Sylvius, posterior commissure, pineal recess, pineal body and suprapineal recess. The roof is composed of a thin layer of epithelium stretching between the thalami (velum interpositum) which covers the parasagittal strips of choroid plexus which run throughout the length of the roof of the third ventricle. The lateral walls are formed by the medial surfaces of the thalami and the hypothalamus.—Davidoff L. M. and Duke C. G. The Demonstration of Normal Cerebral Structures by Means of Encephalography. V. The Ventricles, Interventricular Foramina and Aqueduct of Sylvius. *Bull Neurol Inst New York* 4: 91 (March) 1935.

## THE PUBLIC HEALTH ASPECT OF THE TEACHING OF OBSTETRICS

IN UNDERGRADUATE MEDICAL SCHOOLS

R. H. RILEY, M.D., DR. P.H.

Director Maryland State Department of Health  
BALTIMORE

The maternal mortality rate has decreased but little during the last twenty years. This is in spite of important advances in other branches of medicine, including medical research and public health education.

It is the general opinion that the time allotted to the teaching of obstetrics is too limited. Rowland<sup>1</sup> has shown that 50 per cent of the general practitioner's time is devoted to medicine, from 25 to 35 per cent to obstetrics and the remainder to minor surgery, gynecology and a few special cases. In all the published curriculums, obstetrics, which occupies at least 30 per cent of the general practitioner's time, is allowed only 4 per cent of the total time provided for a medical course, while surgery, which occupies less than 10 per cent of the practitioner's time, is given from 15 to 18 per cent of the hours allotted to the medical course.

Questionnaires were sent to fourteen medical schools throughout the country and replies were received from eleven,<sup>2</sup> only one required a thesis in obstetrics for graduation. In six schools the course in obstetrics was a combined course with gynecology and the exact number of hours devoted to the teaching of obstetrics could not be ascertained. Approximately 150 hours is devoted to the teaching of obstetrics in lectures and practical work in the curriculums reviewed. The clinical facilities appeared to be very limited in the majority of schools answering the questionnaire.

The information supplied by the colleges answering the questionnaire indicated that the clinical facilities in the majority of instances are limited and in some the student is not required to attend personally any definite number of confinement cases. One school required each student to attend six cases, and the highest number required was twelve. The lectures and demonstrations are supplemented by ward rounds and the student is assigned to cases, which he follows throughout labor and the puerperium. Operative procedure in obstetrics, the diagnosis of fetal position and pelvic mensuration are given in manikin courses. Lectures illustrated by motion pictures also form part of the course. The internship on obstetrics in most of the hospitals is limited to two months. However, in three hospitals from which information was obtained, the internship in obstetrics is for a full year.

From the information obtained by questionnaire and the data presented by Rowland, it is apparent that medical schools should raise their requirements in obstetrics before granting the degree of doctor of medicine to include the following prerequisites: allocation of at least as many hours to clinical obstetrics as to clinical surgery, the provision of an adequate number of hospital beds and patients to furnish the necessary clinical material, detailed instruction in antepartum and postpartum cases, supervision of the students' dispensary and hospital work by a competent obstetrician, personal deliv-

Read before the Thirty Second Annual Congress on Medical Education, Medical Licensure and Hospitals, Chicago, Feb. 17, 1936.

<sup>1</sup> Rowland J. M. H. Teaching of Obstetrics. *Bull. A. M. A.* Vol. 1, 82, 1925. Reduction of Mortality and Morbidity in Childbirth. *J. A. M. A.* 87: 2158-2159 (Dec. 23) 1926.

<sup>2</sup> Replies to questionnaires were received from the following medical schools: Vanderbilt University of Minnesota, University of Maryland, Yale University, Harvard University, Stanford University, University of Chicago, University of Michigan, Tulane University and Johns Hopkins University.

ery of at least twenty patients, and attendance on the delivery of numerous complicated cases in the hands of a master obstetrician. When one considers the emergencies encountered in the practice of obstetrics as compared with those met in other branches of medicine, the present division of time seems still less defensible.

Preventive medicine has worked wonders in reducing the mortality rate from many internal diseases. There is need for similar activity in the field of obstetrics. The development of more and still more teaching maternity hospitals for the better training of medical students, nurses and midwives in the art of obstetrics and the intelligent cooperation of the lay public and the profession in the care of the expectant mother will do for obstetrics what preventive medicine has done in the general field of medicine. However, an awakening of interest is going on in the preventive phase of obstetrics. The leaders in the field of obstetrics are stressing the need of vigilant antepartum care. It is this preventive phase of activity that gives promise of placing obstetrics more nearly alongside medicine and surgery in the onward progress of our science.

A better understanding of the needs for more intensive teaching in the public health aspect of obstetrics may be better appreciated by reference to the statistics on puerperal deaths. The puerperal death rates per thousand live births in the United States registration area show very little variation for the five year period 1930-1934. The highest rate for the period was 67 in 1930 and the lowest was 59 in 1934. In the United States registration area for the period 1930-1934 the total number of maternal deaths attributed to special causes was: abortions with septic conditions, 10,277, abortions without mention of septic condition (to include hemorrhages), 3,240, ectopic gestation, 2,926, other accidents of pregnancy (not to include hemorrhages), 523, puerperal hemorrhage, 7,085, puerperal septicemia (not specified as due to abortion), 14,741, puerperal albuminuria and eclampsia, 14,226, other toxemias of pregnancy, 2,605, and 12,041 due to other complications of childbirth. A total of 67,664 maternal deaths occurred in the five year period 1930-1934.

From the foregoing data, abortions, puerperal hemorrhage, puerperal septicemia, albuminuria, eclampsia and toxemias of pregnancy stand out as the cause of 77.1 per cent of maternal deaths during the years 1930-1934. The majority of these maternal deaths can be prevented. The medical officer of health of Newcastle suggests that the real cause of maternal mortality is the inadequate cooperation between the physician or midwife and the patient. The facts challenge the public health organizations and the medical profession to determine the reasons for this loss of life incident to childbirth and then, so far as possible, to prevent them.

If it is true that the majority of maternal deaths are preventable and that these deaths are largely due to albuminuria, eclampsia, toxemias of pregnancy and abortions, it is obvious that there rests great responsibility on our medical schools for more adequate teaching of obstetrics, including adequate preventive care. The importance of adequate antepartum care is generally recognized. It should include complete pelvic measurements, blood pressure determination, urinary analysis, complete physical examinations, Wassermann tests and appropriate arrangements for delivery.

The majority of the causes of maternal deaths have their beginning early in pregnancy and so far as the health department is concerned the most logical approach to the solution of the problem appears to be

the establishment of antepartum clinics conducted by competent obstetricians and the education of the women of the country to the necessity of consulting their family physicians early in their pregnancy, whether they are primiparas or multiparas, as the safe delivery in one pregnancy is no assurance against serious complications in a subsequent pregnancy.

The Maryland State Department of Health, through the Bureau of Child Hygiene and in cooperation with the county health officers, established antepartum clinics in 1928. The number of counties holding clinics gradually increased from one county in 1928 to eighteen counties in 1935, when 280 clinics were held throughout the year. The increase in attendance has been most encouraging—from fifteen in 1928 to 949 in 1935.

In 1934, of the 682 women attending the clinics 264 were white and 418 colored, 170 were primiparas, 504 multiparas and the data on eight are incomplete. Among this group, sixty were found with contracted pelvis, eighty-six had hypertension and seventy had syphilis. Four hundred and twenty-seven went through a normal delivery. Six deliveries were instrumental and eight cesarean sections. Five patients had a breech presentation. There were three operations and three miscarriages. Spontaneous abortion occurred twice and there was foot presentation in one case. One month after delivery, 444 mothers were investigated, of whom 436 were found well and eight ill. Of the 412 babies investigated, 398 were alive and fourteen had died.

During 1935 a total of 949 women, 341 white and 608 colored, made 2,007 visits to the antepartum clinics for examination and advice. Of the total number of visits made, 1,678 were antepartum visits and 329 postpartum visits. The attendance at the clinics has shown a marked increase and the service is apparently gaining favor with both the expectant mother and the practicing physician. In the counties in which clinics were held in 1935 a total of 980 Wassermann tests were taken, of which 16.3 per cent were positive. In the positive cases, either antisyphilitic treatment was instituted by the local health department or the patient was referred to a private physician for treatment.

The health officer of Worcester County reported in 1935 that, of Wassermann tests taken in twenty-one antepartum cases, eleven, or 52 per cent, were positive. One woman in this series gave a moderately positive reaction with no history of previous primary or secondary lesions. She had one previous pregnancy in 1933, the child born alive to die two days after birth. Her husband gave a negative Wassermann reaction and it would appear that the woman's infection was congenital and that the latency of the infection prevented her from infecting her husband but was of a serious enough nature to be fatal to her child.

In 1916, 13.5 per cent of the white women in rural Maryland were delivered by midwives and in 1934 the number of deliveries by midwives had decreased to 5.4 per cent. For the colored population in 1916 the number of women delivered by midwives was 59.9 per cent and in 1934 had decreased to only 51.2 per cent.

The maternal death rate was 50 per thousand live births for 1935 showing a slight drop from the rate of 52 for 1934. Ninety of these mothers were white women and forty-seven were colored. Accidents caused fifty-nine deaths, septicemia forty, and albuminuria and convulsions twenty-seven. It is gratifying to note that no deaths occurred among the women who attended the antepartum clinics in 1934 and but one death in 1935 among the 949 women attending the antepartum clinics.

The 1,698 deaths under 1 year of age recorded in Maryland gave an infant mortality rate of 621 per thousand live births. This was by far the lowest rate on record and 11.8 per cent lower than the rate of 704 for 1934. The rate for white infants was 517 and that for colored infants 998. Fifty-three per cent of the total infant deaths occurred under 1 month of age. Diseases of early infancy, including premature birth, injury at birth and congenital debility, caused 43 per cent of the total infant mortality. This neonatal mortality and the loss of lives through stillbirths can be controlled only by continuous care of the mothers.

To say that adequate antepartum care is necessary to good obstetric practice seems superfluous. It is safe to assert that 50 per cent of the expectant women in the counties at present come to delivery without this care. Minimum standards of antepartum care should include general physical examination with measurement of the pelvis, and a visit to the clinic or family physician at least every three weeks up to the seventh month and fortnightly thereafter, at which time observations should be made to determine the progress of pregnancy. Toxemias of pregnancy generally begin early in pregnancy and the patient should be questioned as to such symptoms as headache, bleeding, edema, constipation, presternal pain, vertigo and disturbance of vision. Early and regular examinations of the urine and determination of the blood pressure will serve as indicators as to beginning symptoms of toxemia. The hygiene of pregnancy as to diet, rest and exercise should be outlined at the first visit and frequently referred to at subsequent visits. Urinary analysis, a Wassermann test and determination of blood pressure should be routine.

The student should be taught that the most intensive antepartum care will be of little avail if the patient is infected at delivery. As the majority of cases are infected by induction from without it should be impressed on students that, in most instances, watchful waiting is better than meddling intervention. Preparation of the patient should be as painstaking as for major surgery. Rectal examination to determine the progress of labor should be thoroughly taught and vaginal examination made only in exceptional cases.

The expectant mother must be taught to seek antepartum care early. I was gratified at a recent county medical meeting to hear a country physician say that lately a large number of women had called at his office for antepartum care. The reason for the sudden increase of interest on the part of the expectant mother, I was informed, was the articles published in the local newspapers by the state department of health on antepartum care.

Much can be accomplished by a local maternal welfare committee with the county as a unit. The program of such a committee should be based on a survey of maternal facilities of the county—a survey of all maternal deaths in the county with inquiry as to all the contributing causes. As public health officials, our opportunities of reaching the undergraduate medical students are not great—our greatest opportunity and responsibility is with the physician, public health nurse and the women themselves.

In rural Maryland an effort to reach the physician has been made by lectures under the auspices of the Bureau of Child Hygiene and the extension work of the University of Maryland Medical School. These lectures have been given to groups of physicians and nurses in a series of six lectures. Interest seems to

have been aroused and the attendance has been encouraging, numbering about twenty-five in the smallest group to about seventy in the largest.

Emphasis is placed on the need of having patients report early and frequently to the physician and the need of a simple but careful record of each case. The student should be impressed with the essential requirements—a record for birth certificates, the history previous to marriage, the history of previous pregnancies and the present pregnancy, and the relative value of various facts found. The previous medical history should ascertain the history of tuberculosis, cardiac trouble, scarlet fever, rheumatism and nephritis. In the obstetric history such information as miscarriage, forceps deliveries, toxemias, hemorrhage, stillbirths, infections and cesarean section should be recorded.

An intelligent correlation of facts found will determine the value of the history to the physician. A history that records a miscarriage in the first pregnancy, followed by normal pregnancies and labors, is not of such importance as one that records a normal pregnancy followed by one or two miscarriages, and a first labor terminated by forceps and followed by subsequent spontaneous labor is common, while one or two labors terminating spontaneously, followed by forceps deliveries in subsequent labors, may have a profound significance.

In these extension courses, the value of careful physical examination is stressed: the size and shape of the uterus, measurement of the pelvis and palpation of the fetus as to presentation and position. Emphasis is placed on the need of careful advice about exercise, diet, clothing and constipation, and it is urged that the patient report headache, constipation, edema, hemorrhage and pain and return at regular intervals. The instruction by the physician to the patient in the matter of preparation for labor, emphasizing the necessity for cleanliness, is stressed. The public health or welfare nurse should have careful supervision of all her cases. More confidence is frequently placed in the instructions given by the nurse than those given by the physician. The education of the public must come through women's clubs, church societies and political groups of women.

Rowland has suggested for propaganda to the lay public the following important facts: That child-bearing in this stage of our civilization is no longer necessarily a physiologic process, pregnant women should report to their physician as early as the condition is known, careful supervision at relative short intervals is necessary to prevent many of the complications of pregnancy and childbirth, headache, edema, constipation or hemorrhage of any degree may mean trouble if not relieved, examination of urine, blood pressure, measurements and weight of the mother should be a routine procedure, careful examination, including examination of the pregnant uterus and measurements of the pelvis, are necessary, careful preparation for delivery frequently saves trouble in labor, and, finally, the physician who wants no record of the patient's history, who does not require her to visit him regularly and who does not wish to know anything about her until she is in labor is not the physician who should attend her.

Some day women will learn that relief from past experience lies in competent scientific obstetrics. That day will be hastened if we prepare students to render the service the child-bearing woman needs, to apply preventive measures promptly and to secure for the maternity case the best of professional care.

2411 North Charles Street

UNDERGRADUATE OBSTETRIC  
EDUCATIONFRED L. ADAIR, M.D.  
CHICAGO

One should keep constantly in mind the main purpose of undergraduate medical education in discussing any phase of it. The principal objective is, to my mind, the laying of the foundations for a knowledge of medicine on which subsequent structures can be built for general or special practice and for teaching or research and for public health activities. It is not to be supposed that any student can be properly qualified to enter satisfactorily on any or all of these fields at the time of graduation. It is essential that the student should be able to correlate the various special fields of medicine in terms of the individual patient. He should also learn that while he is responsible for the care of the individual he has a large responsibility to the community in carrying on his professional work. He must be imbued with the idea that medicine has to do with prophylaxis as well as cure and that prevention of disease and maintenance of health are often of greater significance than the cure of an individual patient of some illness.

The teachers of obstetrics should attempt to inculcate these ideas into the minds of their students with regard to maternity care. It is also important to convey the idea that the purpose of obstetric teaching is not to enable one to take care of the condition of pregnancy, labor and the puerperium but to care for the complete woman who is at the time pregnant in labor or in the puerperium. The fact must be stressed that the woman is important not only for herself but also because of her relationship to the community.

In considering hours for students it must be assumed that each one of them is employing full time and energy in preparation for his life work. It is not the absolute hours arbitrarily assigned to different fields of medical study that are important, it is the relative amount required for each. Our efforts should be to keep the absolutely required hours at a minimum level and to maintain a ratio between the different branches of medicine which is consistent with their relative importance to the undergraduate student of medicine. It is essential to keep constantly in mind the underlying principle that the undergraduate student must acquire the fundamental facts of the science and art of general medicine. His knowledge of prophylaxis and cure are of vital importance both to the patient and to the community.

In arranging the curriculum it is imperative to keep in mind that all branches of medicine are closely correlated and that knowledge of one increases the knowledge of another. Internal medicine contributes much information of value to the obstetrician relative to various diseases especially those of the cardiovascular renal systems and infectious diseases. Surgery contributes enormously to the fundamental knowledge of operative technique and sepsis. Pediatric information is invaluable to the obstetrician who assumes responsibilities for mother, fetus and new-born infant. Medicine, surgery and pediatrics have much more in common with one another than they have with obstetrics except for the close association of obstetrics and pediatrics so far as infant care is concerned.

It must be remembered that obstetrics presents new aspects relative to history taking and methods of physi-

cal examination as well as of terminology and a physiology and pathology that are essentially different from any of the other branches of medicine. The physiology and pathology are essentially the same for the other branches of medicine except for the variations due to age, structures involved, and so on. Of course the treatment varies, being nonoperative in pediatrics and medicine and operative in surgery.

It is therefore essential that sufficient time be allowed to the student in which to acquire knowledge of the more remote results of obstetrics which are apparent in gynecology as well as to acquire knowledge of the fundamentals. Much of the student's time in hours can be conserved if obstetrics and gynecology are taught by members of a combined department rather than by those of different departments, and the data will be better coordinated. Many of the disorders of the female genitalia are the result of childbearing, and the student should derive a better understanding of the sequence of events if the instructor traces their development from the delivery of the infant to a later period of the woman's life. This can be done best in a unified department of obstetrics and gynecology and affords better preparation for the prospective doctor to care for his female patients through their life cycle.

The advantages of such a combined department for the undergraduate student are the greater facilities that may be obtained, by the avoidance of unnecessary duplication, for the same budgetary expenditure, better correlation of factual data, and a clearer picture of the life cycle of the patient. The inspiration of the student should be greater and the instruction better because more capable men should be attracted to this combined field on account of the greater opportunities afforded for service, study and investigation. Such a stimulus and opportunity should tend to obviate mediocrity in the teaching of obstetrics.

There is not sufficient time to discuss the details of the instruction which should be imparted to the student. In general he should acquire the necessary knowledge regarding preconceptional, antepartum, delivery, postpartum and postnatal care. In short he should know the fundamentals of human reproduction from a medical point of view at least.

How is this knowledge to be imparted? It can be acquired by reading, but formal instruction should be of added value because an experienced clinician and teacher can select the essentials, stress the more important details, and clarify the obscure facts. A certain amount of formal instruction would seem to be necessary. The opportunity to see, examine and follow both normal and abnormal cases affords the very best means of instruction. It should be possible to observe patients who are ambulatory, those who are confined in the home or hospital, and those who pass through an uncomplicated or a complicated puerperium. There are many conditions which can be demonstrated clearly by pictures, both still and moving, by models and by manikins which cannot be shown well on the living subject, as too much has to be left to the imagination. It is possible to have the student practice many procedures on the manikin which one would not be justified in permitting on the living woman.

Instruction in obstetrics is fundamental and vital for the adequate care of the individual woman and for the best interest of the community. Much of the ignominy that has been heaped on obstetric practice on the score of maternal mortality could have been prevented by better educational methods in the past and by better facilities in the present. I would stress again that mor-

tality is only one criterion of results. The fact should not be lost sight of that great relief of pain has been obtained by the use of analgesics and anesthetics which do increase the risk to life both directly and indirectly even though the increased hazard is very slight. It should be recognized that longevity has probably been increased for both the mother and the infant by modern obstetric practice. It should not be forgotten that much of the disability that previously arose has been reduced. Certainly fewer genital fistulas are seen and one would hardly deny the probability that the remote results of trauma, such as genital prolapse, are less common today than they were a generation ago.

While the number of fatal cases of sepsis and of toxemia have not been materially reduced, apparently those fatalities resulting from the delivery of viable children have been curtailed and the serious sequelae in those women who have lived have been lessened.

Lastly, the blame for the high maternal mortality rate has been placed on the increased incidence of obstetric operation with apparent ignoring of the probability that not the operation per se but its improper selection and performance is responsible. Surgical procedures have increased enormously for numerous conditions which produce disability or cause discomfort but do not threaten life. The newly graduated student is not considered competent to perform these operations.

It should be emphatically stated that the delivery of ten, twelve or fifteen obstetric patients by any student does not qualify him to perform obstetric operations.

One important fact for every doctor and for every medical institution to recognize is that while a graduate and licentiate may be legally entitled to practice the science and art of medicine in all its branches he is not necessarily qualified to do so. Both he and the institutions in which he works and society must realize that such is not the case.

Undergraduate teaching in obstetrics as well as in other branches of medicine lays only the groundwork for practice. Unless the student is taught and made to realize what he can and should do as well as what he cannot and should not attempt, the education has been a failure.

Emergencies always constitute exceptions and unfortunately there is no field of medical practice in which sudden emergencies are fraught with so great dangers to two individuals so frequently.

Instruction and facilities for undergraduate obstetric education are still inadequate, but our facilities are not all being utilized for either undergraduate teaching or the training of interns.

Many schools have inadequate hours and facilities for proper obstetric teaching, especially from a clinical point of view. There are many hospitals in which maternity cases are taken care of and in these more teaching should be done, but they must conduct their maternity care on a plane high enough to give proper instruction to the students and to the interns who come under their egis. One vitally important factor for teaching in these institutions is a well trained staff which is interested in teaching proper maternity care.

Obstetric teaching of undergraduates requires adequate proportionate time, ample facilities and capable instructors. It is important to carry out this program in all schools as quickly as possible, because even after they are accomplished it will still be ten or fifteen years before the results are generally realized by the public.

5841 South Maryland Avenue

## USE OF THE OUTPATIENT DEPARTMENT IN MEDICAL EDUCATION

### NEWER POINTS OF VIEW

W. McKIM MARRIOTT, M.D.  
Dean Washington University School of Medicine  
ST. LOUIS

A properly organized and conducted outpatient department offers educational opportunities for the medical student, intern, practitioner, nurse and social worker which cannot be duplicated in the classroom, the hospital or private practice. The type of training that is offered in the outpatient department is absolutely essential for the complete education of the physician or nurse.

Great changes have taken place in medical education in the past generation. It has come to be realized that the student must be taught more than disease pictures and the underlying sciences. The physician now occupies a different place in society. The physician is no longer thought of merely as a person who is called in to minister to the acutely ill patient. The medical course has been arranged so as to equip the physician to take his place in the changing social order. Subjects have been introduced in the medical curriculum that previously were never considered. There are departments of preventive medicine, of psychobiology, of social service. The student studies more than disease; he studies man as an individual both in health and in sickness, as influenced by his environment. Preventive medicine is emphasized. There has come a greater appreciation of the importance of the psychologic approach to medical problems. This does not imply the psychiatric approach. Almost every patient presents a psychologic problem, rarely a psychiatric one. The psychology of medicine can properly be studied only in connection with the general examination of the patient, not as an isolated subject. The social aspects of medicine are now appreciated as never before. Medical economics has become a very live and pertinent subject. None of these subjects can be taught didactically in the classroom. They can be taught but imperfectly in the hospital wards. It is in the clinic that the student learns them through actual practical experience.

An outpatient department of the right type is a model institution for the care of the patient, and this implies more than the mere relief of medical symptoms—it implies complete health service. The clinic should function not only to cure the individual when he is sick but to keep him well. The modern outpatient department is very different from the older type of dispensary, which was little more than a medical "soup kitchen" from which drugs were dispensed for the relief of urgent symptoms, and where little or no effort was made to render adequate medical service by way of complete medical examination, diagnosis or treatment. The modern clinic differs also from the older type of hospital outpatient department, which was operated largely as a "feeder" for the hospital. The modern clinic attempts to keep the patient out of the hospital if it is at all possible to do so and still render adequate medical service. In the proper type of clinic the same standards of thorough examination are adhered to as

Read before the Thirty Second Annual Congress on Medical Education, Medical Licensure and Hospitals, Chicago, Feb. 18, 1936.

in the hospital. Unless an outpatient department is properly conducted, it serves no useful purpose in medical education. Indeed, attendance of a student in a poorly conducted dispensary may actually be detrimental to him in establishing bad habits of cursory examination or inadequate handling of patients.

#### ESSENTIALS OF AN OUTPATIENT DEPARTMENT

The first and most important essential of an outpatient department that is to be of value from the teaching standpoint is a competent staff. It takes a much better man to detect from the history or symptoms the premonitory evidences of disease than to diagnose serious illness after marked pathologic and physiologic changes have occurred in the body. Almost any physician may become familiar with the textbook descriptions of serious disease. There is little in the textbooks on the subject of the ambulatory patient and the early evidences of disease. That can be learned only from the most careful observation of many patients of different types. Normal physical diagnosis is spoken of, yet different individuals fall into different types and the physical signs are quite distinct. Failure to appreciate this may lead to gross misinterpretations of the conditions found. The keenest clinicians and the most accurate observers are those who should care for patients and teach in the outpatient department. In every division of the clinic there should be present daily at least one senior physician who serves as a consultant to the other members of the clinical staff and who actively participates in the teaching of students. Attendance in the outpatient department should not be below the dignity of the head of a clinical department.

The staff must have available necessary facilities for as complete examination and treatment as is possible in the case of the ambulatory patient. There should be clinical pathologic, chemical, metabolic, electrocardiographic and radiologic laboratories easily accessible and departments of physical therapy and mechanotherapy. A properly organized social service department is essential, for with many patients the social service department can supply essential information that may be the most important factor in the patient's condition and in his treatment.

Complete and accurate records filed so as to be readily accessible are as important in the outpatient department as in the hospital. It is most desirable that the outpatient record should be continuous with the hospital record for those patients who are hospitalized.

An outpatient department is to be judged by the character of the work done rather than by the size of its clientele. It is essential therefore that the clientele be strictly limited to the number of patients who may be adequately examined. For the best work an appointment system is necessary, at least in certain of the major clinics such as general medicine and pediatrics. Except in the case of obviously minor or uncomplicated conditions such as injuries, refractive errors, certain orthopedic conditions and parasitic skin diseases, every patient on first presenting himself to the clinic should receive a complete medical examination, and information as to social conditions should be obtained. The shunting of patients by a person at the admitting desk to special clinics on the basis of what the patient states to be his chief complaint all too often results in entirely inadequate examination and medical service.

When a patient applies to a clinic for treatment, it is the duty of the clinic not only to relieve the chief com-

plaint but to make a complete health appraisal and to investigate the patient's past history for any circumstances that might reveal the existence of conditions other than those which impel the patient to seek medical advice. The story of the patient's environment, his home and working conditions and his financial status may at times give information as important as a strictly medical history. The physical examination should be thorough, with special attention to the discovery of incipient disease. In very many instances there will be no definite physical signs, for the condition from which the patient suffers may not have brought about structural changes. The psychologic aspects cannot be neglected, for psychobiologic disturbance may be as incapacitating as organic disease. The patient as a whole must be considered. As aptly expressed by the late Francis W. Peabody, "A 'clinical picture' is not just a photograph of a man sick in bed, it is an impressionistic painting of the patient surrounded by his home, his work, his relations, his friends, his joys, sorrows, hopes and fears. Now, all of this background of sickness which bears so strongly on the symptomatology is liable to be lost sight of in the hospital, I say 'liable to' because it is not by any means always lost sight of, and because I believe that by making a constant and conscious effort one can almost always bring it out into its proper perspective. The difficulty is that in the hospital one gets into the habit of using the oil immersion lens instead of the low power, and focuses too intently on the center of the field."

After the complete examination of the individual, which, as already stated, means more than the detection of physical signs, he should be referred if necessary to special clinics for examination or specialized methods of treatment but should in any event report back to the original examining physician for interpretation of the results, and complete recommendations as to care and treatment. It is this original examining physician (or student) who acts in the capacity of the patient's family physician. It is his responsibility to advise the patient not only as to the relief of symptoms but as to his entire health program. This obviously may involve much more than the taking of a bottle of medicine or having his nose sprayed or receiving a course of intravenous injections. The patient should be advised not only how to get well but how to stay well. Ideally the physician should visit the patient in his home, but this unfortunately not being practical in clinic organization, the social service worker vicariously performs this function and acts to interpret the physician to the patient and the patient and his surroundings to the physician.

If the patient has to be hospitalized, the clinic physician or student should if possible continue the care or at least observation of the patient. After relief of the prominent symptoms the patient should not be "discharged." He should continue to return at intervals for periodic check-up. This is the true ideal of the health clinic for the application of the principles of preventive medicine.

#### WHAT THE STUDENT CAN LEARN

An outpatient department organized as outlined provides the ideal training ground for the medical student or physician. In the hospital wards and in the autopsy room, attention is centered on disease rather than on the patient and here disease may be studied under most favorable conditions. Through the observation of a group of cases of pneumonia, the student learns the

manifestations of the disease, its natural course, diagnostic criteria, therapeutic indications and responses to therapeutic procedures. If the patient dies, the anatomic alterations produced may be studied. What the student studies is pneumonia rather than the patient who has accommodately developed the disease. Once the patient has recovered, the student, and all too often the physician, has but little further interest in the case. In the hospital ward the student learns about disease, in the outpatient department he learns how to practice medicine. By serving the clinic patient, he learns what service his own patients who come to him later should receive. The patient who has become incapacitated or who has developed some condition that interferes with his efficiency wants to know how he can be put in good shape again and get back to his job. He also wants to know how he can keep in good condition thereafter. In the clinic the student deals with the patient as a human being, not as a "case" of disease, and it is with human beings that the physician will later have to deal. Relatively little of his practice will be concerned with the serious illnesses requiring hospitalization.

A student working in the proper type of outpatient department quickly learns the importance of the personal relationship between physician and patient. He learns that every patient likes and needs to have some one person whom he can consider as his doctor and general adviser. The student gains a fuller appreciation of the invaluable service that may be rendered by the "family physician" or "general practitioner" and will become less inclined to feel that it is only the specialist who is worth while. The student learns the importance of the complete examination of the patient and is therefore not likely to develop into that type of specialist who sees but a single region of the body separated from the remainder, the type of specialist who tends to bring specialization into disrepute. More general practitioners of the better type are needed in these days, when there is too much of a tendency for the patient to make his own diagnosis and go to whom he assumes to be the proper specialist from whom all too often he receives advice and treatment that is entirely inadequate so far as his general condition is concerned or may be actually detrimental. Every patient needs a personal family physician who will be intimately acquainted with his whole history and surroundings and who will be able to advise the patient when the services of a specialist are necessary and interpret to him the recommendations of the specialist. It is while working in the general medical clinic that the student learns to play the role of the patient's family physician. Later as he works in the special clinics, the student learns to appreciate the proper place of the specialist and the attitude of specialists of the better type toward the general care of the patient. In the clinic the student also learns the value of the health clinic and the periodic physical examination—he learns in a very practical way preventive medicine in the antepartum and well baby and dietetic clinics.

#### THE ECONOMIC ASPECT

In this day of changing social conditions the physician needs to have a clear point of view concerning medical economics. There has been so much loose talk and acrimonious discussion on the part both of uninformed physicians and of uninformed laymen on the subject of medical economics that it is very neces-

sary for the young man entering the profession to know the real facts of the case. There is no better place to obtain first hand information concerning certain phases of medical economics than in a good outpatient department. The central problem of medical economics is how adequate care of the patient may be rendered and paid for. In the outpatient department the student learns the meaning of adequate medical care. He learns what that care costs in the time and effort of the physician and the nurse. He learns something of the accessory costs of medical care, including nursing service, drugs, laboratory procedures and hospitalization. He learns the attitude of the man in the street toward the physician and how little or how much the average person appreciates the time and effort expended by the physician. He learns the attitude of the average man toward the physician's charges, and above all he learns that in any plan for medical care the physician must be the central figure to whom all other instrumentalities are merely subsidiary. It is the doctor who must be the captain of the ship, however necessary the engineers and stewards may be. Through information obtained in the clinic directly from the patient or from the social service worker, the student learns the more remote but far reaching effects of disease on the patient's whole life and outlook. He learns that the cost of illness cannot be budgeted by the individual and that serious illness in the case of the person in moderate circumstances may mean financial ruin or the acceptance of charity.

The student learns that a well organized clinic can give adequate medical care with very great economy of operation, and he cannot fail to realize that, the more the overhead costs of rendering medical service can be reduced, the easier it becomes for the public to pay its bill for health service and at the same time to render to the physician the rewards to which he is justly entitled.

#### EDUCATION OF THE COMMUNITY

The outpatient department serves to educate not only the medical student, the nurse, the general practitioner, the specialist and the social service worker but also the public. Through outpatient departments the public learns the meaning of adequate medical care, and having once learned this it will not be satisfied with less. Well organized clinics invariably raise the standards of medical practice in the community. The fear has been expressed that patients who, as the result of the financial depression, have been forced to seek medical relief in clinics will, with the return of better economic conditions, be unwilling to return to their family physicians, that is, that they will have become "clinic minded." The physician who has been rendering adequate health service to his patients need have no fear. His patients will return, for in their minds he can never be replaced by the clinic. On the other hand, the patient who has not previously received adequate service may learn for the first time that such is the case, and in this instance it is not the clinic but the physician who is to blame.

General education of the community as to the meaning of adequate medical care can in the long run have only a good effect. When the public learns that adequate medical care is worth while, the public will demand it and will be willing to pay for it. The medical profession has always been willing to render that service and has never been better prepared to do so.

500 South Kingshighway Boulevard

IS ANESTHESIA BEING NEGLECTED  
IN THE MEDICAL CURRICULUM?

RESULTS OF A SURVEY

A L SCHWARTZ, MD

CINCINNATI

I made a survey of the medical colleges of the United States in an effort to determine the hours of instruction, both theoretical and practical, given medical students during their four years of work. It was felt that such information might be enlightening in its relation to the controversy of nurse versus professional anesthesia. The questionnaire which was sent to the deans of the seventy-four accredited medical colleges of the United States, received fifty-seven replies. As seven colleges have a medical curriculum of only two years, fifty replies were available for the survey.

Is there a course in anesthesia for the students? was the first question. Forty-five affirmative and five negative answers were received. The number of hours of theoretical instruction varied from four to sixty hours (in one college), averaging 10.8 hours or, excluding the college with sixty hours, 9.3 hours. The number of hours of practical demonstration varied from none to 150 hours, the average being indeterminate. Three colleges give no practical demonstration.

Is there a department of anesthesia in, or affiliated with, your college? was the second question and received ten affirmative and forty negative replies.

If not, which department supervises instruction in anesthesia? was the third question. The surgical department supervises instruction in thirty-six and the department of pharmacology in four colleges.

In analyzing this survey it is obvious that despite the inclusion of lectures in anesthesia to the students there is a wide variation in the amount of time devoted, with an average of about ten hours given to the entire subject of anesthesia. Furthermore, it is inconceivable that in five medical colleges there is no instruction in anesthesia. With regard to practical demonstration, the extremes are even more marked. Again it is inconceivable that anesthesia is entirely neglected or given only a meager amount of time in the medical curriculum. The summation of the replies to the second question may throw some light on the reason for this neglect. In only ten of the colleges that replied are there departments of anesthesia as a distinct and separate unit. To me, this survey indicates a deplorable inadequacy of training in anesthesia for the medical students.

Why should anesthesia be ignored in the medical curriculum? Anesthesia today requires careful comprehensive training to afford the patient the maximum benefit of the advances made in anesthesia during the past fifteen years. Why should patients have excellent surgical care and doubtful care from the standpoint of anesthesia? Is it not unfortunate that Dr. Lund of the Mayo Clinic in an address to the anesthesia section, must speak of the inexperienced and occasional users of anesthetic agents?

In addition to the inadequacy of training in the medical schools, the facilities for postgraduate training are limited. In a recent issue of *THE JOURNAL* the number of hospitals approved for residency in anesthesia numbered six. The total number of approved residencies

numbered eight. Such a small number certainly indicates either a lack of interest in anesthesia which is tragic or a disregard by the medical profession of the importance of training in anesthesia. Without well established anesthetic services in the hospitals there is no incentive to the younger graduates to go into a field of medicine that requires just as distinct and well defined training as any other specialized branch of medicine.

I was astonished at the situation evident in this survey and feel that the profession as a whole should be cognizant of the sad neglect of a branch of medicine that is so widely practiced and which so rightfully belongs within the bounds of the medical profession.

It is hoped that this survey may be instrumental in stimulating a renaissance of the instruction in anesthesia in our colleges and hospitals.

19 West Eighth Street

THE LABORATORY OF PATHOLOGY  
IN THE SMALL HOSPITAL

HOWARD T KARSNER MD

Professor of Pathology Director of the Institute of Pathology  
Western Reserve University and the University Hospitals

CLEVELAND

In order to provide proper care for the patients, the smaller hospitals must offer an adequate laboratory service. If the attempt were made to provide all the special features of the laboratories of the larger hospitals, the expense would be out of proportion to the total budget for operation of the hospital. The cost per patient would be higher than in the larger institutions, for exclusive of endowments the cost of the laboratory work is borne by the patients, whether on a flat rate basis or on the basis of payments for each test. Nevertheless professional standards demand that the patient in the small hospital be given care at least equal to that provided in the larger hospital.

The features may be discussed from the point of view of physical plant and personnel. In this paper the major attention is paid to the latter. The amount of space to be allotted for the laboratory depends in certain measure on the amount and variety of work contemplated. In the life of a hospital plant the space originally assigned is usually smaller than what is ultimately required.<sup>1</sup> If the original amount of space should be too small, the cost of its enlargement may well prove to be a source of embarrassment. An estimate of the needs for a general hospital is in the neighborhood of 2,000 square feet of laboratory space for each 100 beds. If the proportion of maternity beds and bassinets is large, this figure may be somewhat high. If the medical and surgical services show a rapid turnover, the figure is low rather than high. Although the establishment of a laboratory service in a small hospital may seem amply provided for at the start with an amount of space less than that indicated, the work, when well done, usually increases rapidly in volume, and expansion of space is soon necessary. Work in a laboratory is not entirely dependent on floor

From the Institute of Pathology Western Reserve University and University Hospitals.

Read before the Thirty-Second Annual Congress on Medical Education, Medical Licensure and Hospitals, Chicago, Feb. 18, 1936.

<sup>1</sup> This may be interpreted as an adverse criticism of hospital architecture. In the long experience of the author, the criticism is justified. There are no records of too much laboratory space in the original design of a hospital and many of too little.

From the Department of Anesthesia and Gas Therapy, the Jewish Hospital.

area, but wherever possible provision should be made for about 2,500 or 3,000 square feet for the first 100 or 150 beds, to which should be added 2,000 square feet for each additional 100 beds. Inability to provide this much space should not discourage a small hospital from the inauguration of laboratory service. Nevertheless every effort should be made to avoid cramped quarters. Location is another item of importance, because light and ventilation are essential. Basements are for various utilities which do not include laboratories unless ample light and ventilation can be provided. Upper floors are far more suitable. Excellent laboratory work has been done in dark, inaccessible, cramped and poorly ventilated spaces, but precise laboratory tests have become essential to the best type of medical practice, and the physical plant should give every possible advantage to the laboratory workers. Pasteur did his early experiments in an attic and never required a palace, but when given the opportunity had a workshop with all the conveniences available at the time. The modern hospital laboratory worker is no Pasteur,<sup>2</sup> but his examinations require more exactitude than any of the earlier biologic work of that giant of science.

The equipment should provide for the more common and less complicated examinations. Thus it is necessary to make provision for the qualitative examinations of urine, blood, gastric contents and feces, as well as several of the less complex quantitative tests. If at all possible, provision should be made for the immediate chemical examination of the blood for carbon dioxide combining power, total nitrogen and sugar content. Blood typing and simpler bacteriologic tests are essential. Most hospitals with any considerable surgical service require equipment for the preparation of material for histologic examination. The autopsy service necessitates a complete equipment of instruments, table and plumbing. There are certain tests which, because of complexity, need for special apparatus and technical skill, and lack of urgency in report, may be delegated or "farmed out." These include, for example, certain blood chemical tests such as those for plasma proteins. Although often urgent, it may be necessary to delegate the various toxicologic determinations both qualitative and quantitative. Decision as to whether or not the complement fixation or other tests for syphilis shall be performed in a small hospital laboratory is often difficult. It must be decided on consideration of the training of the technician and the unit cost. It is almost certainly uneconomical to perform the Wassermann tests unless there are about 200 a week to be done. The factor of cost plays a much smaller part in the various precipitation tests for syphilis, but here the experience and training of the technician and the adequate control of antigen preparation are of the highest importance and it is certain that, unless the right technical service is available, even these tests should be delegated. It may be necessary, if animal quarters cannot be provided, to delegate hormone tests such as the Aschheim-Zondek or Friedman test. These may be urgent, as for example in suspected extra-uterine pregnancy, but, if the place to which they are assigned is not too remote, the delay may not be significant.

The personnel of the laboratory includes a director, house staff, technicians, and in some instances a record clerk.

It is common practice in some of the smaller hospitals to place the ward laboratory service in the hands of technicians. This appears to be due to a feeling on the part of the visitants that the work is better done in this way, and to a certain reluctance on the part of the house officers to perform this duty. Although in the past the first of these two reasons may have been good that time has passed. Graduates of modern medical schools have invariably been well trained in the routine examination of urine, blood, gastric contents and feces. They enter a hospital for the purpose of adding practical experience and closely supervised responsibility for patients to the groundwork provided by the medical schools. It is my considered opinion that a significant part of this postgraduate period should be practice and experience with these laboratory examinations, examinations that are the daily habit of the conscientious practitioner. The hospital that utilizes the technician for this purpose is delinquent in its duty to the house officers.<sup>3</sup> The house officers who in their first year or two of hospital training insist on having these tests performed by a technician neglect a real opportunity. They are required to make the examinations in most of the larger hospitals and should be so required in the smaller hospitals. The fact that this provision in the smaller hospitals would relieve the technician for more work of other types is only incidental and has no bearing on the educational principles involved.

The number of technicians to be employed depends on the size and character of the hospital and the volume of work required. If laboratory work is to be done at all, one technician at the least is required. It may be that the one technician can be so trained as to care for the ordinary routine of the clinical laboratory, as well as the radiologic and electrocardiographic departments. In no case, however, should the technician be so overloaded with work as to necessitate hasty examinations or be required to do things for which he or she is not fully trained and competent. The expense of adequate technical service is never an extravagance.

The most important item is the selection of a director of the laboratory. The problem of the smaller hospital is as to how the services of a well trained, experienced, competent pathologist can be obtained for this service at a cost which is not prohibitive. A small hospital may be so well endowed that it can afford a rate of pay attractive to a competent person, but unless it is large enough to provide material to occupy him and can support something in the way of a research program, the post will have no appeal to any but one who is satisfied to be a hired man.<sup>4</sup> It is possible that a hospital may be so remote from the medical center that it could not participate in a plan similar to that to be outlined, but with modern communications such an instance would be unusual. With few exceptions, it is probable that it is uneconomical for a general hospital of less than 250 or 300 beds to provide for the full time service of a competent director of laboratories. The problem, then, is as to how best to arrange for a part time director who will compare favorably with the director in the larger hospitals. It is of course possible for one person to serve several smaller hospitals. Often enough,

<sup>3</sup> The implications of this bald statement are humbly drawn to the attention of the Council on Medical Education and Hospitals.

<sup>4</sup> This is a generalization that may have exceptions in periods of economic distress.

<sup>5</sup> Pathology is a hazardous occupation even when cloistered. Thus the addition of the traffic hazard seems proportionately of little significance.

<sup>2</sup> This may underestimate the genius of some contemporaries. In the event of this remote possibility the author offers his apologies.

this means that not one of the hospitals has a large laboratory of the first class. If, however, he is connected with one high grade, amply equipped and fully manned laboratory, a satisfactory arrangement can be consummated. In this sense the laboratories of the smaller hospitals can be satellites to the sun of the larger institutions. That this arrangement is practicable is shown by experience in Cleveland and in certain other cities. In that city there are two such solar systems, the larger centered in the Institute of Pathology.<sup>6</sup> The institute, a part of Western Reserve University and its school of medicine, serves as a central laboratory for the university hospitals. The training given the assistants can thus be on a broad basis. In addition to the autopsy work and all varieties of surgical pathology, training is afforded in bacteriology, immunology, biochemistry and other routine. The institute furnishes, for part time service as laboratory directors in the smaller hospitals, men who have been given this well rounded training for three years or more after having had clinical internship. The amount of time to be given by the pathologists is settled after conferences between the hospital authorities and the director of the institute. The salary paid depends on the time required and the experience of the pathologist. Payment to the pathologist on the basis of number of examinations has been avoided so far. It is believed that if such a basis were adopted there might be some restriction on the examinations requested by the clinician, which at times might be detrimental to the best interests of the patient. For this reason the recommendation is made to the hospital that the cost of private accommodations be so adjusted that it includes the usual laboratory routine. Experience so far has shown that by this method the laboratory has not been exploited, except in a few rare instances. When this occurs, a conference between the hospital executive and the offending physician has resulted in understanding and cooperation. How far this principle may be applied to radiologic and electrocardiographic service differs with various hospitals.<sup>7</sup>

The time necessary for the work of the different hospitals varies. In one hospital, three visits a week are required. In another, the pathologist is present all of every morning. In two others, he visits every week and in still another he visits every two weeks. In the latter instances, specimens regarded as urgent in the intervals are sent to the institute.

The arrangement as it concerns the personnel of the institute varies. In one case, a senior assistant visits every week and has an assistant on the clinical staff of the hospital, not rated as a pathologist or even assistant pathologist, who "cuts in" surgical material and delivers the sections to the institute. Diagnoses are made solely by the pathologist. The weekly visits have to do principally with guidance of the technician and consultation with the staff.

Another senior assistant pursues the same general method with a hospital, which he visits every two weeks, except that in this case there is no assistant other than a highly trained experienced technician.

An intermediate assistant makes short visits three times a week to two hospitals and once a week to a third hospital.

Another intermediate assistant, somewhat junior to the one just noted, is on duty at one hospital all of every morning. For this service he is paid at a higher rate by the individual hospital than is true of the others.

It is apparent that the two senior assistants render their outside hospital service with practically no sacrifice to the work for which they are primarily employed. The first of the intermediates gives about half his time, somewhat irregularly distributed, to the university and the university hospitals, for which he is paid a small stipend. The more junior of the intermediates gives his afternoons to the university and the university hospitals. This is considered to be by far the less desirable half of the day, and his stipend is in the form of maintenance.

Although the contracts are made between individuals and hospitals, the arrangements are made with the director of the institute and in certain measure are under his control.

The hospitals so served are about 2, 6, 6, 6, 20 and 40 miles from the institute. The hospital 20 miles distant is visited once a week and the one 40 miles distant once every two weeks.

The advantages to the smaller hospitals by this arrangement are several. The director of the institute guarantees to provide a well trained and competent pathologist. This person has the backing and professional support and advice of the personnel of the institute. In case of difficulties he can immediately consult with any one of the four seniors, who have had many years of experience in pathology, bacteriology, immunology and biochemistry. The number of persons at the institute is such that in the absence of any one of the small hospitals' pathologists, either by illness or by vacation, his work can be carried on by one of the others. Thus the hospital work is covered at all times. This does not mean that always the visits to the hospitals are uninterrupted, but it does mean that diagnoses can be given at once.

The salary paid by each of the smaller hospitals is insufficient to pay a pathologist for full time service except in one instance, in which the amount would support a meager existence. This hospital, if it were not for the institute association, would be obliged to have as its pathologist a person inadequately trained for the responsibilities entailed and probably unsuited for connection with the larger institution. His chances for advancement in his field would be circumscribed by the necessity for self training and by a lack of opportunity for research. The part time given to the institute affords constant supervision in further building up of experience and training, ample consultation with older and fully competent pathologists, attendance on the weekly staff conferences, access to an excellent library, and favorable conditions for original investigation. The advantages to the institute lie in the provision of part time service of several workers who could not otherwise be held, as well as augmentation of wealth of material. Two spheres of influence are thus created, one in the university hospitals and those closely affiliated with the university, and the other in the smaller hospitals through the medium of their laboratories. It is believed that the insistence on precision, the constant interchange of views and the critical atmosphere of the institute are of educational and inspirational value in these spheres.

6 The other smaller in volume but with a hot sun and powerful gravitational force is centered in the Mount Sinai Hospital Laboratory directed by Dr. Benjamin S. Kline.

7 It is believed that the general plan here outlined is suitable also for roentgenology in the small hospital. It is difficult for the author to believe that a good roentgenologist can be at the same time a competent pathologist but he freely admits that it is almost as difficult for a good pathologist to be a competent roentgenologist. The precision of modern medicine cannot be harmonized with the combination of the two offices in one person.

The university hospitals routine in the institute is paid for by those hospitals. The director of administration of the university hospitals, by virtue of his sense of community responsibility and interhospital courtesy, has approved a plan whereby special tests, for which the smaller hospitals are not equipped, may be performed at the institute. Thus, uncommon biochemical tests, toxicologic tests, biologic tests, bacteriologic identification, immunologic studies, special stains and the like may be absorbed in the routine of the institute, without significant addition to its cost of operation. It is understood that so long as such tests are occasional the institute makes no charge. If they become frequent, a decision will have to be made as to whether the smaller hospital equips for them or pays the institute the approximate cost.

It will readily be seen that this principle provides for a complete laboratory service to the smaller hospitals. The application of the principle must vary in the separate instances with the particular needs to be met. The hospital has not available at all times the immediate service of a pathologist, but in all cases the pathologist holds himself ready to respond to emergencies and to perform such autopsies as must be done at times when he is not regularly at the hospital. The plan is adaptable to a wide variety of circumstances and furnishes laboratory service of the highest grade, suitable to the requirements of the hospital and to its purse. Its patients can be studied with thoroughness and precision. In practice over several years, the plan has been found to be satisfactory to the smaller hospitals and to the institute.

It is to be emphasized that this plan is established to provide for the smaller hospitals professional pathologists rather than to secure part time assistants for the larger central laboratory. It does not solicit part time service for the university work.<sup>8</sup> On the contrary, the centrum is the university laboratory and there the pathologist has his headquarters.

Potentially the plan has possible disadvantages. From the university point of view there is the danger that the part time assistants so provided may partly replace an instruction staff whose time and principal interest are devoted to academic work. This would undo all that has been accomplished in the building up of full time university personnel. From the small hospital point of view, the successful operation of the plan should not be permitted to interfere with the growth and expansion of the laboratory jointly with that of the hospital, so that as work and funds increase the hospital may have its own pathologist.

<sup>8</sup> This should not be interpreted as self righteousness. This department is grateful for the assistance of the pathologists of some of the larger hospitals in teaching and investigation.

**Amount of Food Required**—In general it may be said that the food requirement of a young to middle-aged man of average size without muscular work or physical exercise eating a mixed diet sufficient to meet his need approximates 2000 calories per day and that such muscular activity as is incidental to very quiet living indoors may be expected to raise this requirement to about 2200 calories per day. These estimates are for a normal man of average size weighing (without clothing) 70 kilograms or 154 pounds. Larger or smaller normal men will require more or less approximately in proportion to their weight when other conditions are uniform. Women average about four-fifths the weight of men and because of this difference in size they spend about four-fifths as much energy for like activity.—Sherman, H. C. Food and Health, New York, Macmillan Company, 1934.

## THE BLOOD IN ARTHRITIS

EDWARD F. HARTUNG, MD  
JOHN STAIGE DAVIS, MD  
OTTO STEINBROCKER, MD

AND  
MARGARET E. STRAUB  
NEW YORK

During the last three years at the arthritis clinic of the New York Post-Graduate Hospital we have made various blood studies in chronic arthritis. Most of these data have been published in full elsewhere, but a summary and correlation of the material is timely. It may be said that as yet not one of the conditions found by any method of blood examination can be said to be entirely diagnostic. The cause of arthritis is still unsettled. Nevertheless we feel that some of the results summarized here are suggestive contributions to the solution of the arthritis problem. The distinction is continually made between rheumatoid arthritis and osteoarthritis. It is generally, although not universally, conceded now that they represent two distinct disease entities.

Most of the usual blood analyses, such as the routine chemical examination of the blood, have been found normal by many investigators as well as by ourselves. These negative results are not recorded here. The sedimentation rate of the erythrocytes is likewise not

TABLE 1—Summary of Abnormal Nonfilament Counts

	Rheumatoid Arthritis			Osteoarthritis		
	Number of Patients	Percent of Abnormal	Average Count per Cent	Number of Patients	Percent of Abnormal	Average Count per Cent
Average for entire series	100	96	29.6	100	53	21.6

discussed, except in relation to the serum protein studies, because this field has been well covered elsewhere in many publications.

### FILAMENT-NONFILAMENT COUNT IN CHRONIC ARTHRITIS<sup>1</sup>

The ordinary total white cell and differential counts have been found largely normal in arthritis by many investigators. We obtained similar results in forty-six patients with rheumatoid arthritis of whom thirty-six, or 80 per cent, showed total white blood cell counts between 5,000 and 10,000 cells per cubic millimeter, while the average differential count of polymorphonuclear neutrophils was 64 per cent. Almost identical figures were obtained by us in a group with osteoarthritis. Further analysis of the blood cytology by special methods however shows abnormal changes in the leukocyte picture in arthritis.

Schilling's modification of the Arneeth count has until recently received little attention in chronic arthritis. A number of workers here and abroad are in agreement that the Schilling hemogram indicates a "shift to the left" as a characteristic of rheumatoid arthritis in at least the greater number of patients reported.

A simplification of Schilling's method, wherein the polymorphonuclear neutrophils are divided into only

This work was supported in part by a grant from the Josiah Macy Jr. Foundation.

two groups, nonfilamented and filamented, is becoming increasingly utilized and has been employed by us in the study of the leukocytes in chronic arthritis. The first group, or the nonfilamented cells, consists of the young neutrophils in which the nuclei are unsegmented or, if segmented, the nuclear parts are still joined by thick portions of nuclear material. The second group, or filamented cells, consists of those neutrophils in which a fine filament of chromatin material connects two or more segments of the nucleus, i. e., the true polymorphonuclear cells.

TABLE 2—Serum Calcium

Type of Case	Number of Cases	Mg per 100 Ce			
		Mean	Probable Error of Mean	Standard Deviation	Probable Error of Standard Deviation
Control (Greene and Boothby)	832	10.941	$\pm 0.015$	0.647	0.010
Rheumatoid arthritis	50	10.218	$\pm 0.067$	0.699	0.048
Osteo arthritis	50	9.986	$\pm 0.059$	0.616	0.042

We have found that the nonfilament count in 100 patients with rheumatoid arthritis was elevated in ninety-six patients, while in a group of 100 osteo-arthritic patients the count was above normal in fifty-three. The average nonfilament count in the rheumatoid group was 29.6 per cent, and in the osteo-arthritic patients with elevated counts the average was 21.6 per cent. The normal count is considered to be 16 per cent. Table 1 gives a summary of our results.

The high incidence of an elevated nonfilament count in rheumatoid arthritis suggests the presence of an infectious agent in this disease. The elevated nonfilament count in slightly over half of the patients with osteo-arthritis is worthy of comment. These abnormal conditions in osteo-arthritis may be due to associated rheumatoid disease or focal infection.

The filament-nonfilament count, we find, is a simple aid in differentiating rheumatoid arthritis and osteo-arthritis when within normal limits. A normal count indicates that rheumatoid arthritis is not present. An elevated count may indicate the presence of rheumatoid arthritis, mixed arthritis or osteo-arthritis with focal sepsis.

#### THE SERUM CALCIUM IN ARTHRITIS<sup>2</sup>

In rheumatoid or atrophic arthritis there is a general decalcification and rarefaction of the bones involved. This is most marked at the epiphysis, but the cortex of the shaft is involved as well. In osteo-arthritis or hypertrophic arthritis the process of decalcification is not so marked. There are characteristic cysts at the chondro-osseous junctions and a simultaneous deposition of new bone which produces exuberant at the areas denuded of cartilage, and calcified excrescences at the edges of the epiphysis. Most pathologists now consider that the fundamental and initial lesion in osteo-arthritis is an erosion of articular cartilage and that the calcified excrescences are secondary and perhaps compensatory in character.

So far, attempts to study the calcium balance in arthritis have produced negative results. Arthritis is a chronic disease and the disturbance in the calcium metabolism would probably be too small to demonstrate

conclusively in a balance experiment of a few days' duration. That there is, however, a disturbance in the calcium metabolism is indisputable.

Many attempts have been made to study serum calcium in arthritis. The technic for the determination of serum calcium is especially liable to technical error. The resulting marked variations in the results have led to confusion on this subject.

One of us together with Carl H. Greene studied fifty typical cases of rheumatoid arthritis and a like number of cases of osteo-arthritis, for the determination of the serum calcium. The Clark-Collip modification of the Kramer-Tisdall method was used. The analyses were all done in one laboratory.

The usually accepted normal range for the serum calcium is between 9 and 11 mg per hundred cubic centimeters. We used as our control group 852 cases reported by Greene and Boothby of the Mayo Clinic. Table 2 gives a summary of our results.

Thus we see that the values for the mean and the standard deviation of the serum calcium in a group of fifty cases of rheumatoid arthritis were  $10.218 \pm 0.069$  mg per hundred cubic centimeters. These values were essentially the same as those found in the control group.

The values for the mean and the standard deviation of the serum calcium in a group of fifty cases of osteo-arthritis were  $9.986 \pm 0.061$  mg per hundred cubic centimeters. The changes in the serum calcium in any individual case of osteo-arthritis are perhaps without direct clinical significance, but the trend in the group represents a statistically significant reduction in the mean calcium level. The reason for this change is not obvious. Its presence in osteo-arthritis and absence in rheumatoid arthritis are further evidences that these two conditions represent separate clinical entities.

This study of the serum calcium furnishes no evidence that the hyperactivity of the parathyroid glands is a factor in the production of arthritis.

#### THE CHOLESTEROL CONTENT OF THE PLASMA IN ARTHRITIS<sup>3</sup>

There are very few reported studies of the cholesterol metabolism in arthritis. The present investigation, carried out by Maurice Bruger and one of us, includes a study and statistical analysis of the cholesterol partition in the plasma in ninety-two cases of arthritis.

TABLE 3—Total Cholesterol Content of the Plasma

Group	Number of Observations	Arithmetic Mean Mg per 100 Ce	Standard Deviation	Probable Error of Mean	d σ D
Normal	5	194.7	29.9	12.42	6.0
Rheumatoid arthritis	3	111.2	21.5	4.60	2.27
Osteo arthritis	59	231.4	41.1	( )	5.20

Only typical cases of rheumatoid arthritis and osteo-arthritis were selected. In all the duration of the disease varied from three months to ten years. The blood specimens were obtained by venipuncture usually after breakfast. Free and ester cholesterol were determined by the Bloor-Knudsen method.

The plasma cholesterol in subjects with arthritis were compared with cholesterol studied in thirty-three normal subjects, all determinations being carried out under identical conditions in the same laboratory. Table 3 shows the results in thirty-three cases of rheumatoid arthritis and fifty-nine cases of osteo-arthritis, together with thirty-three normal subjects.

<sup>2</sup> Hartung, E. F. and Greene, C. H. The Serum Calcium in Arthritis. *J. Lab. & Clin. Med.* 20: 929 (June) 1935.

<sup>3</sup> Hartung, F. I. and Bruger, Maurice. The Cholesterol Content of the Plasma in Arthritis. *J. Lab. & Clin. Med.* 20: 675 (April) 1935.

In the rheumatoid group the average age was 39 years, 63 per cent of the patients were females. The mean total cholesterol was  $175.2 \pm 39.5$  mg per hundred cubic centimeters of plasma. In the osteo-arthritis group the average age was 51 years, 90 per cent of the patients were females. The mean total cholesterol was  $235.4 \pm 45$  mg per hundred cubic centimeters of plasma.

Average	7.02	4.42	2.60	1.71	0.3	1.32	0.4	0.9	30

meters of plasma. The cholesterol esters in both groups showed a normal relation to the total cholesterol.

These results show that the plasma cholesterol tends to be low in rheumatoid arthritis and high in osteo-arthritis. That these results, especially those obtained in the osteo-arthritis group, are really significant is evident from the statistical analysis, the difference between the means of the normal group and the rheumatoid group divided by the standard error of the difference of these means gives a value of 2.27. This variation from normal is suggestive but not definite. The same calculations applied to the normal and the osteo-arthritis group show a figure of 5.20, indicating a significant variation from normal.

The observations recorded in this study that patients with rheumatoid arthritis tend to show a low blood cholesterol support the infectious theory of its etiology, since other acute infections are accompanied by a hypocholesterolemia. The tendency to an elevated blood cholesterol in osteo-arthritis, on the other hand, suggests the degenerative origin of this disease, since other degenerative diseases are usually accompanied by hypercholesterolemia.

Two explanations for the latter finding may be suggested: first, that patients with osteo-arthritis are obese, second, that they fall in an older age group. It has been shown however, by Bruger and Poindexter<sup>4</sup> that uncomplicated obesity is associated with a normal plasma cholesterol. Also there are few studies in the literature which point to an increased blood cholesterol in the aged. Bruger is of the opinion that the factor of age alone in no way influences the level of the blood cholesterol.

#### PROTEIN STUDIES IN RHEUMATOID ARTHRITIS AND OSTEO-ARTHRITIS

Since the reawakening of interest in the sedimentation rate by Robin Fareus in 1918, there has been an immense amount of clinical and laboratory investigation concerning the chemical changes in the blood which are responsible for this phenomenon. Boots and

Dawson<sup>6</sup> first called attention to the difference in sedimentation rate in rheumatoid arthritis as opposed to that in osteo-arthritis. Snapper<sup>7</sup> showed that the power of the red cells to settle at various rates in different diseases was dependent on three factors, i. e., cell volumes, plasma fibrinogen and plasma globulin. It was in order to determine just how these changes take place that this work was undertaken.

The total plasma protein, albumin, globulin, fibrinogen, globulin fraction pseudo I and II and euglobulin and sedimentation rate have been determined on numerous occasions on seventy-nine subjects. The analyses presented here cover only the determinations done on fourteen patients with osteo-arthritis and on sixteen with severe rheumatoid arthritis. The chemical analyses were done by Dr J. P. Chandler in the department of physiology of the Cornell University Medical College. The method of Howe was used. In table 4 are given the results obtained in the blood studies of fourteen cases of osteo-arthritis. These figures approximate the average normal.

In table 5 are given the results obtained in sixteen cases of severe rheumatoid arthritis. From the study of these tables it can be seen that there is a rise in the globulin fraction and a fall in the albumin fraction in rheumatoid arthritis. The greatest change takes place in the euglobulin. There is very little, if any, change in the protein fraction of those ill with osteo-arthritis. There is usually a rise in the fibrinogen in rheumatoid arthritis but the rise is not as great as that in the globulin. The fibrinogen content of those ill with osteo-arthritis sometimes rises, and this is usually the cause for the rapid sedimentation rate that is occasionally seen in those ill with this type.

Since the changes found in rheumatoid arthritis are characteristic of infection in general, this study gives further evidence indicating that rheumatoid arthritis is an infectious disease while osteo-arthritis is not.

TABLE 5—Serum Protein Determinations in Severe Rheumatoid Arthritis

#### AGGLUTININS AND PRECIPITINS IN ARTHRITIS<sup>8</sup>

During the past five years there has been a great deal of interest in the presence or absence of streptococcus agglutinins in the serums of arthritis subjects, especially those suffering with what is commonly called rheumatoid arthritis. The presence of agglutinins for various strains of streptococci is thought by some

workers to be pathognomonic of this form of arthritis. From these workers we are led to conclude that rheumatoid arthritis serums show a high titer of agglutination with certain strains of streptococci, whereas serums from other disease conditions and from normal persons fail to show as high a titer. If this were true, the agglutination test would be a valuable diagnostic aid and

these observations would lend support to the theory that streptococci are the etiologic agents in rheumatoid arthritis.

In the appended summary (table 6) of our own observations in this regard we selected three groups: (1) rheumatoid arthritis patients, (2) osteo-arthritis patients and (3) normal controls. The strains used as antigens were all streptococci, the great mass of investigation since the beginning of the century pointing toward the streptococcus as the important etiologic factor. The strains used include organisms isolated by various workers from rheumatoid arthritis and acute rheumatic fever, and from septicemia and other infected sources.

A diffuse growth of streptococci suitable for agglutination tests was obtained. Serum dilutions were made in 0.5 per cent sodium phosphate broth and 0.5 cc of antigen was added to each dilution making the total volume 1 cc in each tube. They were shaken incubated at 56 C for two hours and placed in the icebox over night.

If one considers that agglutinations in titers of 1:160 and above are significant, it is seen that rheumatoid arthritis serums agglutinate strains AB<sub>13</sub> in 36 per cent, NY<sub>2</sub> in 30 per cent, and C<sub>17</sub> in 24 per cent of the cases in this range of dilution. These are all hemolytic organisms. Using the organisms of cases from fatal septicemias both *Streptococcus hemolyticus* and *Streptococcus viridans* we obtained agglutinations only in very low titers. In osteo-arthritis serums there was practically no agglutination in any dilution of serum with the hemolytic streptococci. In the normal

subjects, with the hemolytic strains, AB<sub>13</sub> gave agglutinations at 1:160 and above only in 10 per cent of the cases.

We conclude, therefore, that a greater percentage of the serums from patients with rheumatoid arthritis showed agglutinins for streptococci in high titers than from patients with osteo-arthritis or from normal subjects. The streptococci most frequently agglutinated by rheumatoid arthritis serums were of the hemolytic type, *Streptococcus viridans* being less frequently agglutinated. The agglutinins found in the serums of rheumatoid arthritis patients were not strain specific, more than one strain of hemolytic streptococcus being agglutinated in comparable percentages. Hemolytic streptococci known to have caused death were not as frequently agglutinated as hemolytic strains of a less virulent nature.

Lancefield<sup>9</sup> found that hydrochloric acid extracts of *Streptococcus haemolyticus*, as prepared by a modification of the Porges method, contain group-specific as well as type-specific substances. In our precipitin studies extracts of NY<sub>2</sub>, a hemolytic streptococcus, were used as antigens. The hydrochloric acid extract contained principally the group-specific carbohydrate as well as the type-specific protein M. This hydrochloric acid extract was further processed by alcoholic precipitation with sodium acetate, to eliminate all but the type specific protein M. Both these extracts were used as antigens in parallel tests and gave nearly identical results.

Parallel agglutinin and precipitin reactions were then run on the same serums. Table 7 gives our results in summary. Here again only the rheumatoid arthritis serums contained agglutinins and precipitins in significant titers. It is seen that the results of agglutinin and precipitin tests are practically identical. The trend of this work tends to show that rheumatoid arthritis serums show a higher titer of agglutinins and precipitins with certain strains of streptococci than the serums from patients with other disease conditions and

TABLE 7—*Streptococcus Agglutinations and Precipitin Reactions in the Serum of Patients with Arthritis and of Normal Subjects*

§ A serum was considered positive when a marked precipitation occurred in any dilution.

from normal subjects. This finding lends support to the theory that hemolytic streptococci are the etiologic agents in rheumatoid arthritis.

#### SUMMARY

Rheumatoid arthritis is now generally accepted as a disease of bacterial origin. Until recently this opinion has been based mainly on clinical impression. Many of the observations here summarized, however, add laboratory data to support this assumption. The ele-

Ulcer J 4 M A 99 1576 (Nov 5) 1932

operative procedure was carried out in our laboratory several hundred times in various investigations on peptic ulcer, and ulcer developed in about 95 per cent of the experiments

These results have been confirmed by Ivy and Fauley,<sup>22</sup> Morton,<sup>23</sup> Ravdin<sup>24</sup> and Weiss<sup>25</sup>

Weiss and Aron<sup>26</sup> in reporting their results expressed their opinion that the absence of duodenal juice affects especially the digestion of proteins. The proteins arrive in the jejunum as gross polypeptides after the albuminoid molecule has been liberated by the gastric juice but cannot be broken down any further to the assimilable components, the amino acids, because the jejunal secretion is deprived of the pancreatic trypsinogen, which is indispensable to this process. Histidine is thus lacking. They claim that it is one of the four amino acids which cannot be synthesized by the organism (cystine, lysine and tryptophan, they state, are the other three amino acids)

On the basis of these assumptions, Weiss and Aron repeated the experiments with daily subcutaneous injections of histidine-tryptophan mixture. While the two untreated controls died, the four dogs receiving such injections daily, although showing effects of denutrition, remained happy and sprightly. There was no blood in the feces. Autopsy on two of the four treated dogs after five weeks, on one after six weeks and on one after ten weeks revealed that the mucous membrane was normal. No ulcers were found.

Later Weiss and Aron<sup>27</sup> repeated the experiments after daily injections of lysine, tryptophan and histidine. Cystine, the fourth amino acid the organism is unable to synthesize from its own resources, was too difficult to inject. Injections of tryptophan or lysine did not change the evolution of ulcer. Injections of tryptophan and histidine combined or histidine alone did. The dogs became anemic and emaciated but remained in good spirits until they were killed, after a maximal survival permitted for the appearance of ulcerous lesions (five to six weeks<sup>27</sup>). Blood never appeared in the feces. Autopsies did not reveal ulcers.

#### CLINICAL REPORTS ON USE OF HISTIDINE PREPARATIONS

Weiss and Aron<sup>27</sup> as a result of the foregoing experiments concluded that under the influence of histidine-tryptophan the gastroduodenal mucosa resists the corrosive effects of the gastric juice. They then started treatment of ulcer patients with histidine-tryptophan, reporting favorable results in twelve patients. The therapy consisted in a daily injection of histidine-tryptophan mixture for three weeks. The doses varied between 1 and 5 cc for each injection, the solution consisting of 2 per cent histidine and 4 per cent tryptophan. During this time the patients were up and around, some even continuing their occupations and avocations. All previously used regimens, diets or medications were discontinued. The results in the twelve patients treated were as follows. The general condition improved and all symptoms disappeared. Pain subsided, usually after the fourth to the sixth

injection. The body weight increased at a rate of between 4 and 17 pounds (1.8 to 7.7 Kg) a week. The gastric hyperacidity diminished and finally became normal, and hemorrhages, if present, stopped. The direct and indirect roentgenologic signs, as niche or spasm, also disappeared.

The therapeutic action of tryptophan and histidine was studied separately by Aron<sup>28</sup>. Injections of histidine alone had a very favorable effect on the clinical evolution of the ulcer, which retrogressed rapidly, while at the same time pains disappeared.

Following the publications mentioned, numerous reports appeared in the foreign literature on the histidine hydrochloride (LaRostidin-Hoffman LaRoche) treatment of peptic ulcer. Blum,<sup>29</sup> Bogendorfer,<sup>30</sup> Spencker<sup>31</sup> and Hessel<sup>32</sup> report that "all" their patients became symptom free after several injections of histidine. These authors reported from six to thirty cases each. They did not restrict their patients' diet nor did they prescribe alkalis.

Deloyers<sup>33</sup> reports that in two of his ten cases the treatment was ineffective. Stolz and Weiss<sup>34</sup> stated that only three of their thirty-nine patients did not respond to treatment. Winter<sup>35</sup> reports unsuccessful results in only one of his twenty-three patients.

Weiss<sup>36</sup> in his latest report states that during the last year and a half ninety-one of his ulcer patients have been successfully treated with histidine. He further points out that during the period of treatment, and in the months following, his patients were on a full diet and received no other medication. The author finally points out that success with histidine should not be expected in ulcer cases with pyloric stenosis. He urges caution in hemorrhagic cases, advising that such medication should not be applied until bleeding has stopped.

The first report in the English language on histidine is from Ernst Bulmer<sup>37</sup> giving a preliminary report on a series of fifty-two unselected peptic ulcer cases (thirty-five gastric, seventeen duodenal). His results were as follows: "(a) 58% of symptomatic cures with disappearance of the abnormal x-ray findings, (b) 19% of symptomatic cures with persistence of some radiological abnormality, (c) 23% of failures. In a follow-up (time not stated), three patients relapsed, and one of the apparent failures improved. The patients having gastric ulcers seemed more amenable than those having duodenal ulcers, and those with a shorter history tended to react more favorably than those with a longer history.

Volini and McLaughlin,<sup>38</sup> the first American observers, report on twenty-one patients treated with histidine. Their preliminary report is concerned principally with a study of the fasting and the stimulated gastric secre-

tions, reporting a decrease in amount and degree of free and total acids. Both, however, tend to increase toward the latter part of treatment and when it is discontinued. Though they state that the various clinical features and phases will be discussed in a later paper, they nevertheless add that, "in all" their patients, symptomatic relief was obtained very quickly. No other medication than histidine was allowed. All the patients smoked and were encouraged to continue doing so. The diet was an average American diet, tending to contain an excessive amount of roughage. Their patients were allowed coffee, tea, candy and even nuts.

Manginelli<sup>39</sup> treated fifty-two patients with gastroduodenal ulcers, gastritis and gastric neuroses with histidine. The injections were made intramuscularly, although the intravenous route was also found satisfactory. In gastroduodenal ulcers, he states that the rapid analgesic effect of histidine was striking.

Smith<sup>40</sup> reports on twelve patients treated with histidine. All his patients were roentgenologically proved to have ulcer of the lesser curvature. Ordinary diet was permitted without restriction. All his patients became symptom free. A striking feature, he states, was the rapidity with which the general nutrition of the patient improved. In every case there was a substantial gain in weight. In cases in which there had been gastric retention due to pylorospasm, the emptying time improved.

In summary, then, many foreign writers report favorable results with a high percentage of successful immediate responses, from using histidine in the treatment of peptic ulcer. Not a few report that "all" their ulcer patients became symptom free with this method of treatment. I have not been able to find in any publication an analysis of the remote results (long follow up) of histidine treated patients.

#### AUTHOR'S STUDIES

In order to evaluate clinically any new therapeutic measures for peptic ulcer, certain criteria must be considered:

1 Does the method under consideration produce a higher percentage of remissions in unselected groups of ulcer patients than does the diet-alkali regimen?

2 What percentage of patients not responding to the standard diet-alkali regimen become symptom free when the new method is instituted?

3 Does the new treatment permit patients to tolerate a maintenance diet sooner than the standard treatment?

4 Does the new method prolong the symptom-free interval or prevent recurrence?

5 Does the new method have any effect on gastric acidity?

6 What effect does the new method have on the ulcer deformity as seen by x-rays?

7 Does the new method of treatment produce reactions or untoward effects?

With these criteria in mind, I have observed a series of sixty-seven consecutive ulcer patients. Table 1 shows the location of ulcer and the duration of symptoms. It will be noted that 83.6 per cent of the total number of patients had had ulcer symptoms five years or longer. Of the patients treated with histidine, 90 per cent had had the ulcer syndrome five years or longer. All were roentgenologically proved ulcers. Fifty-six (83.6 per cent) of the patients each had several previous ambulatory standard treatments, thirty-nine (58.2 per cent) had had one or more previous

rigid bed-rest Sippy management, fifteen (22.4 per cent) had had appendectomies with the hope that the ulcer would later respond to medical management, thirteen (19.4 per cent) had had previous ulcer hemorrhages, six (9 per cent) had had gastro-enterostomy, three had had perforations, one had had his gastro-enterostomy undone, and another had had a gastro-enterostomy, later a resection of the stomach for

recurrence, and finally a partial gastrectomy (Devine operation). All these, however, returned later with recurrence of ulcer symptoms.

#### METHOD OF TREATMENT

When these patients presented themselves for treatment, they were asked whether they could report for daily injections of histidine. If they could, twenty-four injections of histidine were given them in twenty-four consecutive days (twenty-three patients were thus treated). If they could not, they were started on the diet-alkali regimen (forty-six patients so treated). Those not responding to the diet-alkali treatment were then given daily injections of histidine (seventeen patients), those not responding to histidine were then started on the diet-alkali regimen (seven patients). There were thus fifty-three patients treated with diet-alkali and forty patients treated with histidine.

The diet used in the diet-alkali regimen was as follows: for patients at rest in bed, hourly feedings of milk and cream plus Sippy powders 1 and 2 with gradual increase by addition of eggs, cereals, and so on (diet 1, original Sippy diet). Ambulatory patients were started on milk, cream, soft boiled or poached eggs, strained cereals, creamed soups, custards, cereal puddings, toast and butter, divided into six feedings a day (diet 2). If, at the end of about ten days, these patients continued to be symptom free, pureed vegetables and fruits were added and the meals were divided into three a day with small feedings between meals (diet 3). Scraped beef, minced chicken and flaked whitefish were added to their diets (diet 4) from six to eight weeks after the beginning of dietetic treatment. Sippy powder 2 was always prescribed, but Sippy powder 1, liquid petrolatum, hot abdominal stupes, gastric lavages and antispasmodics were given only when indicated.

Patients starting on histidine injections were advised to continue with the same diet they had prior to the administration of histidine. Most of the patients treated with histidine were on a diet similar to diet 3 at the time they reported for treatment. After they had become symptom free they were told that they might increase their food as they pleased. No alkalis

<sup>39</sup> Manginelli, L. Histidine in Gastric Therapeutics. Arch. d. mal. digest. 25: 460 (May) 1935.

<sup>40</sup> Smith, D. The Histidine Treatment of Peptic Ulcer of the Lesser Curvature with a Note on Twelve Cases. Brit. M. J. 2: 154-159 (July 27) 1935.

were given them. These patients were not necessarily seen by me daily, as the injections were given by a nurse.

The forty patients treated with histidine were given a total of 869 injections: thirty-two patients each received twenty-four consecutive daily injections, four received from twelve to twenty-one, and four received from six to eleven injections.

Eleven of the fifty-three patients treated with the diet-alkali regimen were observed in a hospital, the remaining forty-two were treated ambulant. Of the forty patients treated with histidine, fourteen were observed in a hospital<sup>41</sup> and twenty-six were treated ambulant.

#### RESULTS OF TREATMENT

Results of treatment are discussed in accordance with the criteria that have been mentioned.

Table 2 shows the immediate results with histidine treatment. Table 3 shows the immediate results with the diet-alkali regimen. It will be noted that the percentage of remissions and percentage of moderate improvement are practically the same for the two treated groups. For the histidine series, 55 per cent of remissions and 20 per cent of moderate improvement (a total of 75 per cent of favorable responses), for the diet-alkali series, 51 per cent of remissions and 20.7 per cent of moderate improvement (a total of 71.7 per cent of favorable responses).

Claim is made that twenty-four consecutive daily injections of histidine are essential to produce maximum clinical improvement. An analysis of the twenty-two patients who developed remissions on histidine treatment shows that five patients became symptom free at the end of the first injection, six at the end of the second, four at the end of the third, three at the end of the fourth, two at the end of the fifth, one at the end of the eighth, and only one after twenty-one injections. The sudden disappearance of all discomfort in eleven of the patients after one or two injections was very striking and impressive. However, fourteen

TABLE 2—Immediate Results with Histidine Treatment

	Unselected Histidine Patients		Histidine After Diet Alkali Regimen Did Not Result in Remission		Total Histidine Patients	
	Number	Per Cent	Number	Per Cent	Number	Per Cent

Moderate improvement	5	21.7	3	17.6	8	20.0
Remission	13	56.5	9	52.9	22	55.0
Moderate improvement + remission	18	78.2	12	70.6	30	75.0

patients each received twenty-four consecutive daily injections and were either only moderately improved or received no benefit from the treatments. Moreover, ten patients who returned within three months after treatment with recurrences of ulcer symptoms (see item 4) were among those who received twenty-four consecutive daily injections. One of the two patients who returned with recurrence of symptoms within four to five months after treatment received only ten injections.

<sup>41</sup> Ten patients were observed in Receiving Hospital, Detroit and four patients in William J. Seymour Hospital, Elmhurst, N. Y. I did not personally observe two of the Receiving Hospital patients and the four treated in the William J. Seymour Hospital. They were however observed by the resident physicians of the two institutions. Accurate records are available.

It is therefore apparent that twenty-four consecutive daily injections are not essential either to produce a remission or to prolong the symptom-free period. If five or six (at the most eight) consecutive daily histidine injections do not cause complete disappearance of all ulcer discomforts, the hope of producing a remission or prolonging a symptom-free interval by further histidine treatment is negligible, based on this small series of patients.

TABLE 3—Immediate Results with Diet-Alkali Treatment

The condition of three patients was aggravated during histidine treatments. A brief history follows for each of the three patients.

CASE 1—W. S., a man, aged 65, had an ulcer history extending over twenty-two years. Gastro-enterostomy and appendectomy were performed in 1915. Bed-rest treatment was given in 1920. Several ambulatory modified Sippy treatments were given from 1930 to 1935. The patient was admitted to the hospital March 25, 1935, when rigid Sippy management was started, moderate improvement occurred but continued distress. Eleven histidine injections were then given, but after the eighth injection the patient began experiencing severe epigastric pain suggestive of penetration. Hourly milk and cream with alkalis were then resumed, histidine was continued. The symptoms did not subside. Operation showed a jejunal ulcer about 1 cm. in diameter, of the perforating type, on the mesenteric side of the jejunum just below the gastro-enterostomy. There were also adhesions. A partial resection of the jejunum to include the ulcer was done. Microscopic study did not show a malignant condition. The patient was symptom free for six weeks following the operation, when he returned with recurrence of symptoms.

CASE 2—L. R., a man, aged 60, had an ulcer history of six years' duration, during which time he had several ambulatory ulcer managements. He was admitted to the hospital May 10, 1934, with ulcer symptoms. Rigid ulcer management with hourly milk and cream and alkalis was started on admission and continued with only moderate improvement of symptoms. Roentgen examination showed a penetrating deformity in the lesser curvature of the stomach with 50 per cent retention in twenty-four hours. Twenty-four daily consecutive histidine injections were given, with no change in symptoms. A second roentgen examination after histidine showed a perforating ulcer four times the size seen after the first roentgen examination. The patient died shortly afterward. Autopsy showed his liver to be adherent to the stomach along the lesser curvature. A large crater-like ulcer with rounded indurated edges 8 cm. in diameter was found along the lesser curvature of the stomach, and a small perforation was found in the floor of the ulcer into the lesser peritoneal cavity. Microscopic study did not show malignancy.

CASE 3—M. M., a woman, aged 62, had an ulcer history of ten years' duration, during which time she had several ambulatory managements resulting in remissions but followed by recurrences. She was admitted into the hospital with an ulcer hemorrhage (hematemesis and melena). Histidine was started the day of admission and continued until twenty-five daily injections were given. During the first two days the patient was given ice chips and morphine but no food by mouth, a direct transfusion of 400 cc. of blood was given her on the second hospital day. On the third day hourly feedings of milk

and cream with alkalis were started. The patient responded nicely to this management, with disappearance of occult blood in the stools. On the ninth day, with the hope that, because of the histidine, she could tolerate a maintenance diet, her diet was changed to three meals a day and increased to the hospital "soft low residue diet." On the next day tarry stools developed (4 plus occult blood). The usual Sippy regimen was instituted, with successful results.

2 Table 2 shows that seventeen patients were treated with histidine after the diet-alkali regimen had resulted in either moderate or no response. It will be noted that nine of the seventeen patients so treated became symptom free and an additional three moderately improved, a total of 70.6 per cent of favorable responses. Though one cannot draw definite conclusions from the results obtained in these seventeen patients, nevertheless it is important to note that by histidine approximately 50 per cent of those cases showing no remission with diet-alkali treatment have been made symptom free and an additional 20 per cent moderately improved. However, the same holds true for the diet-alkali regimen when it is instituted after

TABLE 4—Follow-Up Results After Treatment

\* This patient became symptom free after the first injection of histidine. On the day of the fourteenth injection he developed a mild sore throat. On the day of the twenty-first injection he developed weakness and a mild cough. On the day of the twenty-fourth injection he was hospitalized. There was a questionable pneumonic process in the right lower lobe with an atypical blood picture. One week later a tender mass was noted in the soft tissue over the region of the ninth rib in the anterior axillary line. The hematologic and external puncture diagnosis was acute myelogenous leukemia which was confirmed two months later at postmortem examination. During the two months of his life following the histidine injections he was symptom free so far as the ulcer was concerned. There is no evidence that any coagulation exists between injections of histidine and the development of myelogenous leukemia.

histidine results in no remission three of the six patients so treated became symptom free and two moderately improved. This is important.

3 It is claimed by many authors that patients treated with histidine are able to tolerate a maintenance diet even during the early stage of treatment. That this is not borne out by my series of patients is evident from the fact that eight of the forty histidine-treated patients were only moderately improved seven were not improved and in three the condition was aggravated by treatment—a total of eighteen (45 per cent) in whom the diet could and should not be increased. Only twenty-two (55 per cent) of the patients became symptom free. Twenty of the twenty-two rapidly increased their diet so that at the end of four weeks they were on a full diet with three meals a day. The immediate response to histidine in these twenty patients was excellent.

4 A follow up of twenty patients who developed remission in symptoms after histidine treatment (table 4) showed that recurrences of symptoms appeared in

85 per cent of the patients within six months after histidine injections six within one month, five within one to two months, two within two to three months, two within four to five months, and two within five to six months after treatment. Similar follow up of twenty-nine patients on diet-alkali management showed only 31 per cent with recurrence of symptoms within the same period of time four within one month, two within one to two months, one within three to four months and one within four to five months after onset of dietetic treatment. This speaks unfavorably for the lasting benefit to be obtained from the use of histidine in ulcer therapy, as compared with the diet-alkali regimen.

It is possible that with the histidine treatment the short duration of remissions and the high percentage of recurrence resulted because of rapid increase in diet. As stated before twenty of the twenty-two patients who showed remission with histidine were on practically full diets four weeks after beginning treatment. The patients on diet-alkali management were schooled in the essential dietetics of their treatment, those treated with histidine were not so educated, had a more liberal diet and suffered early recurrences.

Patients not responding to histidine were changed to the diet-alkali regimen and vice versa (tables 2 and 3 show the immediate results). Four patients were not improved after both diet-alkali and histidine treatment. They were then again placed on diet-alkali management. One became symptom free. Two were moderately improved. One of the patients in the diet-alkali series did not show improvement until gastric lavage was instituted. Another improved when milk was withdrawn from his diet when skin tests proved him allergic to milk. By changing from one method of treatment to another and trying all means at hand to "tire the ulcer out" I was able to produce remissions in forty-nine (73.5 per cent) patients and moderate improvement in nine (13.4 per cent) patients, a total of fifty-eight, or 86.5 per cent, favorable responses. The nine patients not responding to medical management (diet-alkali regimen, histidine or both) had the following complications: two, mild hyperthyroidism, two, myocarditis, one, arteriosclerosis, one, perforation (death), one, high grade retention, one, penetrating jejunal ulcer, and one, chronic appendicitis and chronic cholecystitis. The latter three were subsequently operated on.

5 Effect of Histidine Treatment on Gastric Acidity. In seventeen of the forty patients, gastric acidity determinations were made before and after the twenty-four histidine treatments. Five patients showed no change in the acid curve, six showed a slight increase and six a slight decrease in degree of free and total acids. Of the six patients who showed an increase in the degree of acidity, five were symptom free and one was moderately improved, of the six patients with a decrease in acids, five were symptom free and one was moderately improved, and of the five showing no change in the acid, two were symptom free and three moderately improved.

It is therefore evident that clinical improvement does not depend on the slight alteration in acidity during treatment.

6 Effect on Ulcer as Shown by Roentgen Examination or Operation. I have obtained either roentgen or operative check of the healing or nonhealing of the ulcer in twenty-four of the forty histidine-treated patients. Four patients with gastric ulcer and two with gastroduodenal ulcer showed the same lesions to be pres-

ent after histidine treatment. One patient showed a lesser curvature ulcer four times the size of the original ulcer, he subsequently died and an autopsy showed a perforated ulcer with peritonitis. Still another patient with gastric ulcer was operated on after histidine treatment and an ulcer was found at the pylorus. Of the sixteen patients with duodenal ulcer, the roentgenologist reported "improvement" or "evidence of healing" in eight, clinically, four of these patients were symptom free, three were moderately improved, and one was unimproved at the time of the second roentgen examination. In the remaining eight the roentgenologist reported no change in the defect; all eight were symptom free. Two patients with duodenal ulcers were subsequently operated on and ulcers were found at operation.

Of the twenty-four patients checked by either roentgen examination or operation after histidine treatment, none of the patients showed disappearance of their ulcers. Of course, persistence of deformity in the duodenum as shown by roentgen examination is not indicative of activity or nonhealing of the ulcer.

Bulmer<sup>3</sup> reports "58 per cent of symptomatic cures with disappearance of the abnormal x-ray findings." However, it should be noted that thirty-five of the patients in his series of fifty-two had gastric ulcers. Of the thirty who became symptom free with normal roentgenograms, twenty-two (73.3 per cent) were in the gastric ulcer group. It is well known that gastric ulcers frequently disappear on diet-alkali management.

**7 Reactions.** Sixteen (40 per cent) of the forty histidine-treated patients developed mild reactions. These occurred only in the patients treated ambulatory. No reactions were observed in the hospital patients. After the second, third, fourth, or fifth injections these patients complained of weakness (particularly in the knees), a tired feeling, aches and pains in the muscles of the arms and legs, and a feeling of being "all in" and "run down," as if they had the 'grip'. The patients had no chills, fever, vomiting or abdominal pain. They were not examined for leukocytosis. Two of the patients were so 'run down' that each had to rest in bed for twenty-four hours. After injections one patient experienced severe temporal headaches with pain in the eyeballs associated with lacrimation. His symptoms were of three days' duration and so severe that he could not sleep at night.

Of the sixteen who experienced these reactions, eleven became symptom free, four were moderately improved and one was unimproved.

Five of the ambulatory and six of the patients in the hospital group became symptom free without having the reactions.

Obtaining a reaction therefore does not mean that the patient will become symptom free, nor is it necessary for success in treatment.

#### ULCER PATIENTS TREATED WITH INJECTIONS OF DISTILLED WATER

To determine whether the remissions obtained by histidine injections were a direct result of adding this amino acid—which the ulcer patient lacks—as Weiss and Aron premise, I am at present treating ulcer patients with daily injections of 5 cc of distilled water as controls similar to the foregoing series. Of twenty patients so far treated the results so far compare favorably with those obtained after histidine injection. Twelve, or 60 per cent, became symptom free (compared with 55 per cent of the forty histidine patients); five became symptom free after the first injection of

distilled water, three after the second, two after the third, one after the fourth, and one after the fifth injection of distilled water. However, the number of patients is too small and the follow up too short for definite conclusions. The results with injections of distilled water will be given in a subsequent communication.

#### INDICATIONS FOR THE USE OF HISTIDINE TREATMENT

In my experience, I do not know of any one method of treatment that produces remission in "all" ulcer patients, notwithstanding several reports in the literature. In evaluating the high percentage of favorable results with histidine or the other "newer" methods, one must take into consideration the natural life cycle of peptic ulcer. Many ulcer patients develop spontaneous remissions. Not infrequently patients become symptom free immediately after intake of the barium sulfate mixture for x-ray study. Two patients scheduled for histidine treatment became symptom free immediately after barium intake and before histidine was given. Moreover, good results are obtained in many patients under the standard diet-alkali-antispasmodic regimen. Unless these facts are taken into consideration, one is prone to become "overenthused" by newer procedures.

Results obtained in forty patients (table 2) do not warrant routine injections of histidine in all ulcer patients. The expense involved, the daily visits to office or clinic, the twenty-four consecutive intramuscular injections, the mild reactions experienced by an appreciable number (40 per cent) of patients, the high percentage of recurrences (85 per cent) within six months after treatment, and, what is more important, the fact that approximately the same percentage of patients respond favorably to the diet-alkali regimen without histidine injection—these speak against the routine use of histidine in ulcer therapy.

Histidine therefore should not replace the usual diet-alkali management of ulcer. However, it may be very valuable as "extra artillery," when such is deemed necessary. Ulcer patients should first be placed on an ulcer diet with frequent feedings and alkalis. In addition, local heat, antispasmodics, sedatives and aspiration should be prescribed when indicated. Mental rest should be repeatedly stressed. Attention should also be given to coexisting disorders, as focal infection, constipation, hyperthyroidism and emotional conflicts. If patients prove refractory on these regimens, histidine injections may be valuable. About 50 per cent of our patients not responding to the diet-alkali management become symptom free and an additional 20 per cent moderately improved. As an adjuvant to our therapeutic armamentarium, therefore, it is of value.

#### MILCHMANISM AND RATIONALE OF THE HISTIDINE TREATMENT

Weiss and Aron<sup>26</sup> assumed that their dogs which had been operated on developed peptic ulcers because of a deficiency or absence of the amino acid histidine. They state that the operation deprived the jejunal secretion of pancreatic trypsinogen, thereby preventing the breaking down of the gross polypeptides into their assimilable components the amino acids. They were unable to produce ulcers when histidine was furnished by injection. These facts caused them to formulate the histidine deficiency theory for ulcer production in man and form the basis for the present histidine ulcer therapy.

This experimental evidence, however, does not conclusively prove that peptic ulcer, either in experimental dogs or in man, is a result of histidine deficiency. As a matter of fact, numerous experiments by various workers definitely point in a different direction.

Mann and Williamson<sup>20</sup> transplanted the common bile duct and the pancreatic duct into the terminal ileum, leaving the duodenum in its normal position. Neither trypsinogen nor trypsin could reach the jejunum. Amino acids or histidine could not be formed. Only 50 per cent of the animals developed ulcers, 50 per cent did not.

Hoerner<sup>42</sup> reports that evulsion of the pancreatic ducts, preventing the pancreatic secretion from reaching the intestinal tract, is rarely followed by ulcers. The pancreatic proteolytic pro-enzyme in these animals could not reach the intestine. Proteins thus could not be broken down into the amino acids. According to Weiss and Aron, there should be a deficiency or lack of histidine. Yet ulcers rarely developed.

Mann and Williamson<sup>20</sup> eliminated the entire normal mechanism for receiving the acid-gastric contents by deviating the duodenum together with all the secretions poured into it. In this series of experiments, as well as in Weiss and Aron's experiments (on which they base their histidine deficiency theory of ulcer) the jejunum was thus deprived not only of trypsinogen but also of the pancreatic amylolytic enzyme (amylase), the pancreatic lipolytic enzyme (lipase) of bile (bile salts, acids and pigments) and of the duodenum with the protective mechanism of the duodenal mucosa and secretion. By depriving the jejunum of all these there is a disturbance not only in protein metabolism but in the carbohydrate and fat metabolism as well. There is in addition a disturbance in the acid-alkali relationship in the jejunum compared with the normal jejunum, and a change in the mechanical factors as described by Mann and Williamson<sup>20</sup> and by Morton<sup>43</sup>. In short, there is a total disturbance of all the biochemical processes of digestion. In this group 95 per cent of the animals developed chronic callous ulcers.

Morton<sup>43</sup> repeated the experiments of Mann and Williamson. In addition, he reports that, on performing a gastro-enterostomy after the ulcers formed, "in every case the original jejunal ulcer showed unmistakable evidence of healing" while the duodenum and both bile and pancreatic ducts still drained into the ileum. These ulcers healed in spite of the fact that there was a so-called histidine deficiency. However, coincident with the healing of the original ulcers, new ulcers formed in the efferent loops of the gastro-enteric anastomosis. "The acid alkali imbalance following surgical duodenal drainage," he states, "and the force with which the contents emptying from the stomach impinged directly on a relatively circumscribed area of the intestinal wall, are suggested as having an important bearing on the formation of ulcers."

Mann and Williamson,<sup>20</sup> Morton,<sup>43</sup> Mann and Bollman,<sup>44</sup> McCann,<sup>45</sup> Ivy and Fauley,<sup>22</sup> Matthews and Dragstedt<sup>46</sup> and more recently Harper<sup>47</sup> have referred

to three factors as significant in the development of peptic ulcer in surgical duodenal drainage: the chemical factor, the mechanical factor and the susceptibility of the mucosa. All these factors seemed to be of significance in the production of the experimental ulcers described.

Ivy<sup>48</sup> writes that "Weiss and Aron did not 'run' their Exalto-Mann-Williamson dogs long enough. The Exalto-Mann-Williamson operation, because of the digestive disturbance it creates, has a mortality per se, i. e., such a dog may die at from three to ten weeks without ulcer. In the therapeutic studies we have been conducting during the past four years on Exalto-Mann-Williamson dogs, we have observed this frequently. In order to interpret the results of our therapy, we operated on forty-two dogs for control. Of the forty-two untreated control dogs all died from jejunal ulcer in from fourteen to 120 days postoperatively, the average being seventy-eight days. When the presence of ulcer was diagnosed by blood in stools or gastric analysis, it was found that only 50 per cent of the dogs developed ulcer prior to seven weeks (forty-nine days), all had not developed ulcer until fourteen weeks postoperatively. So I cannot place much weight on the results reported by Weiss and Aron." Weiss and Aron<sup>26</sup> examined two of their four dogs post mortem five weeks after histidine-tryptophan treatment, one after six weeks and one after ten weeks.

It is difficult, therefore, to see why the disturbance in the protein metabolism and the deficiency in histidine (if there is such a deficiency) is blamed solely for the resultant ulcer. Enzymes, bile, and the disturbance in carbohydrate and fat metabolism, as well as the chemical and mechanical factors and susceptibility of the mucosa, are hardly considered by Weiss and Aron in the process of ulcer formation. The very basis of Weiss and Aron's histidine-deficiency theory is questioned by Ivy<sup>48</sup> when he states that "Weiss and Aron did not 'run' their Exalto-Mann-Williamson dogs long enough" after histidine-tryptophan injections.

It appears that there is no sufficient scientific evidence that a deficiency of histidine is the cause of peptic ulcer. The experiments performed by Mann and Williamson,<sup>20</sup> Hoerner,<sup>42</sup> Morton,<sup>43</sup> Mann and Bollman,<sup>44</sup> McCann,<sup>45</sup> Ivy and Fauley,<sup>22</sup> Matthews and Dragstedt<sup>46</sup> and Harper<sup>47</sup> do not point in this direction. Confirmatory work by other investigators of Weiss and Aron's experiments have not been reported. Clinical end results after histidine injections in my series of ulcer patients do not give a sufficiently high percentage of remissions to point in favor of the histidine deficiency theory.

In my opinion, histidine represents one of a number of substances<sup>49</sup> that may be useful as "extra artillery" if patients prove refractory to the standard diet-alkali ulcer regimen. Remissions, when they result after these injections, may be explained by one or more of the following:

- 1 The intermittent nature of the disease. Ulcers are characterized by symptom-free intervals and relapses. Persistence of treatment, therefore, is important. A symptom-free interval may follow.

- 2 The psychic effects added confidence in "something new," instead of "the same old diet and powders" so well known to ulcer patients, also greater encouragement due to more frequent visits to physicians, as well as more careful and longer observation.

<sup>49</sup> Footnotes 1-12.

3 A nonspecific protein reaction It is thought that local cellular injury leads to the absorption of protein, affecting the chronically inflamed locus (the ulcer) by stimulating leukocytosis, mobilization of immune bodies, dilatation of capillary vessels, and so on

4 A nonspecific action on the sympathetic nervous system which in some way influences the nervous control of the ulcer area, inducing hypomobility and hypoperistalsis

#### SUMMARY

1 Of sixty-seven patients with peptic ulcer, fifty-three were treated with a diet-alkali regimen and forty patients with histidine

(a) Of the patients treated with diet-alkali, 51 per cent became symptom free and 207 per cent were moderately improved (a total of 717 per cent of favorable responses) Of the patients treated with histidine, 55 per cent became symptom free and 20 per cent were moderately improved (a total of 75 per cent of favorable responses)

(b) Of seventeen patients treated with histidine after the diet-alkali management failed to produce remissions, 52.9 per cent became symptom free and 17.6 per cent moderately improved (a total of 70.6 per cent of favorable responses)

(c) Of nine patients treated with the diet-alkali after histidine failed to produce remissions, 42.8 per cent became symptom free and 28.6 per cent moderately improved (a total of 71.4 per cent favorable responses)

(d) By changing from one treatment to another and trying all means at hand, to "tire out the ulcer," 73.5 per cent became symptom free and 13.4 per cent moderately improved (a total of 86.5 per cent of favorable responses) Of the nine patients not responding to medical management, four had ulcer complications necessitating surgery and five had medical complications such as myocarditis, hyperthyroidism or arteriosclerosis

2 A follow up of patients who developed remissions showed that 85 per cent of the patients treated with histidine developed recurrences of ulcer symptoms within six months after treatment Of the patients who developed remissions after the diet-alkali regimen, only 31 per cent returned with ulcer symptoms within six months (table 4)

3 Twenty-four consecutive daily injections of histidine are not essential to produce a remission or prolong a symptom free period If five or six (at the most, eight) consecutive daily histidine injections do not cause complete disappearance of all ulcer discomforts, the hope of producing a remission or of prolonging a symptom-free interval by further histidine injections is negligible, based on this small series of patients

4 About one third of seventeen patients showed a slight increase in the acid curve, one third showed a slight decrease and the remaining third showed no change in degree of acidity after histidine injections Clinical improvement or failure to improve did not depend on the resultant gastric acidity curve

5 Of the twenty-four patients checked by either roentgen examination or operation after histidine treatment, not one showed disappearance of the ulcer deformity

6 Sixteen (40 per cent) of the forty histidine-treated patients developed mild reactions Obtaining a reaction does not mean that the patient will become symptom free, nor is it necessary for success in treatment

#### CONCLUSIONS

Results obtained in forty patients do not warrant routine injections of histidine in all ulcer patients The expense involved, the daily visits to office or clinic, the twenty-four consecutive intramuscular injections, the mild reactions experienced by an appreciable number of patients, the high percentage of recurrences within six months after treatment, and what is more important, the fact that approximately the same percentage of patients respond favorably to the diet-alkali regimen without histidine injections—these speak against the routine use of histidine in ulcer therapy

Histidine produced remission of ulcer symptoms in 55 per cent of the patients treated When its administration produced remission of symptoms, it did not prolong the symptom-free interval nor did it prevent recurrences, 85 per cent of the patients who developed remissions have returned with ulcer symptoms within six months after treatment

However, histidine may be used as "extra artillery" in patients not responding to the diet-alkali-antispasmodic management About 50 per cent of the latter patients may thereby become symptom free and an additional 20 per cent moderately improved

## HEMOGLOBIN AND RED CELL CONTENT OF THE BLOOD OF NORMAL WOMEN

### DURING SUCCESSIVE MENSTRUAL CYCLES

RUTH M LEVERTON, MS

AND

LYDIA J ROBERTS, PH D

CHICAGO

This is a report of one phase of an iron metabolism study of four normal college women carried out over several successive menstrual cycles Since the larger proportion of iron exists in the body in the red blood cells, this study of necessity included determinations of hemoglobin and red cell values of the blood of the subjects In view of the conflicting nature of the data available in the literature, daily determinations of hemoglobin and red cell content were made during the greater part of the study in the hope of making some contribution to this field of investigation The results of these daily determinations are herewith presented and considered in relation to the different phases of the menstrual cycle

#### LITERATURE

The literature on this subject is not extensive and the observations reported are confusing and contradictory The one point of agreement appears to be that variations in both hemoglobin and red cell values exist The relation of these variations to the different phases of the menstrual cycle, however, is not consistently demonstrated In general, the variations in the erythrocytes are more evident than in the hemoglobin, but usually the two follow the same course Some workers<sup>1</sup> have found a premenstrual rise in the erythrocytes

From the Nutrition Laboratory, Department of Home Economics, the University of Chicago

The authors received the technical assistance of Mr. Gerald Brown who took the blood samples and made the cell counts

Since space does not permit the inclusion in this article of all daily figures, copies of the same will be lent to any one requesting them

followed by decrease with the onset of the flow, others<sup>2</sup> have reported a premenstrual decrease and still others no change coincident with menstruation.

Two larger and more complete studies are in the last group. Gumpnich<sup>3</sup> found that variations occurring in both the hemoglobin and the red cell content during menstruation were not definite and concluded that it is impossible to consider that there is a definite, regular influence of the menstruation process on the blood picture. The most valuable and recent data are presented by Reich and Green.<sup>4</sup> In an effort to obtain a better idea of the erythrocyte changes in the blood and bone

determinations been made during complete and successive menstrual cycles to establish what variations are normal and therefore what variations may be expected in any phase of the cycle. The data collected in the present study on the hemoglobin and red cell content of the blood of normal women during a long-time iron metabolism study furnish a more complete record of the variations of these blood constituents than has heretofore been reported.

#### EXPERIMENTAL

Four normal college women, three of them 21 years old and one 27 years old, served as subjects. The technic of the balance study involved the weighing and analysis of all the food eaten by the subjects and the collection and analysis of all the excreta, including the menstruum, over a continuous period of three months for two subjects and of four months for the other two subjects. The diet was planned to meet all the requirements of nutrition standards for adequacy and was constant in kind and amount throughout the experimental period. Analyses now in progress indicate that the average daily intake of iron by each subject ranged from 10 to 15 mg. During her fourth and fifth menstrual cycles one subject was given daily a supplement of 5 mg. of iron in the form of ferric ammonium citrate. This was discontinued during the sixth and last cycle of the study.

Cutaneous blood samples were taken immediately before lunch each day. This time was chosen because the activity of the subjects varied less from morning to morning than at any other time. Two erythrocyte counts were made on each blood sample and accepted only if they checked within 20. This means a difference in the final values of 0.2 million cells per cubic millimeter of blood. The same technician drew the samples and counted the cells during the entire study. Each day another technician prepared and counted a second slide from one of the blood pipets. In this way the count on one blood sample was rechecked each day and each of the four blood counts was rechecked every fourth day. Hemoglobin was determined by the method of Newcomer.<sup>5</sup> The hemoglobinometer was calibrated by the oxygen capacity method of Van Slyke.<sup>6</sup>

#### RESULTS

The results of daily determinations of hemoglobin and red cell content of the blood of each subject, the averages for each five-day period, and the averages for each menstrual cycle are shown graphically in the accompanying charts.

Observation of these data shows the occurrence of day to day variations in both hemoglobin and red cell values. These variations lie mostly within the limits of experimental error, but there are occasional sharp rises and drops. A tabulation of these variations shows that of all the day to day variations calculated for hemoglobin 57 per cent is no greater than 0.5 Gm. and 80 per cent is no greater than 1 Gm. For red cell counts, 90 per cent of the variations do not exceed 0.3 million. Moreover, the variability for the entire period is small. This is indicated by low standard deviations and coefficients of variation for both hemoglobin and red blood cells. It is significant, however, that even under carefully controlled conditions of diet and activity and with the most meticulous care in technic the average standard deviation for hemoglobin is

Chart 1—Variation in hemoglobin values of normal women

marrow coincident with the various phases of the menstrual cycle they determined the hemoglobin, the red cells and the percentage of reticulocytes in the blood of six normal women twice a week for three months. They conclude that there are no definite variations in the hemoglobin and the red cells associated with menstruation. They offer as evidence of the validity of their conclusion the fact that there was no definite post-menstrual reticulocyte peak. This indicates that the bone marrow is not called on to increase its regenerative activity following menstruation.

The lack of agreement among workers is perhaps due largely to the fact that at no time have daily

0.9 Gm. Though not excessive, this deviation is large enough to place decided limitations on the significance of any single determination of hemoglobin as often made in clinical examinations by methods far less accurate than the colorimetric one used in this study. The standard deviation of the red cell values is 0.31 million, which is scarcely above the experimental error of the technique and less than the error accepted in general clinical determinations.

Since it was thought that the amount of rest might influence daily hemoglobin and red cell values, sleep records were kept for each subject. When either the absolute values or the daily variations in the hemoglobin and red cell concentrations were compared with the number of hours of sleep there was no correlation. Reasoning that perhaps there was a physiologic lag before the effects of loss of sleep were evidenced, the hemoglobin and red cell values were compared with sleep records of two nights preceding the time of each

\* Five milligrams of iron given daily in form of ferrie ammonium citrate.  
† Three daily determination.

blood determination, and still no measurable relation existed. It was therefore concluded that these daily values were not influenced by an occasional loss of sleep.

In addition to the daily variations in these blood components chart 1 demonstrates a definite upward trend of hemoglobin values for each of the four subjects over the period of the study. The increases amount in every case to 1 Gm or more of hemoglobin per hundred cubic centimeters of blood. Such a trend is not observed in the red cell values, these remain remarkably constant throughout the experimental period for each subject. Of special interest in this regard is subject A. During her fourth and fifth menstrual cycles she was given a daily supplement of 5 mg of iron in the form of ferrie ammonium citrate. The total amount of iron thus added to the diet was 225 mg. The average hemoglobin concentration expressed in grams per hundred cubic centimeters of blood rose from 13.8 for cycle 3 to 14.8 for cycle 4 and 14.7 for cycle 5. The average red cell values were 4.80, 4.80 and 5.36 million per cubic millimeter for cycles 3, 4 and 5. During cycle 6 the iron therapy was discontinued. Blood determinations for the last three days of this cycle showed that the hemoglobin and red cell content had fallen to 14 Gm and 4.53 million respectively.

The influence of the menstruation process on the blood picture is the next point for consideration. In the accompanying table the average daily hemoglobin and red cell values for each menstrual cycle for each subject are compared with the average daily values for the menstrual period in each cycle. In the entire series the differences between the averages for the menstrual cycle and the menstrual period within the cycle do not exceed the experimental error of the method. The hemoglobin for subject D for cycle 2 is the only exception to this, it averages 13.7 Gm for the cycle and rises to 15 during the five days of menstruation. From

Chart 2—Variation in red cell values of normal women

these data it appears that there is no definite consistent effect of the process of menstruation on the daily values during the entire menstrual cycle for any of the subjects. That the averages for the hemoglobin and red cell content presented in the table do not mask any regular rise and subsequent drop in either component is evidenced by the daily values plotted in charts 1 and 2.

Since it has been shown that there are daily variations in both hemoglobin and red blood cells which sometimes exceed the experimental error one may well wonder whether these greater variations occur in some definite relation to the menstrual period. In an effort to answer this question and yet lacking sufficient data for a correlation technique, the magnitude of the day to day variations in the hemoglobin and red blood cell values was calculated for four stages of the cycle. The

premenstrual period, which includes the seven days preceding the flow, the menstrual period, which varies in length according to the individual, the postmenstrual period, which includes the seven days following the cessation of the flow, and the intramenstrual period, which includes the days between the end of the postmenstrual period and the premenstrual period of the succeeding cycle. The results indicate that not only do the greater number of daily variations lie within the limits of experimental error but that when marked variations occur they do so irrespective of the different phases of the menstrual cycle.

#### COMMENT

Choosing a standard of normality with which to compare the hemoglobin values of these subjects presents difficulties because methods of determination and expression of results of such determinations by different workers are lacking in uniformity. According to the figures compiled by Peters and Van Slyke,<sup>7</sup> the normal hemoglobin content of the blood of women between 16 and 60 years expressed in terms of oxygen capacity is  $190 \pm 2$  volumes per cent. With Hufner's<sup>8</sup> factor of 1.34 for the oxygen combining power of a gram of hemoglobin it may be estimated that 19 volumes per cent oxygen represents  $\frac{190}{1.34} = 141$  Gm. of hemoglobin per hundred cubic centimeters of blood. Compared to this standard, each subject in this study was below normal in respect to the hemoglobin concentration of her blood at the beginning of the study, the values were 12.95, 12.54, 11.62 and 13.06 Gm. for subjects A, B, C and D respectively. However, these values increased to 14, 13.92, 13 and 14.3 Gm. during the period on what is believed to be an adequate diet.

The significance of these increases in average hemoglobin content is worthy of consideration. In view of the fact that the average standard deviation was 0.9 Gm. and that 23 per cent of all the daily variations which occurred ranged from 0.6 to 1 Gm. per hundred cubic centimeters, the observed rise may appear to be merely within the range of normal daily variations. However, this is hardly an adequate explanation for the constant increase of the hemoglobin of every subject. Also any consistent change in the same direction in the hemoglobin values during the experimental period would tend to increase the standard deviation. Furthermore, the figures from which the increases are calculated are averages of many daily determinations throughout the cycles and not values of single determinations.

It is interesting to calculate what these possible increases in hemoglobin concentration mean in terms of iron storage. Subject A weighs 59 Kg. With Ching and Harrop's<sup>9</sup> average figure for total blood volume of 70 cc. per kilogram, subject A would have 4130 cc. of blood. An increase of 1 Gm. of hemoglobin per hundred cubic centimeters of blood would total 41.3 Gm. of hemoglobin. Since hemoglobin is 0.34 per cent iron, this increase would represent the storage of 140 mg. of iron above that used for daily metabolic needs and for losses in the menstruum. Similarly an increase of 1 Gm. of hemoglobin per hundred cubic centimeters of blood would represent a storage of 142, 107 and 128 mg. of iron in subjects B, C and D respectively. When this storage is expressed per kilo-

gram of body weight the value is 2.3 mg. for every subject. If the increases in hemoglobin in all the subjects are significant, the storage of these amounts of iron is of practical importance. It would indicate that, although the diet contained only the standard recommendation of from 10 to 15 mg. of iron daily, this amount was sufficient to allow for storage when other dietary essentials were liberally supplied.

The addition of 5 mg. of iron daily in the form of ferric ammonium citrate to the diet of subject A during cycles 4 and 5 meant an increase of 115 mg. of iron above that furnished by the daily diet during each cycle. From the table it may be seen that the hemoglobin concentration rose 1 Gm. during the first cycle of the iron therapy and remained at this higher level during the second cycle. Three determinations made at the end of the study indicate that it had dropped 0.7 Gm. during the last cycle when the iron supplement was discontinued. It is not possible to generalize from such meager data, but certainly this is a field worthy of further investigation. Considering that a person's daily diet contains only about 10 to 15 mg. of iron, it is not surprising that a long time is required to increase hemoglobin concentration significantly when no additional, readily available iron is supplied for blood building purposes. Verification of this theorizing may be possible when the iron analysis of all the foods, feces and menstrua for each subject are complete. The question may well be raised as to whether the subjects had, at the end of the study, attained an optimum iron content of their tissues or whether succeeding months under the experimental regimen would have resulted in further storage of this mineral.

The fact that the average standard deviation of all the hemoglobin determinations is 0.9 Gm. per hundred cubic centimeters of blood when the subjects were under reasonably controlled conditions suggests the reservations necessary in interpreting the significance of single determinations.

If the standard for the normal red blood cell values for women is calculated from the figures summarized by Peters and Van Slyke,<sup>7</sup> normal adult blood with an oxygen capacity of 19 volumes per cent contains 4.8 million cells per cubic millimeter. This is higher than the standard of from 4 to 4.5 million usually given in physiology textbooks. In either case the number of red cells in the blood of these subjects is within the normal range, the mean values were 4.8, 4.6, 4.4 and 4.6 for subjects A, B, C and D respectively. In the case of subject A during the iron therapy the number of red cells increased 0.5 million during the last half of the iron therapy period. Although the significance of this may be questioned, it is of interest to note that the number decreased almost a million when the ferric ammonium citrate was discontinued.

#### SUMMARY AND CONCLUSIONS

The hemoglobin and red cell content of the blood of four normal women on a constant diet was determined almost daily for three months. Analysis of the data shows the occurrence of daily variations in both hemoglobin and red cells, the majority of which are not greater than the experimental error. The standard deviation for the entire series is 0.9 Gm. for hemoglobin and 0.31 million for red cells.

There was a definite upward trend in the hemoglobin values of every subject during the entire period. The values increased from 12.95, 12.54, 11.62 and 13.06 Gm. per hundred cubic centimeters for subjects

<sup>7</sup> Peters J. P. and Van Slyke D. D. *Quantitative Clinical Chemistry*, Baltimore, Williams & Wilkins Company, 1944, 547, 1932.  
<sup>8</sup> Hufner G. *Arch. Anat. Physiol.* 209, 1907.

A, B, C and D respectively for the first menstrual cycle to 14, 13.92, 13 and 14.3 Gm for the last cycle in the study. There is a possible significance of these increases, since they suggest a storage of measurable amounts of iron from a diet containing only the usual standard recommendation for this mineral but well fortified in other dietary essentials.

The red cell count remained remarkably constant for all subjects throughout the experiment. In one case when 5 mg of iron from ferric ammonium citrate was given daily during two menstrual cycles the red cell content increased 0.5 million per cubic millimeter and the hemoglobin content increased 1 Gm per hundred cubic centimeters. These higher values were not maintained when the citrate was discontinued.

From the data presented it appears that there is no definite or consistent measurable effect of the process of menstruation on the daily values of either hemoglobin or red cells in the subjects studied. Although occasional marked daily variations in the blood values occur, they do so irrespective of the different phases of the menstrual cycle.

The results of this study emphasize the fact that the existence of normal daily variations in hemoglobin and red cell count, even in subjects under controlled conditions, must be recognized when one judges the significance of single determinations or the influence of the menstruation process on these blood constituents.

## CHLOROSIS

ARTHUR J PATEK JR MD  
AND  
CLARK W HEATH, MD  
BOSTON

Textbooks today describe chlorosis as a disease of unknown etiology which has disappeared mysteriously. In order to define chlorosis, therefore, it is necessary to refer to descriptions written at the time when the disease was most prevalent. Although the classic account by Johannes Lunge in 1554<sup>1</sup> referred to the disease of virgins "De Morbo Virgineo" as a well known entity, and although Sydenham (1661) and Willis (1681) described the efficacy of iron therapy in the disease, the years associated with its popular recognition were from 1830 to 1900. In 1836 Ashwell<sup>2</sup> described fifteen cases of chlorosis characterized by anemia appearing in adolescent girls, invariably associated with menstrual irregularity and often complicated by gastro-intestinal or pulmonary "affections." He also commented on their depraved appetite and insufficient diet. Most accounts during the nineteenth century were in record with the description by Ashwell. It is evident that, in addition to anemia, a number of the patients had peptic ulcer or tuberculosis. Thus Bramwell,<sup>3</sup> in 1899, reviewing 314 typical cases wrote "Epistaxis occasionally occurs, but other haemorrhages are rare except in those cases in which hæmatemesis results from associated ulceration of the stomach. The anæmic condition undoubtedly predisposes to the production of the ulceration."

Later descriptions were more precise in the definition of chlorosis. Von Noorden<sup>4</sup> in 1905 described it as "a disease common at puberty and throughout the succeeding ten years, occurring in the female sex, characterized by anemia, spontaneous in origin." In reviewing 217 cases he cited a considerable number arising in the same family. Besides symptoms referable to anemia, a very large number suffered from gastro-intestinal disturbances, such as anorexia, epigastric pain, vomiting and constipation. Analysis of the symptomatology of his cases in addition to those of other authors discloses no unanimity of opinion regarding gastric acidity and menstrual disorders in chlorosis. In the majority there appeared to be normal or increased gastric acidity and likewise irregular or scanty menses. However, it is also evident from many observations that hyperacidity or scanty menses were not necessary attributes of chlorosis, likewise, that the green color was by no means essential to the diagnosis.<sup>5</sup>

In 1923 Campbell<sup>6</sup> reviewed the symptomatology of 104 cases that had entered Guy's Hospital between 1888 and 1922. His description of the disease agreed in the main with von Noorden's, and he also pointed out that an appreciable number had low gastric acidity and that in some instances the symptoms persisted several years.

Consequently the definition of chlorosis is not based on exact criteria. At best it may be defined as hypochromic anemia in adolescent girls or young women, usually associated with gastro-intestinal and menstrual disorder.

## THEORIES OF PATHOGENESIS

There have been many different explanations for the occurrence of chlorosis. Prominent among them are deficient development of the vascular system, constitutional weakness of the blood-building organs, ovarian insufficiency, digestive disturbances due to reflexes from the developing female sex organs, and neurosis or gastroparesis. None of these are tenable, since the disease is readily corrected by the administration of iron. A sound and little appreciated critical treatise was written by Stockman<sup>7</sup> in 1895, who believed that all other factors were but contributory and predisposing to two great and direct causes, "namely, blood loss and insufficient supply of iron by the food." In his analysis of three cases he found the iron intake to average between 1.3 and 3.2 mg daily. "Whereas the menses may not have been excessive, such a loss was relatively great and poorly sustained when the intake was deficient in iron. Further, girls develop with extreme rapidity from 15 to 18, throwing a great strain on the organism which suffers in various ways besides in blood forming."

Because of the supposed rarity of chlorosis and the apparent mystery that still enshrouds its etiology, four cases that entered this clinic in the past two years are presented. Since this hypochromic anemia responded readily to the administration of iron, study of causes for iron deficiency in these patients was made. In general our observations support the contention of Stockman

that chlorosis is attributable to insufficient intake of iron, to blood loss and to the demands for iron made by growth

#### CLINICAL ASPECTS

Two of the patients were 15 years of age and two were 16. In two cases the mother was definitely anemic before the birth of the patient and one of the mothers now has a pronounced chronic hypochromic anemia with achylia, glossitis, dysphagia and koilonychia. The mother of the third patient was and is definitely underweight, but there is no record of the blood picture. The grandmother of the fourth patient was treated for anemia twenty years previously at this hospital. There is no record of the mother's blood picture.

Dietary histories were taken carefully in all four cases. Their appetites were uniformly poor and capricious and their diets had been markedly deficient in meat, green vegetables and fruit for several years. The iron contents of the diets were estimated at 4.9, 5.4, 6.9 and 6.8 mg daily in contrast to the normal of about 15 mg.

In no case was there complaint of dyspepsia, nausea, vomiting or diarrhea, but the lack of appetite and particularly the lack of non-containing foods in the diet was pronounced.

Gastric analysis was performed on the four patients. In one there was normal gastric secretion. In two there was free gastric acidity only after the injection of histamine. The fourth patient had post-histaminic anacidity. This was the daughter of the patient who now has chronic hypochromic anemia and achylia. Stool examinations were uniformly negative for blood.

Symptoms arose in three of the patients one year and in one patient two years after the onset of the menses. In two cases the menses came at intervals of twenty-eight days with moderate flow for four days each; in one case at intervals of three weeks with excessive flow for one week; in another the intervals were seven weeks apart, with moderate flow for one week. In addition to the loss of blood during the menses, two patients gave a history of recurrent nosebleeds for several years without apparent local cause.

All four cases exhibited characteristic blood pictures of chlorosis with hypochromic microcytic anemia.

#### ANALYSIS OF FACTORS RESPONSIBLE FOR IRON DEFICIENCY

(a) *Growth*—The growth of these patients as determined by the height-weight gains recorded in their school reports, was normal except in case 1 in which growth was very rapid with a gain in body weight of 19 pounds (8.6 Kg.) in twenty-one months preceding entry to the hospital. With growth there is an increase not only in body surface but also in circulating blood volume. The blood volume may be approximated as 2,430 times the body surface at 14 years of age.<sup>9</sup> In the average 14-year old girl this amounts to 3,650 cc of blood and at the age of 15 years to 3,990 cc, an increase of 340 cc. There is a gain also in extra-circulatory tissue iron at this age, which provides an additional demand during growth and which may be judged equivalent to about one-tenth the circulating blood iron.

(b) *Blood Loss*—In two patients the menses were normal, in one they were increased and in one they were scanty. Whereas statistics of menstrual loss are widely variant, a conservative estimate is 50 cc per period, or

650 cc annually. This corresponds to a daily loss of about 1 mg of iron throughout the year.

Consequently, when one adds to the growth requirement of 340 cc of blood from 14 to 15 years of age the average annual menstrual loss of 650 cc, the total 990 cc of blood becomes a sizable drain on the iron store of a patient with an insufficient dietary intake.

Finally, nosebleeds provided an added insult to the depleted blood reserve in two cases. Thus patient 2 lost about two tablespoonfuls every month, or an annual loss of about 360 cc, and patient 3 lost about one cupful three times yearly, an annual loss of about 375 cc.

(c) *Diet*—It has been shown that a daily diet containing 5 mg of iron is adequate to maintain iron balance in the adult male and to maintain a normal hemoglobin level over a long period of time.<sup>9</sup> It has also been shown that only a portion of the food iron is available for hemoglobin production in experimental anemia of rats,<sup>10</sup> and, although similar studies have not been reported on man, the evidence is clear that analogous conditions exist. It is likely, then, that the adult male needs considerably less than 5 mg of iron as such daily for maintenance. Indeed, Lintzel's<sup>11</sup> studies suggest that balance can be maintained in the normal man with an iron intake of less than 1 mg daily.

TABLE 1—Average Daily Diet of Case 4

	Food	Mg of Iron
Breakfast	Tea	0.03
	Sugar	0.03
	Cream	0.07
	Bread	0.76
Luncheon	Bread	1.50
	Butter	0.06
	Fruit	0.41
Supper	Bread	0.76
	Potato	0.69
	Butter	0.06
	Meat	0.50
	Vegetable	0.30
	Milk	0.42
		5.41

In adolescent girls, however, growth and blood loss increase the iron requirement well above that of the adult male and when further hemoglobin production is demanded in the face of an established anemia still greater iron intake is obviously needed. A typical diet of the four chlorotic patients is recorded in table 1, which is the average daily diet in case 4 with iron equivalents estimated according to the analyses of foods by Toscani and Reznikoff.<sup>12</sup> Theoretically an iron intake of 5.4 mg could satisfy the maintenance needs of this patient, but with only a portion of the food iron available such a diet could not efficiently make up the hemoglobin deficit. Indeed, an optimal diet is barely helpful in overcoming chlorotic anemia. For example, patient 2 was given a diet rich in iron and protein for twenty days, during which time the hemoglobin rose from 30 to 36 per cent. Directly after this period 3 Gm of ferric ammonium citrate was administered daily and there followed a rise of hemoglobin from 36 to 73 per cent in sixteen days.

It appears, therefore, that an iron-poor diet is important not in the direct causation of anemia but rather in the failure to restore normal hemoglobin in anemia occasioned by growth and blood loss

After the normal hemoglobin concentration has been reached with inorganic iron therapy, a suitable diet is probably adequate to supply the usual maintenance needs. Thus, after reaching a normal hemoglobin concentration with iron, patient 3 has maintained this level for nine months with a good diet and no iron

COMMENT

It is apparent from the analysis of these cases that insufficient intake of iron, loss of iron by menstrual and other blood loss, and the demands for iron by a growing organism are three important factors in the production of chlorosis. It is also interesting to note that in at least two of the four cases definite evidence of anemia of the mothers was obtained. It is not unlikely that these patients inherited a meager iron store at birth<sup>13</sup> and that in childhood they may have had a larval chlorosis, which reached a clinical level when the limited iron store was taxed by menstruation and by the demands for iron made by growth. In chlorosis there may therefore be a constitutional<sup>14</sup> factor in the sense of a poor iron storage endowment.

It is interesting to speculate on the rarity of the disease now as compared to its common prevalence some years ago. Part of this decline in incidence is only apparent. With the advent of x-ray examinations and of tests for the detection of occult blood in the stool (1900-1904) many cases of so-called chlorosis would now be attributable to tuberculosis or peptic ulcer. This has been pointed out by von Hoesslin<sup>14</sup> and von Willebrand.<sup>15</sup> With accurate measures for hemoglobin determination introduced in 1902 (Sjlihl)<sup>16</sup> a group of patients considered pale would now be found to have normal hemoglobin and would be considered to have one or another nervous disorder.

However, even with the elimination of such faulty diagnoses there probably did exist a large number of cases of chlorosis. The environmental changes and the emancipation of women from a cloistered sedentary life which has taken place undoubtedly lead to a better appetite and to a diet richer in iron-containing foods.

In contrast to the rarity of severe forms, mild degrees of chlorosis are now very common.<sup>16</sup> In the routine examination of student nurses between the ages of 18 and 23 at this hospital it was found that 26 per cent of thirty-eight girls considered healthy had moderate anemia, with hemoglobin between 70 and 79 per cent (Sjlihl).

Of interest is the common finding now of hypochromic anemia in middle-aged women, particularly since Faber's<sup>17</sup> description of the syndrome in 1909. The popular recognition of this syndrome following the decline of adolescent chlorosis might indicate perhaps a shift toward a later age group. Frequently these patients give the history of having been pale or anemic in girlhood. It is impossible at present to define the relationship between the two conditions. Witts<sup>18</sup>

makes a sharp clinical distinction based on the finding of gastric acidity in chlorosis and of achylia gastrica and glossitis in the older age group. Bloomfield<sup>19</sup> however, argues that such distinctions are unwarranted and arbitrary.

There can be no doubt that the four cases presented here correspond closely to early descriptions of chlorosis. It is our opinion that the disease has not disappeared. Since its cause depends on conditions that are universally current, such as growth, blood loss and inadequate diet, it is unlikely that it should disappear.

CONCLUSIONS

- 1 Chlorosis has not disappeared
- 2 In the analysis of factors responsible for anemia in four cases of chlorosis, definite cause for iron deficiency was shown
- 3 Chlorosis is the exaggeration of a normal tendency toward anemia in adolescent girls, created by the increased demand for iron made by growth and by menstrual or other blood loss, and by diet insufficient in iron-containing foods

REPORT OF CASES

CASE 1—A girl, aged 15 years, in November 1935 complained of shortness of breath and weakness. Her father had tuberculous adenitis. Her mother was anemic at the time of the

TABLE 2—Initial Blood Counts in Four Cases of Chlorosis

\* The red blood cell in all cases were pale and small. They showed marked variation in shape. Blood platelets were normal.

patients' birth. In childhood the patient was underweight and was subject to frequent colds. Her appetite had been capricious and her diet had been poor in iron-containing foods during the past three years. In the twenty-one months preceding entry, growth was rapid with a gain of 19 pounds (8.6 Kg.).

In February 1934 several x-ray examinations of the chest were made, but no abnormality was noted. In November 1934 the catamenia began, and the menstrual periods have since recurred at twenty-eight-day cycles with four days of moderate flow. In October 1935 the patient complained of weakness, headache, palpitation and shortness of breath. There was no history of bleeding or of any disorder of the gastro-intestinal or genito-urinary tract.

The patient was very pale and tired looking. Several teeth were decayed. The papillae of the tongue were normal. The lungs and heart were normal. A soft systolic murmur was heard in the area of the pulmonary valve. Examination of the abdomen, pelvis and rectum showed no abnormality. The finger nails were thin, flat and brittle. The reflexes were physiologic.

The urine and stools were normal. Gastric analysis revealed normal gastric secretion. The blood Kahn reaction was negative. Details of the blood counts are given in table 2.

The patient improved rapidly with iron therapy. In one month the hemoglobin rose from 34 to 66 per cent. The patient felt well.

CASE 2—A girl, aged 16 years, entered the hospital in February 1934 because of weakness. Her grandmother had

19 Bloomfield A. I. Relations Between Primary Hypochromic Anemia and Chlorosis. Arch. Int. Med. 50: 328 (Aug.) 1932.

been treated for anemia twenty years before. In childhood the patient enjoyed robust health. On moving from the country to the city two years before, the family lived in cramped lodgings. The patient's appetite failed and she developed a dislike particularly for meat and green vegetables. For several years, moderate nosebleeds occurred on the average of once a month. For one year menstruation came at cycles of three weeks with excessive flow for one week. Two weeks before entry the patient fainted.

On examination she was thin, extremely pale and listless. The teeth were carious. The nose showed no bleeding point or ulceration. The papillae of the tongue were normal. The lungs were clear and the heart was normal except for a rapid rate and a systolic murmur in the area of the mitral valve. The remainder of the examination was negative.

The urine and stools were normal. Gastric analysis yielded only a trace of free hydrochloric acid after the injection of histamine. The blood Kahn reaction was negative. Detailed blood counts are listed in table 2.

With iron therapy the red blood cells increased from 2,370,000 to 4,370,000 and the hemoglobin from 29 to 87 per cent. The menstrual periods now appear at twenty-eight-day cycles with average flow. Occasional nosebleeds recur. The diet is ample and the patient feels strong. A normal blood level has been maintained four months without iron therapy.

CASE 3—A girl, aged 15 years, entered the hospital in February 1935 because of pneumonia, from which she promptly recovered by crisis. Born and brought up on a farm, the patient was in sound health until her family moved to the city. At 9 years of age, because of ill health, the patient returned to the farm for two years. Since she was 9 years of age, rather severe nosebleeds had occurred about three times a year. The menses began at 12 years and have persisted up to the present time in cycles of seven weeks with one week of moderate flow. Her appetite had been poor for several years and her diet very sparing in iron-containing foods. For two years she had been noticeably pale. For one year she had complained of palpitation, precordial ache and easy breathlessness.

The signs of pneumonia in the left lower lobe disappeared after several days. Except for pallor there were no physical abnormalities.

Urine and stool examinations were negative. Gastric analysis showed only 7 units of free hydrochloric acid after the injection of histamine. The blood Kahn reaction was negative. Detailed blood counts are listed in table 2.

With iron therapy and a suitable diet the patient made rapid recovery. The hemoglobin increased from 44 to 87 per cent in six weeks. Although no iron has been taken for nine months the patient's hemoglobin is now 96 per cent. She feels well.

The lungs were normal. The heart was not remarkable except for a rapid rate and a systolic murmur heard all over the precordium. Examination of the abdomen, pelvis, rectum and extremities showed no abnormalities. The reflexes were physiologic.

The urine and stools were normal. Gastric analysis showed complete absence of free hydrochloric acid after the injection of histamine. The blood Kahn reaction was negative. Initial blood counts are listed in table 2.

With iron therapy recovery was prompt, with a rise of hemoglobin from 40 to 81 per cent in two months. For one year normal values have been maintained with small amounts of iron, and for the past seven months without iron. Gastric analysis repeated one year after entry showed a return of free hydrochloric acid without the stimulus of histamine. Her diet is now ample in iron-containing foods, and she feels well.

## Clinical Notes, Suggestions and New Instruments

### A RULER FOR DETERMINATION OF ELECTROCARDIOGRAPHIC VALUES

ZOLTON T. WIRTSCHAFTER, M.D., CLEVELAND

A transparent celluloid ruler measuring 15 by 4 cm. has been devised, which enables one to determine auricular and ventricular rates and PR and QRS intervals directly from electrocardiographic tracings. The method generally employed at present involves the use of dividers, counting time intervals and subsequent mathematical calculations, for the determination of these values, especially rates. This comparatively cumbersome procedure, at its best, often leads to errors.

The principle on which this ruler was devised is quite simple. The motor speed of most electrocardiograph machines is so adjusted that 2.5 cm. of film is exposed per second. Hence, a record is produced in which the large interval, representing 0.20 second, covers a distance of 0.5 cm., while the small division, representing 0.04 second, extends over a distance of 0.1 cm. On this basis one can easily calculate the space covered by a single cardiac cycle at any heart rate. These values for a selected number of cardiac rates have been calculated and as seen in the accompanying illustration, vertical lines have been constructed at the corresponding distances from an abscissa at the left end of the rate scale.

The rate scale is employed in the following manner. To determine the ventricular rate, the ruler is placed over the

Ruler for determination of electrocardiographic values

CASE 4—A girl, aged 16 years, entered the hospital in November 1933 because of excessive weakness of several months' duration. Her mother had chronic hypochromic anemia with achilia gastrica, glossitis and koilonychia. For several years the patient's appetite had been poor and her diet had been sparing in meat, green vegetables and fruit. Catamenia began at 14 years with the menses appearing at twenty-eight-day cycles and lasting from three to four days with moderate flow. There was no history of bleeding or of any disorders of the gastro-intestinal or genito-urinary tract.

The patient was well developed but slim and her skin had an olive gray pallor. The teeth were in poor repair. The tonsils were hypertrophied. The papillae of the tongue were normal.

electrocardiographic tracing so that the abscissa at the left side of the rate scale coincides with point R (apex or sharp peak of ventricular complex). The corresponding point of the next cycle will coincide with the reading for the ventricular rate at that particular point in the record. The auricular rate can be determined similarly by using the apex of the auricular wave (P) instead of point R. By repeating this process at various parts of the record any arrhythmia quickly becomes apparent.

On the same basic principle, PR and QRS scales have been included in the ruler, 1 mm. is equivalent to 0.04 second. Thus when the zero line of the PR scale is placed over the

beginning of the P wave, the end of the PR interval coincides with the time value of the interval on the scale. The lines for the limits of normal, namely, 0.12 and 0.20 second, are made heavier. In a similar manner, when the zero line of the QRS scale is placed over point Q, point S coincides with the time value of the QRS interval on the scale. Again, as in the PR scale, the limits of normal of the QRS interval, 0.04 and 0.10 second, are indicated by heavier lines.

An ordinary metric scale is placed along one edge of the ruler. In addition to the usual uses of a metric scale it is intended to be employed to measure the height (voltage) of the various complexes.

In some cases, because of the haziness of the tracing some difficulty may be encountered in attempting to visualize the record clearly through portions of the ruler. This may be obviated by holding the ruler at a 45 degree angle with the surface of the record reading the beveled edge of the ruler instead of reading through the celluloid. Indeed several cardiologists who have employed the instrument prefer to use it in this manner at all times.

Examination of a large number of electrocardiographic tracings has revealed that approximately 85 per cent of all records may be accurately interpreted with this instrument. The motor speeds of the other machines vary somewhat from the standard mentioned. However, it is possible to adjust the speed of these motors to conform with the standard rate. One can quickly determine whether the ruler may be used on records from any individual apparatus by measuring the distance covered by two of the large time intervals, which distance should equal 1 cm.

The utilization of this ruler enables one to interpret an electrocardiographic tracing with greater facility than the present methods allow. Errors in mathematics are largely eliminated, since no calculation is necessary.

#### A BRACE FOR THE TRANSPORTATION AND HANDLING OF PATIENTS WITH INJURIES OF THE CERVICAL VERTEBRAE

LOUIS T. WRIGHT, M.D., NEW YORK

There has been no brace designed to my knowledge for the transportation and handling with safety of patients with acute fractures and dislocations of the cervical vertebrae. The only

Fig 1—Appearance of the brace

point stressed in making this brace was that it should be so solidly and firmly constructed that it would not slip once it had been applied. It is adjustable and any degree of hyperextension and traction on the head is easily obtained by means of four turnbuckles.

The necessity for such a brace occurred to me because we had in the wards several patients with injuries of the cervical spine whom we were afraid to move for roentgen examination.

From the Surgical Service of Harlem Hospital, Dr. C. S. B. Cassa, Director.

for fear that harm might result. It was therefore with the idea of supporting the neck during roentgen examinations in these cases that this brace was made, and for that reason the obliquely vertical rods were placed so as not to interfere with the lateral and anteroposterior x-ray views.

Fig 2—Anteroposterior view of the brace when applied

It subsequently occurred to me that the use of such a splint might possibly prove of value in the transportation of a patient with an injured cervical spine to the hospital if applied by an ambulance surgeon at the scene of the accident. The chin piece

Fig 3—Lateral view of the brace when applied

is so arranged that it can be turned down out of the way when it is necessary to take a roentgenogram through the open mouth as is the case in fractures of the atlas and axis. I make no claim for originality, as doubtless a similar apparatus has been in use although I do not know of it. The Thomas collar and

the Young head piece attached to the Taylor brace will maintain a certain degree of hyperextension of the head, but they are used during the convalescent period, after reduction and plaster cast immobilization, and they are too unstable to depend on during the acute dangerous period when further displacement may occur. There has been insufficient emphasis placed on the management of this phase in the treatment of these injuries, and if this note stimulates an added interest in this special problem it will be more than worth while.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT  
HOWARD A. CARTER Secretary

### COMPREX SHORT WAVE DIATHERMY UNIT ACCEPTABLE

Manufacturer: Compres Oscillator Corporation, New York

This unit is recommended by the manufacturer for medical and surgical diathermy. Standard equipment includes cuff electrodes and attachments for tissue cutting and coagulation.

The machine is of the two-tube oscillator type, with a patient circuit inductively connected to the tank circuit. The power input is about 660 watts, and the wavelength between 15 and 16 meters. Since there is no acceptable method for measuring the output power of diathermy machines, this value is not stated. Operating the unit under full load for two hours indicated that the temperature rise of the transformer and of the cabinet was within the limits of safety established by the Council. The shipping weight is about 52 pounds. Figure 2 is a diagram of the circuit.

Fig. 1—Compres Short Wave Diathermy Unit

The tissue heating ability of the machine was investigated and the evidence submitted was verified in a clinic acceptable to the Council. Cuff electrodes, about 6 cm wide and about 57 cm long, were used. When applied to the patient, the cuffs were separated from the skin by about 17 cm spacing, consisting of cellucotton pads. The distance between the center of the cuffs is about 20 cm. Thermocouples were introduced into the subcutaneous and deep-lying tissues (quadriceps extensor) of the human thigh. The machine being operated at the patient's tolerance, the temperature rise (average of eight tests) was observed at the begin-

Fig. 2—Schematic diagram of the circuit

ning and end of twenty-minute application periods the thermocouples being removed during the treatment. According to the results of this test the temperature rise of the deep-lying tissues of the thigh was higher than that obtained with conventional diathermy—the criterion for evaluating short wave machines which the Council has adopted.

In a clinic acceptable to the Council this apparatus was used for fever treatment. If the proper technique is used under the supervision of a qualified physician this device may be expected to produce hyperpyrexia. The physician should safeguard the

patient by using safety methods employed in operating rooms for major surgery.

In view of the favorable clinical performance of the machine when using the cuff electrodes, the Council on Physical Therapy voted to include the Compres Short Wave Diathermy Unit in its list of accepted apparatus.

## Council on Pharmacy and Chemistry

### HISTIDINE HYDROCHLORIDE

IN THE CONSIDERATION OF A COMMERCIAL PREPARATION OF HISTIDINE MONOHYDROCHLORIDE (LAROSTIDIN ROCHE) PROPOSED FOR USE IN THE TREATMENT OF PEPTIC ULCER, THE COUNCIL ON PHARMACY AND CHEMISTRY WAS CONFRONTED WITH THE PROBLEM OF THE THERAPEUTIC VALUE OF THE DRUG IN THIS CONDITION. AT THE REQUEST OF THE COUNCIL'S REFEREE A STUDY WAS MADE BY DR. KIRBY A. MARTIN OF THE SYMPTOMATIC AND RADIOLOGIC RESPONSE OF A SERIES OF FORTY-ONE PATIENTS TREATED WITH A SOLUTION OF HISTIDINE MONOHYDROCHLORIDE AS COMPARED WITH THAT OF FORTY PATIENTS TREATED WITH THE USUAL DIET ALKALI REGIMEN. THE RESULTS ARE REPORTED IN THE FOLLOWING PAPER, WHICH DR. MARTIN SUBMITTED FOR THE COUNCIL'S CONSIDERATION. THE COUNCIL ADOPTED DR. MARTIN'S REPORT AUTHORIZING IT FOR PUBLICATION WITH EXPRESSIONS OF HIGH APPRECIATION OF THE EXCELLENT WORK DONE BY THE INVESTIGATOR. THE COUNCIL POSTPONED FURTHER CONSIDERATION OF HISTIDINE HYDROCHLORIDE TO AWAIT ADEQUATE CLINICAL EVIDENCE OF ITS THERAPEUTIC VALUE.

PAUL NICHOLAS LEECH Secretary

### HISTIDINE HYDROCHLORIDE VERSUS DIET AND ALKALIS IN TREATMENT OF PEPTIC ULCER

THE IMMEDIATE AND LATE EFFECTS IN FORTY-ONE CASES

KIRBY A. MARTIN, M.D.  
NEW YORK

Since the use of histidine hydrochloride in the treatment of peptic ulcer was introduced by Weiss and Aron in Strasbourg in 1933,<sup>1</sup> a widespread interest has been aroused in this substance. Increasing numbers of communications have appeared in the literature, first in Europe and more recently in this country, and for the most part these reports lend great encouragement to histidine therapy as a means of treating this perplexing condition. While the etiology of peptic ulcer still remains obscure, the present high standard of diagnostic accuracy enables one to establish a fairly correct criterion by which therapeutic substances may be judged. It seemed desirable, therefore, to study the results of histidine therapy on a selected group of patients with peptic ulcer, with the intention of observing not only the immediate effects, as heretofore reported, but the sustained effects of this treatment.

The Strasbourg workers based their clinical observation on previous experimental investigation. They reasoned that, since ulcers could be so readily produced in dogs by the Mann-Williamson technique,<sup>2</sup> the cause of

3 The Mann-Williamson (Mann F. C. and Williamson C. S. The Experimental Production of Peptic Ulcer. *Ann. Surg.* 77: 409 [April] 1923. Mann F. C. *Am. J. Surg.* 7: 453 [Oct.] 1929) operation has for its object the diverting of the pancreatic juice and bile together with the duodenal secretion into the terminal ileum. This is accomplished by resecting part of the duodenum, anastomosing the distal end with the terminal ileum and closing the proximal end of the loop, the continuity of the stomach and the distal duodenal loop being restored by an end-to-end anastomosis.

such ulcers might be the loss of some vital substance produced in the duodenum of that animal. Since some of the amino acids are normally produced in the duodenum by protein cleavage, they thought that an amino acid deficiency might occur in peptic ulcer and that erosion and ulceration might result from the acid chyme when the cells of the gastro-enteric walls were deficient in these vital substances. They decided to investigate the effects of some of the amino acids as a substitution therapy with the hope of preventing ulcers or healing those already produced.

Weiss and Aron carried out the Mann-Williamson technique on five dogs, two were kept as controls and the remaining three animals received daily intramuscular injections of histidine and tryptophan. (Later it was stated that tryptophan was without effect.) The control animals lost weight had blood in the feces, and developed a severe anemia. One was killed at the end of three weeks and "four small ulcers were found." One died of a perforated jejunal ulcer in the sixth week. The three treated animals lost weight and were anemic, but no blood was found in the feces. The treated animals were killed, one at five weeks, one at six weeks, and one at ten weeks after the experiments were started. "No ulcer was found in any of these three animals. As a result of further experimentation it was pointed out that histidine treated animals later died of emaciation."

These workers concluded from their observations that tryptophan and histidine would prevent ulcer formation, although the animals became anemic and cachectic, and developed profuse diarrhea but without melena. They explained the beneficial effects of histidine as providing a substance that "better the trophism of the gastro-enteric wall." They immediately tried either histidine or histidine and tryptophan on a few patients with peptic ulcer. They report that in all the cases the symptoms disappeared after a few injections but that in many of them the radiologic signs persisted. A preliminary report of a further series showed "rapid disappearance of vomiting and pain, intestinal hemorrhage rapidly checked, little or no effect on gastric acidity, x-ray changes variable—recent ulcers disappeared, the callous ones persisted, and the periodic crises were aborted." More recently Aron<sup>4</sup> has reported similar immediate effects in forty-two cases.

Fontes and Bauer<sup>5</sup> repeated the experimental work of Weiss and Aron but, instead of employing the parenteral method, gave the histidine orally in doses of from 0.25 to 0.5 Gm daily. The procedure was carried out on 100 dogs and the formation of ulcer was prevented in 30 per cent. When ulcer did occur it was much smaller than that present in the untreated animals. They were unable to find any relation between the quantity of histidine ingested daily and the non-appearance of the ulcer. However, when they doubled the quantity of histidine ingested the length of survival was almost doubled. The animals in which no ulcer was found eventually died. These authors questioned histidine as being the sole factor in the nonappearance of experimental ulcer.

Blum<sup>6</sup> was among the first to report the clinical benefits derived from histidine. He kept his patients on normal diets and found that the acute symptoms

promptly improved. Lenormand,<sup>7</sup> Richards,<sup>8</sup> Stolz,<sup>9</sup> Bogendoerfer,<sup>10</sup> Hessel<sup>11</sup> and others have similarly reported the initial benefits observed from this therapy, but the number of cases studied was small and the follow up insufficient. Bulmer<sup>12</sup> reported fifty-two unselected cases of peptic ulcer treated with histidine. All but three of the patients were kept ambulatory. His immediate results were (1) thirty symptomatic cures with disappearance of the abnormal roentgen observation, (2) ten symptomatic cures with persistence of some roentgen abnormality, and (3) twelve failures. No appreciable change in gastric acidity was noted. Later, three patients relapsed. Cases of gastric ulcer seemed to him to be more amenable to this treatment than did those of duodenal ulcer. A few of his patients were followed as long as ten months.

In this country, Volini and McLaughlin<sup>13</sup> have made a preliminary report on twenty-one patients with peptic ulcer who were treated with histidine. All their patients were kept ambulatory and on "liberal diets" but were detailed at duties in the hospital. These investigators reported rapid clinical improvement, characterized by the relief of pain, vomiting, hypersecretion and gastric retention. Appetite and weight increase was noted. Eads<sup>14</sup> made a preliminary report on thirty-five cases of peptic ulcer (thirty duodenal and five gastric) treated with histidine. All his patients were kept ambulatory and on "slightly modified diets." His results were clinical and x-ray evidence of immediate healing in six cases, the same evidences of improvement but less rapid in eight cases, amelioration of symptoms with x-ray examinations unchanged in nine cases, and no improvement in twelve cases. The author reports less beneficial effect than is recorded in previous papers. His observations extended over six months.

Rafsky<sup>15</sup> reported twenty-four duodenal, one marginal and one gastric ulcer treated with histidine. Most of his patients were confined to bed. The diet varied from a "Sippy to a regular diet." He observed marked diminution of acidity. Symptomatic relief was obtained during treatment in nineteen of his patients, all of whom remained symptom free during his observation extending over four months. He did not estimate what effect bed rest and change of diets might have had on his patients.

#### HISTIDINE

Histidine was discovered by Kossel in 1896 among the decomposition products of the protamine of sturgeon testes, but it was not until 1904 that its structure was definitely determined by Pauly Wendhouse and Knopp.<sup>16</sup>

Histidine is a constituent of most of the simple proteins and may be obtained from a great variety of foodstuffs most important of which are beef, eggs, fish

and milk. It is found in much larger quantities in blood and it is from this source that it is derived commercially.

It seems to be a fairly established fact that certain of the amino acids—for example, tryptophan and histidine—are indispensable for the maintenance of a normal nutrition. The animal organism does not possess the ability to synthesize histidine, nor can another amino acid replace it. On the other hand, there is no convincing evidence from feeding experiments that a deficiency of this substance can be produced in animals. The presence of histidine in foodstuffs is so universal that the exclusion of histidine-producing foods would make the diet incomplete in other indispensable dietary factors.<sup>17</sup>

Since histidine-containing proteins are always present in a normal diet, it follows that histidine must necessarily be a normal constituent of the intestinal contents. The absorption of the amino acids, either in their simplest form or as a more complex structure, is regarded as a normal process of digestion.

#### METHOD EMPLOYED IN THE PRESENT STUDY

Eighty-one patients with active symptoms of peptic ulcer and positive radiologic evidence were chosen from

TABLE 1—Immediate and Late Effects from Histidine Treatment in Peptic Ulcer Forty-One Cases

\* Trace lost of two of these patient

our clinic for this study. They were allotted impartially to one of two groups: (1) the histidine group and (2) the diet-alkali or control group.

**Selection of Patients.**—We considered the selection of patients of the utmost importance. The requirements of the study did not permit the selection of more than one in ten of the ulcer patients who came to the clinic. The patient's close residence to the clinic, his intelligence and cooperation, and his willingness to undertake such a time-consuming procedure were important factors. All the eighty-one patients were kept ambulatory and at their usual work, with the exception of three in the histidine series who were hospitalized because of the acuteness of their symptoms at the beginning of their treatment. Fairly young individuals in whom there were no concomitant organic diseases to obscure the clinical picture were given preference. All the cases selected were confirmed radiographically and in most instances a crater was visualized. More patients with duodenal ulcer than gastric ulcer were included because of the greater frequency and the chronicity of the former and the tendency of the latter to disappear, leaving no trace, regardless of the therapy used. No attempt was made to limit the ratio of the female to the male patients. The evidence presented suggested that the duration of the ulcers in this group varied from one to seven years.

It is unusual in a large clinic to find a patient seeking relief for his ulcer symptoms who does not give a history indicating that his ulcer has existed for at least a year and in most instances for several years. It is also the rule rather than the exception that these patients have had one or more "medical cures" even though a positive diagnosis may not have been made before coming under our observation. Chronicity and rhythmicity are the rule and not the exception.

I do not wish to convey the impression that the patients chosen for this study were those with deep calloused ulcers, amenable only to surgical intervention. On the contrary, they were a medium young group with no demonstrable disease other than duodenal or gastric ulcers, and with acute symptoms that would be expected to react favorably to the usual diet-alkali regimen.

**Management of Patients.**—Patients of both groups were examined and treated in the routine way to eliminate as far as possible extrapsychogenic factors. They were examined by the various members of the staff; the daily injections were given by the nursing staff to those in the histidine group; the radiographic examinations were carried out by the regular staff of that department without knowledge as to which patients were included in this study.

#### HISTIDINE SERIES

There were forty-one patients in this group, thirty-two men and nine women. Thirty-eight had duodenal ulcer, two gastric ulcer and one marginal ulcer. Their ages ranged from 18 to 62 years, averaging 37 years. The histidine<sup>18</sup> (4 per cent aqueous, isotonic histidine hydrochloride) was given intramuscularly in 5 cc doses daily (omitting Sundays) for from twenty to twenty-four days. The diet and medication were those on which the patients had previously been placed, in our clinic, elsewhere or by themselves. In most instances they were found to be on a high calory, low residual diet with little or no medication. It was deemed advisable to make no changes, as far as possible, in their diet or medication while they were under observation. Six of these patients were first given 5 cc of physiologic solution of sodium chloride for six days and then switched to histidine injections without their knowledge of the change.

**Results.**—The immediate and sustained effect of histidine on this group can best be demonstrated in table 1.

**At the Completion of the Injection.**—Thirteen of the forty-one cases showed a decreased gastric acidity, twenty showed an increased gastric acidity, and one showed no change in gastric acidity. For one reason or another, this procedure could not be carried out on seven of the forty-one patients. Twenty-six of the patients gained weight, five lost weight and ten showed no change. The gain in weight was in most instances in direct ratio to the relief of symptoms and the increased caloric intake.

The relief of symptoms, when it occurred, usually appeared early in the treatment, at about the fifth to the seventh injection. It was not uncommon for the patient to experience a moderate increase of gastric distress after the injections had been started and just before obtaining relief from symptoms. No other local or systemic reaction was noted. Three of the six

<sup>17</sup> Mitchell, H. H. and Hamilton, T. S. *The Biochemistry of the Amino Acids*. New York: Chemical Catalog Company, 1929.

<sup>18</sup> Twenty-eight patients were treated with Larostidin (Hoffmann-LaRoche) and thirteen with a 4 per cent aqueous isotonic solution of histidine hydrochloride prepared especially for this investigation. There was no apparent difference in response to these two preparations.

patients receiving saline injections became symptom free before the histidine was started

In thirty-three of the forty-one cases there was radiologic evidence of a crater before treatment, in twenty-two, the evidence persisted after treatment. In one case a crater was demonstrated after treatment when it had not been demonstrated before. Fourteen were symptom free and showed radiologic evidence of healed ulcer. Twelve were symptom free and showed radiologically that the ulcer was not healed. Eleven had persistent symptoms and gave radiologic evidence of healed ulcer. Four of these eleven patients have since been operated on, one for a marginal ulcer, one for a medium sized gastric ulcer, and two for duodenal ulcer, of the latter, one patient had persistent pain and one repeated hemorrhages. Two patients have refused operation that was advised because of the radiologic and clinical evidence. The five remaining patients showed nothing unusual in the radiologic or physical examination. However, two of them have been unable to solve their matrimonial difficulties, another is a young ambitious actor who has been unemployed for two years and has had recurring attacks of pain, a fourth, a man aged 56, who before 1929 had an excellent income, now finds himself unable to make adjustments to a meager wage, and the last, a young man, an electrician, unemployed for one and a half

since been operated on. The time that has elapsed since these patients were placed on a five feeding alkaline ambulatory regimen varies from ten months to one year. Up to the present time sixteen have remained symptom free, whereas twenty-four have had one or more relapses.

#### COMMENT

The apparent high response to a regimen that permits a patient with acute peptic ulcer to follow a liberal diet and remain at work appears very promising indeed. But, on further observation of these patients, not only does hope vanish but one can see the fallacies on which some of these preliminary deductions were based.

The work of Mann and Williamson has been confirmed and is now well recognized. It has contributed toward the understanding of the production and healing of a type of chronic ulcer. These observers believe that chronic ulcers in dogs are identical with chronic peptic ulcer in man. They point out that the production of chronic ulcers in dogs is the result of two significant factors, the chemical and the mechanical. Further, they demonstrate that these ulcers will heal readily if protected from the gastric contents.

Since the experimental work of Weiss and Aron, on which histidine therapy is based, was carried out on the Mann-Williamson animal, it would appear that their observations were correct but were insufficient to support their conclusions. It is not clear that an amino acid deficiency existed in their animals, nor can one be sure that ulcers ever existed or were prevented in the three animals studied.

It must also be admitted that the normal physiology of the animal was pretty well deranged by the Mann-Williamson operation. Not only does derangement prevent the alkaline duodenal secretions from protecting, by neutralization, the tissue adjacent to the stomach but in this instance the adjacent tissue (jejunal) is unaccustomed to receiving such secretion. When the jejunum of these dogs is exposed, without the protection of a normal cellular amino acid content to a continuous outpouring of acid chyme, it is hardly to be expected that ulcer will not develop. Nor could one expect to empower these cells with a function never intended by supplying this supposedly deficient element.

It has been shown by Matthews and Dragstedt<sup>19</sup> that the more unaccustomed a tissue is to receiving the gastric secretion, the higher is the incidence of ulcer. These workers produced experimentally a counterpart of the ulcer of Meckel's diverticulum in man by implanting a small isolated pouch of gastric tissue in the small intestine of animals at different distances from the duodenum. When the gastric tissue was implanted in the jejunum ulcer resulted just distally to the implant in 85 per cent of the instances, but when it was implanted in the ileum ulcers resulted in 100 per cent of the instances. Had Weiss and Aron supported their observations by a series of experiments using this technique and proved that ulcers thus produced could be healed or prevented by supplying the deficient amino acid in question it would have been a more convincing piece of evidence.

Fontes and Bauer confirmed the work of Weiss and Aron but gave histidine by mouth instead of intramuscularly. This would suggest that histidine as such is absorbed readily from the intestinal tract. Certainly it is abundant in the diet of man, since it is a normal derivative of proteolysis metabolism. What set of circum-

years, lost a 6 year old daughter with septicemia in 1932 and a second, aged 4 years, following an acute mastoiditis in 1934.

*Follow Up*—The period of time that has elapsed since the completion of the injections varies from six months to one year. Thirty-two patients have been under observation over ten months. Of the thirty patients rendered symptom free by this regimen, there are at this time thirteen still symptom free. Twenty-six patients have had one or more relapses, and two patients have been lost.

It is interesting to note in which group the largest number of relapses occurred. Of the twelve cases presenting a persistent crater but symptom free, only three have remained asymptomatic, whereas of the fourteen cases rendered symptom free and in which no crater could be demonstrated after treatment, ten have remained asymptomatic.

#### CONTROL SERIES DIET ALKALI REGIMEN

There were forty patients in the control series: thirty-six men and four women. Thirty-seven had duodenal ulcers and three gastric ulcers. A crater was demonstrated in thirty-five of the forty cases. The ages of this group ranged from 19 to 64, averaging 39 years. They received the alkali therapy and ambulatory diet of five feedings a day which is routine in our outpatient clinic as well as in many clinics elsewhere.

*Results*—At the end of the first month of treatment or period corresponding to the completion of the histidine treated group, thirty-one of these patients were symptom free. Three of the remaining patients have

<sup>19</sup> Matthews W. B. and Dragstedt L. R. The Etiology of Gastric and Duodenal Ulcer. Surg. Gynec. & Obst. 55: 263 (Sept.) 1932.

stances would lead to a deficiency of this substance would be difficult to understand. It is my impression that a careful survey would show that the ulcer patient receives a diet better both in quality and in quantity than the average American adult, granting, in advance, that his habits of taking food are usually faulty.

Another explanation of the action of histidine would seem to fit the facts more closely. Evidence is available in the literature to support the contention that the eroded area of an ulcer may need but little protection not only to relieve the acute symptoms but also to promote healing. Gastric mucin has been employed with some justification as a therapeutic agent in this connection. It probably exerts a protective effect on the membranes with which it comes in contact by virtue of its viscous nature and perhaps because of its buffer action, and recent reports<sup>20</sup> indicate that a symptomatic relief is obtained in from 63 to 93 per cent of the cases studied. The palliative effects of histidine in the treatment of hay fever have been reported by Lenormand.<sup>21</sup> He observed an increased flow of nasal mucus following its injection. The hypersensitive membranes, he states, are protected from the pollens. It is conceivable that the gastric mucus in a patient with a peptic ulcer might be stimulated in a similar way, thus giving relief of gastric symptoms similar to that obtained from gastric mucin. The work of Manginelli<sup>22</sup> tends to support this contention. He observed a better "analgesic effect" in acute ulcer pain when the histidine was given just before food was taken.

The many strange and unexplained conditions under which the acute symptoms of ulcer may subside are common experience. Fractional analysis made at the time of acute symptoms may show the gastric acidity to be high or low. Following the taking of a little food or soda, which usually gives immediate relief, the gastric acidity might be slightly lowered and then rise to a higher level than before. The relief from pain that follows gastro-enterostomy or the free bleeding from an ulcer is not easily explained. Remissions of symptoms sometimes occur in the absence of treatment or from a placebo of saline solution, as was demonstrated in this work in a few instances. A patient on a vacation may, and frequently does, become asymptomatic. The discouraging feature is that the symptoms usually recur similarly in the same strange manner. These facts are pointed out to make clear that the relief of symptoms is not a specific action of histidine, and the subsidence of symptoms alone cannot be taken as a criterion that the ulcer is healed.

Subsidence of acute symptoms following a strict Sippy regimen is so common that it is frequently regarded as a diagnostic test of ulcer. A recent report by Emery and Monroe<sup>23</sup> based on experience in 1,435 cases stated that their results were satisfactory with the "complete Sippy regimen" in 90 per cent of the cases, with the "partial Sippy" in 87 per cent, and with the "five feedings plus alkali schedule" in 82 per cent. These observers drew the conclusion "that none of the present methods of treatment do more than assist in the induction of remission, no matter how strict the medical schedule or how radical the operation."

The results in our histidine series are not quite as good as those in the control series on the less drastic ambulatory, diet-alkali regimen: 73.2 per cent and 78.4 per cent, respectively, showed symptomatic relief. The time consumed and the expense to the patient are much greater with histidine treatment than with the diet-alkali therapy. The frequency of relapses in both series suggests that histidine therapy in peptic ulcer is but another means of inducing a remission. In its favor it may be said that histidine appears to be harmless in the quantity administered, although Newburgh and Marsh<sup>24</sup> have shown that under certain conditions it may have a toxic effect on the kidney.

#### SUMMARY AND CONCLUSIONS

A series of forty-one selected patients with acute symptoms and radiologic signs of active peptic ulcer were treated with intramuscular injections of histidine hydrochloride (from twenty to twenty-four injections each). A crater was demonstrated radiographically in thirty of the forty-one patients. The previous diets of the patients were not changed and all but three of them were kept ambulatory. The immediate response to this therapy was fairly uniform and prompt. Thirty of the patients were relieved of their symptoms at or before the conclusion of the treatment. Fourteen of this asymptomatic group showed radiologic evidence of a healed ulcer, whereas twelve showed a crater still present. Eleven showed no improvement symptomatically or radiographically.

The period of observation varied from six months to one year; thirty-two patients have been under observation for ten months. At the present time thirteen are still symptom free and twenty-six have had one or more relapses. Of the twelve rendered symptom free but in whom a crater persisted, only three have remained symptom free, whereas of the fourteen rendered symptom free and in whom no crater could be demonstrated after treatment, ten have remained asymptomatic.

A second or control group of forty selected patients with acute symptoms and radiologic signs of active peptic ulcer (a crater was demonstrated radiologically in thirty-five) were treated with the usual ambulatory, diet-alkali ulcer regimen. At the end of the first four weeks of treatment, or period corresponding to the completion of treatment in the histidine group, thirty-one were symptom free. The period of observations varied from ten months to one year. At the present time sixteen have remained symptom free, whereas twenty-four have had one or more relapses. These figures correspond fairly closely to those in the literature.

The symptomatic and radiologic response of the patients in the histidine series was not quite as good as that in the diet-alkali regimen series, in either the initial or the sustained effects.

Symptomatic relief with a persistent crater is almost equally common to the two groups, as is a relapse of symptoms. The incidence of relapse is highest in the group rendered asymptomatic but with persistent crater.

Demonstration of a crater establishes a criterion by which a therapeutic substance may be tested, and it also affords a prognostic sign following any form of ulcer therapy.

The clinical improvement succeeding histidine hydrochloride therapy in acute peptic ulcer appears to be symptomatic and transient.

24 Newburgh and Marsh cited by Mitchell and Hamilton.<sup>11</sup>

Chronicity and rhythmicity is a characteristic feature of peptic ulcer. Histidine appears to have no effect other than to alter the rhythm slightly.

Histidine hydrochloride showed no constant effect on the hydrochloric acid secretion in our series.

Histidine hydrochloride in the quantity used appears to be harmless.

The therapeutic indications for histidine in the treatment of peptic ulcer are necessarily limited. The extravagant claims that have been made for this substance are unwarranted.

## REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT  
PAUL NICHOLAS LEECH, Secretary

### LAROSTIDIN 'ROCHE' NOT ACCEPTABLE FOR N N R

In the latter part of 1934 and in 1935 the medical profession was deluged with propaganda for 'Unquestionably the most notable advance in the medical treatment of Gastric and Duodenal Ulcer,' Larostidin 'Roche.' According to the advertising, this is a 4 per cent solution of *laevo*-histidine-monohydrochloride in an isotonic medium.

Hoffmann-La Roche, Inc., advanced such claims as

After approximately 24 injections radiologic findings become negative and the patient may be discharged from treatment.

As injection treatment which means  
no surgical intervention  
no hospitalization  
*except possibly in hemorrhage cases*  
no unusual rigid dietary regimen  
no interference with everyday routine  
prompt relief of symptoms

Larostidin Roche affords the physician a new means of combating peptic ulcer—a treatment which for speed and effectiveness surpasses the usual palliative measures.

These claims are selected at random from the large volume of advertising that has accumulated in the Council office.

Although there were some favorable reports, with which some of the claims were consonant, the Council questioned them and initiated a series of experiments to determine the usefulness of histidine hydrochloride and Larostidin Roche in treating gastric and duodenal ulcer as compared with the diet-alkali regimen. The results of this investigation are reported in this issue of THE JOURNAL (Martin K. A. "Histidine versus Diet and Alkalis in Treatment of Peptic Ulcer," p. 1468). Of the forty-one patients who were the subject of Martin's report as treated by the injection method twenty-eight were given Larostidin and the remaining thirteen received a specially prepared solution of histidine monohydrochloride and sodium chloride comparable with the composition of Larostidin Roche. No difference in response to these two preparations was noted by the investigator. Controls with diet-alkali series were also used. The investigator reported that the symptomatic and radiologic response of forty-one patients in the injection series was not quite so good as that of the forty control patients in the diet-alkali series, in either the initial or the sustained effects.

A careful reading of the results of the investigation indicates that many of the Hoffmann-La Roche claims for Larostidin are enthusiastic beyond the bounds of permissible optimism and are unsupported—and even contradicted—by this series of experiments. As a result of its consideration of the paper of Martin and others however the Council concluded that although there is at present insufficient clinical evidence for its evaluation histidine hydrochloride shows promise of possible usefulness in the treatment of gastric and duodenal ulcer. The Council sponsored publication of Dr. Martin's paper to serve in the manner of a preliminary report.

The Council declared Larostidin (Hoffmann-La Roche, Inc.) not acceptable for New and Nonofficial Remedies, because it is marketed with unwarranted therapeutic claims and voted to postpone further consideration of histidine monohydrochloride until adequate clinical evidence of its therapeutic usefulness is available.

## Committee on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BING, Secretary

### CELLU BRAND TIPS OF ASPARAGUS, WATER PACKED

*Distributor*—Chicago Dietetic Supply House, Inc., Chicago

*Packer*—L. H. Schlecht, Rossville, Ill.

*Description*—Canned green asparagus tips packed in water.

*Manufacture*—Selected green asparagus tips are harvested at the proper degree of maturity, cut to standard lengths, sorted by hand for size, cleaned by spraying with water under pressure, blanched, cooled and hand packed in cans. The cans are filled with boiling water, sealed and processed.

*Analysis* (submitted by distributor)—

	per cent
Moisture	93.8
Total solids	6.2
Ash	0.9
Fat (ether extract)	0.1
Protein (N $\times$ 6.25)	1.7
Crude fiber	0.6
Starch (diastase method)	2.2
Carbohydrates other than crude fiber (by difference)	2.9

*Calories*—0.2 per gram, 6 per ounce.

*Claims of Manufacturer*—Choice quality green asparagus tips packed without added sugar or salt. For use in special diets in which sugar or salt is proscribed or in quantitative diets of calculated composition.

### TRU-LI-PURE BRAND PASTEURIZED HOMOGENIZED MILK

*Manufacturer*—Nashville Pure Milk Company, Nashville, Tenn.

*Description*—Bottled, pasteurized homogenized milk.

*Manufacture*—Milk obtained from tuberculin tested cows under government and company inspection is regularly tested for bacteria, sediment, nonfat solids, acidity and temperature. Milk that passes the test is filtered, heated to 54 C, homogenized at 3,000 pounds pressure, pasteurized by the standard holding method (62-63 C for thirty minutes), cooled automatically, filled into bottles and capped.

*Analysis*—Standardized to contain not less than 4.1 per cent of milk-fat.

*Claims of Manufacturer*—The cream does not separate. The curd formed in the stomach is softer and more readily digestible than that from unhomogenized milk.

### CARNATION COOK BOOK

*Sponsor*—Carnation Company, Milwaukee.

An extensively illustrated Cook Book prepared by the Home Economics Department of the Carnation Company and the Erwin Wasey & Company advertising agency, Chicago. Contains brief introductory discussion of the composition, nutritive value, digestibility and use in cooking and in children's and infants' diets of Carnation milk. Special menus and recipes for use in diets of older children and invalids. Menus for special occasions and recipes for typical national dishes are included.

HEINZ BRAND STRAINED APRICOTS  
AND APPLESAUCE*Manufacturer*—H J Heinz Company, Pittsburgh*Description*—Canned mixture of strained apricots and apples retaining in high degree the natural vitamins and minerals*Manufacture*—Selected fully ripened apricots are sorted, pitted trimmed and steamed. Well ripened apples are mechanically peeled, hand trimmed cut and steamed. In an atmosphere of steam, two parts of apricots and one part of apples by weight are mixed, comminuted, strained—sugar may be added to maintain uniform sweetness—vacuumized and filled into special enamel lined cans, which are sealed under vacuum and processed

<i>Analysis</i> (submitted by manufacturer) —	per cent

Fat (ether extract)	7.8
Protein (N × 6.38)	6.9
Lactose (by difference)	10.4

*Calories*—1.4 per gram 40 per ounce*Claims of Manufacturer*—See announcement on the advertising of the Evaporated Milk Association (THE JOURNAL Dec 19, 1931, p 1890)ADVERTISING LEAFLET SIMPLIFIED  
INFANT FEEDING'

(FOR PHYSICIANS ONLY)

*Sponsor*—Carnation Company, Milwaukee*Description*—Advertising leaflet prepared by Erwin Wasey & Company, advertising agency, for the Carnation Company for distribution to physicians. Contains discussion of advantages of evaporated milk for infant feeding, methods of irradiation chemical composition of irradiated Carnation milk, antirachitic potency of irradiated milk, effect of the processes of evaporation and irradiation on other vitamins of milk, chemical changes resulting from evaporation and claims accepted by the Committee on Foods for irradiated evaporated milks. Specific directions for feeding irradiated Carnation milk to normal infants and to infants presenting special feeding problems are included. Future editions of the booklet will contain statements of vitamin D unitage and cod liver oil equivalence per fluidounce of irradiated Carnation milk.

## ARIZ-SWEET BRAND GRAPEFRUIT JUICE

*Manufacturer*—Ariz-Sweet Grapefruit Growers, Ltd, Peoria, Ariz*Description*—Canned Arizona grapefruit juice, retaining in high degree the original vitamin C content*Manufacture*—Tree-ripened fruit, picked at a definite stage of maturity, under laboratory control, is cleaned, sorted, thoroughly washed, again sorted, and automatically halved. The juice, extracted by light manual pressure on grapefruit halves in contact with revolving burrs, is strained, heated to 32 C, deaerated under vacuum, flash pasteurized, filled into cans and vacuum sealed

<i>Analysis</i> (submitted by manufacturer) —	per cent
Moisture	89.3
Total solids	10.7
Ash	0.5
Fat (ether extract)	0.1
Protein (N × 6.25)	0.5
Crude fiber	0.1

Sucrose	1.0
Carbohydrates other than crude fiber (by difference)	9.5
Acidity as citric acid	1.3

*Calories*—0.4 per gram 11 per ounce*Vitamins*—Chemical titration shows an average cevitic acid (ascorbic acid) content of 0.4 mg per cubic centimeter, 11.8 mg per fluidounce, equivalent to approximately 17 Sherman La Mer units of vitamin C per fluidounce. The analysis shows practically no reduction of vitamin C in the canned product*Claims of Manufacturer*—Intended for all dietary and table uses of grapefruit juices

## HORMEL BRAND CORNED BEEF HASH

*Manufacturer*—Geo A Hormel & Company, Austin, Minn*Description*—Canned corned beef hash, cooked potatoes, corned beef, and onion, seasoned with salt, sugar and pepper*Manufacture*—Fresh chuck beef, United States inspected and passed by the Department of Agriculture, is trimmed of gristle and excess fat, cut in small pieces, seasoned with salt and sugar, mixed with saltpeter and nitrite to preserve the red color of the meat, and cured in salt brine. Saltpeter and nitrite are largely removed when the cured meat is later drained, covered with hot water and boiled for five minutes, again drained and ground. Partially cooked, diced potatoes (mechanically peeled and hand eyed) and peeled, washed and ground white onions are added in formula proportions. The mixture is heated automatically packed in cans, sealed and heat processed

<i>Analysis</i> (submitted by manufacturer) —	per cent

# MEDICAL LICENSURE STATISTICS FOR 1935

ANNUAL PRESENTATION OF LICENSURE STATISTICS BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

The report presented herewith for the year 1935 deals with statistics regarding (a) medical licensing boards of the United States, including the District of Columbia and territories and possessions of the United States, (b) boards of examiners in the basic sciences, and (c) the National Board of Medical Examiners. Official reports have been contributed by the officers of the medical licensing boards of all states, the District of Columbia, Alaska, the Canal Zone, Hawaii, Puerto Rico and the Virgin Islands, the homeopathic examining boards of Arkansas, Connecticut, Delaware, Louisiana and Maryland, the eclectic board in Arkansas, the ten basic science boards (Arizona, Arkansas, Connecticut, District of Columbia, Iowa, Minnesota, Nebraska, Oregon, Washington and Wisconsin), and the National Board of Medical Examiners. The homeopathic boards of Arkansas and Louisiana and the eclectic board in Arkansas did not license any one during the year. Acknowledgment is tendered the officers of the foregoing boards for their ready cooperation and the complete reports they have furnished.

The data supplied were also entered in the biographic file of physicians and others maintained by the American Medical Association, thus serving a dual purpose. Many state licensing boards get in touch with the American Medical Association for verification of biographic data and other claims before granting a license or permission to take the licensing examination. This service is available to all licensing boards.

The tables showing medical licensing board results include figures regarding the number of candidates for medical licensure in 1935, the number licensed and the number added to the profession.

## LICENTIATES

The first table shown contains figures on the number of licenses issued in the various states, territories and possessions during the year. There were 7,887 licenses issued, 5,707 on the basis of examination and 2,180 by endorsement of credentials. In several states (table 7) the internship is a requisite for practice, but a physician is permitted to take the examination and if successful his license is withheld until completion of his internship. Licenses are also withheld for lack of citizenship or minor technicalities. The figures, therefore, for those licensed after examination include many who were examined in 1934 and even a few in previous years. New York issued the largest number of licenses, 1,274, Illinois and Pennsylvania each issued 525, California 472, Ohio 416, Texas 319 and New Jersey 318. A comparison with similar figures for 1934 indicates that New York issued sixteen fewer licenses and New Jersey fourteen fewer in 1935, while Illinois licensed 67 more and Pennsylvania 5, California 54, Ohio 19 and Texas 48 more.

Four states issued between 200 and 300 licenses and fourteen between 100 and 200. Twenty-four states, Alaska, Hawaii, Puerto Rico and the Virgin Islands, licensed less than 100. Only one was licensed by examination in New Mexico. Florida grants licenses only on the basis of examination. Massachusetts and Rhode Island have no reciprocity privileges but endorse

diplomates of the National Board of Medical Examiners. The total number licensed, 7,887, was 157 more than in 1934. This figure, however, does not represent 7,887 individuals since several have been licensed in more than one state during the year. Nor does it represent additions to the medical profession at large since the 2,180 licensed by endorsement, with the exception of those licensed in New York on the basis of foreign credentials, have migrated from other states. Table 5 shows how many of those licensed were never before registered and therefore represent the number added to the medical profession.

## TOTAL EXAMINED

In table 2 are included figures referring to those examined for medical licensure by individual states throughout the year, giving the number who passed and failed in each state. There were 6,426 examined of whom 5,841 passed and 585 failed, representing graduates from sixty-seven approved medical schools in the United States and nine in Canada, seventy-seven medical schools of other countries, twenty medical schools now extinct, nine unapproved institutions and

(CONTINUED FROM PAGE 1475)

several osteopathic colleges. Four undergraduates also were examined. Osteopaths granted the privilege to practice medicine, surgery or both by the medical board are included in these statistics. There were 5,511 graduates of approved medical schools in the United States examined, of whom 4 per cent failed, 112 graduates of approved Canadian medical schools, 17.9 per cent of whom failed, 437 graduates of schools outside the United States and Canada with 30.9 per cent failures, twenty-six who graduated from schools now extinct with 46.2 per cent of failures, and 340 from unapproved and osteopathic schools, of whom 57.9 per cent failed. These 340 candidates represented seventy-nine graduates of osteopathic schools, of whom twenty-seven passed and fifty-two, 65.8 per cent, failed, 257 graduates of unapproved schools, of whom 114 passed and 143, 55.6 per cent, failed, four undergraduates were examined, two of whom passed, one each in Kentucky and Oklahoma and two failed, one each in Mississippi and New York. The undergraduates in Kentucky and Oklahoma were granted a license limiting practice to a remote district. Mississippi examined one candidate by a special act of the legislature. Graduates of osteopathic schools were examined in Colorado, Connecticut, Massachusetts, New Jersey and Texas, while graduates of unapproved schools were examined in California, Florida, Illinois, Indiana, Massachusetts, Missouri, Ohio, Rhode Island, South Dakota and Hawaii. Illinois registered sixty-seven, Massachusetts twenty-six and Ohio sixteen practitioners of the latter group.

The largest number of graduates of any one school was 163 from Northwestern University Medical School, who were examined in thirty-two states, and the University of Illinois College of Medicine, also 163, examined in twelve states. The next highest number of

graduates from any one school was Rush Medical College, which had 160 graduates examined in twenty-six states. The New York Homeopathic Medical College and Flower Hospital and Boston University School of Medicine had the highest percentage of failures in the United States, 22.1 per cent and 20.8 per cent, respectively. Graduates of Northwestern University Medical School were examined in thirty-two, the University of Pennsylvania School of Medicine in twenty-nine, Rush Medical College in twenty-six and Harvard University Medical School in twenty-five states. From these statistics it might be inferred that these schools educate more nonresidents than do other schools. All the graduates of Albany Medical College, fourteen, were examined in New York. None failed. Graduates of the University of Southern California School of Medicine were examined in two states, and graduates of Ohio State University College of Medicine and the University of Pittsburgh School of Medicine in three states. The one eclectic board in existence, in Arkansas, did not examine any candidates. Canadian graduates took the test in twenty-four states. The greatest number, thirty-eight, represented McGill University Faculty of Medicine, who were examined in fourteen states, twenty-four graduates of the University of Toronto Faculty of Medicine were examined in twelve states and eighteen graduates of Queen's University Faculty of Medicine were examined in eight states. Two graduates of the University of Montreal Faculty of Medicine were examined and failed. The next highest percentage of failures was 75, representing Laval University Faculty of Medicine. The following fifteen schools had no failures before state licensing boards: Stanford University School of Medicine, University of Colorado School of Medicine, School of Medicine of the Division of the Biological Sciences of the University

TABLE 4—Physicians Licensed by Reciprocity and Endorsement—1935

[illegible]

**Alaska Hawaii Puerto Rico Virgin Islands**

(CONTINUED FROM PAGE 1479)

132, Texas fifth with 118 and Illinois sixth with 101. All other states licensed fewer than 100. The largest group representing the same type of credentials were the 442 diplomates of the National Board of Medical Examiners, the next greatest number (126) came from Tennessee, Illinois was third with 123, New York was fourth with 118, and Maryland was fifth with 101. Only 118 New York licenses were endorsed during the year, while 395 were licensed on the basis of credentials. Of the latter, sixty-nine were registered on the basis of foreign licenses or diplomas giving the right to practice in the country in which issued.

Twelve physicians were licensed on the basis of Canadian credentials (both provincial and dominion) in four states: Arizona one, Maryland one, New York eight and Vermont two. New York was the only state in which physicians were registered by endorsement of European credentials. Sixty-nine were so licensed representing the following countries: Austria one, England two, France one, Germany fifty-nine, Hungary one, Ireland one, Italy two, Latvia one and Netherlands one. Two physicians were registered in California by the endorsement of certificates from Hawaii and three in New York on the basis of licenses issued in Puerto Rico.

One candidate was licensed by the homeopathic board in Maryland.

Not included in the table are fifteen osteopaths licensed by the board of medical examiners in two states, namely, thirteen granted the right to practice medicine and surgery in Texas, and two permitted the privilege of practicing surgery in Wyoming.

Diplomates of the National Board of Medical Examiners were registered in thirty-nine states, Alaska and Hawaii.

Illinois licentiates were registered in thirty states, while the state that had the highest number of its licenses endorsed, Tennessee, had its 126 licentiates registered in twenty-nine states; seventeen went to New York State. New York had the greatest number of its licentiates registered in any one state: forty-seven, who were given the right to practice in New Jersey, forty-two licentiates of Maryland went to New York State. Alabama, Arizona, Connecticut, Delaware, District of Columbia, Florida, Idaho, Maine, Mississippi, Montana, Nevada, New Hampshire, North Dakota, Rhode Island, South Dakota, Washington, Wyoming, Hawaii and Puerto Rico had less than ten of their licentiates endorsed to other states and New Mexico had none.

In table 3, the 2,165 physicians and 15 osteopaths registered by reciprocity and endorsement are recorded by school of graduation and state or territory where licensed. All of the existing United States medical schools and seven of the nine Canadian schools were represented. The largest number of graduates of any one school were from Harvard University Medical School 96, the University of Michigan Medical School had 67 registered by this method. Rush Medical College 64, the University of Illinois College of Medicine and the University of Tennessee College of Medicine 59 each. Northwestern University Medical School and Johns Hopkins University School of Medicine 57 each. Graduates of 47 foreign medical faculties, 47 extinct medical schools and 1 unapproved institution were licensed without examination. Thirteen osteopaths were granted the right to practice medicine and surgery in Texas and two permitted the privilege of practicing surgery in Wyoming. There were 111 graduates of

foreign medical faculties registered, 71 from extinct medical schools and one graduate of an unapproved institution.

## CANDIDATES ADDED TO THE PROFESSION

In table 5 are recorded the number of candidates added to the profession during 1935. The number represents candidates examined in 1935 and licensed, also those examined in previous years whose licenses were withheld and issued in 1935, those certified on the basis of the certificate of the National Board of Medical Examiners, government services, Canadian and foreign credentials, and miscellaneous. In the main they represent recent graduates. Altogether, 5,500 were

added to the profession as contrasted with approximately 4,000, the number removed by death in 1935. These figures indicate that at least 1,500 have been added to the already overcrowded medical profession. It is assumed that by far the great majority of those licensed are in practice. It is interesting to note that of 7,887 licenses issued throughout the year, 5,500, 69.7 per cent, are actual additions to the medical profession. The largest number added to the profession was in New York 1,022, Pennsylvania added 439 and Illinois 418, Nevada, New Mexico and Wyoming added two. In 1934 there were 5,451 added to the profession. Forty-nine more were added in 1935. Of the figure for 1935, 5,090 were licensed after examination and 410 by endorsement of credentials representing principally those who presented the certificate of the National Board of Medical Examiners.

STATE REQUIREMENTS OF PRELIMINARY  
EDUCATION

The minimum requirement of preliminary education exacted by the Council on Medical Education and Hospitals since 1918 has been two years of college work. There are still eight states, however, which have not revised or amended their statutes to conform with this prerequisite, although these same states, with possibly

one or two exceptions, do not license other than graduates of approved schools. Table 6 records the pre-medical training required in each state.

## REQUIRED INTERNSHIP

Since 1914 seventeen states, Alaska and the District of Columbia have required that applicants for licensure possess a hospital internship. The first state exacting the internship was Pennsylvania and the last one Ver-

TABLE 7—Internship Required by Medical Licensing Boards

mont, affecting the graduates of 1934 and thereafter. A list of the states and others demanding the internship with the effective dates are shown in table 7.

## CANDIDATES EXAMINED FROM 1931 TO 1935 INCLUSIVE

In table 8 are listed the number of candidates examined in the various states, territories and possessions in the last five years, 1931-1935 inclusive, showing those who passed and failed. In this period New York licensed 4,015 candidates, Pennsylvania 2,263, Illinois 1,885, California 1,539, Ohio 1,370, Michigan 1,141 and Massachusetts 1,043. All other states licensed less than 1,000. Thirty-one states licensed less than 500 and eleven states less than 100. The smallest number (51) were examined in New Mexico. The percentage of candidates who failed in the examinations in the past five years is given in the last column. The proportion of failures in all states has increased from 6.2 per cent in 1931 to 9.1 per cent in 1935. In the five year period, 44.1 per cent of the applicants failed in Massachusetts. The high percentage in this state is due to the fact that by law the licensing board is required to admit to its examination the graduates of

unapproved schools, many of whom repeatedly fail. The next highest proportion of failures was in New York with 17.6 per cent. The comparatively high percentage in this state is occasioned by the fact that New York admits a great many graduates of foreign medical schools to its licensing examination. Delaware had 17.1 per cent failures, Nevada 16.7 per cent, Connecticut 14.5 per cent and Florida 12.9 per cent. Florida has no reciprocal relations with any state, all candidates applying being required to take the licensing examinations. Graduates of earlier years, it appears experience difficulty in passing examinations. On the other hand, Alabama, Kansas, Montana, Nebraska, New Hampshire, New Mexico, Oklahoma, South Carolina, South Dakota, Vermont and Washington—eleven states—had no failures. Arkansas, California, Colorado, District of Columbia, Georgia, Idaho, Illinois,

Indiana, Iowa, Kentucky, Louisiana, Maine, Michigan, Minnesota, Mississippi, Missouri, New Jersey, North Carolina, Ohio, Oregon, Pennsylvania, Tennessee, Texas, Utah, Virginia, West Virginia and Wisconsin—twenty-seven states—had less than 5 per cent of failures. A total of 29,500 candidates were examined in the five years from 1931 to 1935 inclusive, of whom 27,194 passed and 2,306 failed, 7.8 per cent. These

figures represent examinations given and not individuals. A candidate who fails more than once in a given year has not been counted twice, but should he fail in one of the succeeding years in another state he is counted in that year also. Likewise, if a candidate fails and later passes, whether in the same or a later year, he is counted as passed and failed. With a total of 2,306 failures for the five year period, it seems likely that there were approximately 27,000 individuals examined. It is to be assumed that the majority of those who fail are later reexamined and licensed in some state. This figure gives a fair estimate of the number of physicians added to the profession each year. Table 5 gives exact totals on this point for the years 1934 and 1935. From this table it can be seen that there has been a gradual increase in the number of physicians examined.

## REGISTRATION 1904-1935

A study of totals and percentages (table 9) for each year beginning with 1904 is of interest. The number (5,841) who passed in 1935 was 221 more than the number who passed in 1934 and only 165 more than in 1904. The number licensed without examination, 2,180, was forty-one more than in 1934. Contrasting these figures with those for 1904 will show the great use being made of this system of licensure. By all methods, 8,021 were registered, 262 more than in 1934. This figure represents the largest number of candidates registered since 1904.

TABLE 9—Registration—1904-1935

Year	All Candidates Examined		Registered Without Written Examination	Total Registered
	Passed	Percentage Failed		
1904	5,676	10.4	990	6,675
1905	5,677	20.7	394	6,081
1906	6,308	20.8	1,490	7,867
1907	5,731	21.2	1,427	7,158

1916	4,145	14.9	1,351	5,496
1917	4,083	14.1	1,360	5,443
1918	3,180	13.2	1,046	4,226
1919	4,074	14.2	2,543	6,617
1920	4,060	15.3	2,534	6,614
1921	4,221	12.4	2,181	6,406
1922	3,737	12.2	2,063	5,600
1923	4,076	14.8	2,398	6,474
1924	4,153	11.8	1,910	6,063
1925	5,415	9.2	1,849	7,294
1926	5,309	7.9	1,979	7,248
1927	4,965	7.2	2,170	7,165
1928	5,084	6.8	2,227	7,311
1929	5,279	5.7	2,416	7,695
1930	5,247	6.2	2,322	7,609
1931	5,228	7.6	2,209	7,469
1932	5,130	7.6	1,875	7,113
1933	5,130	7.6	1,968	7,203
1934	5,190	8.4	2,111	7,759
1935	5,841	9.1	2,180	8,021

Of those examined 9.1 per cent failed in 1935, while 8.4 per cent failed in 1934. While these figures represent those registered in the years given they do not in all states represent the number licensed in a given year. Licenses are withheld in many states as indicated in the text describing table 1.

It will be seen that there has been no constant increase or decrease in the total number of candidates registered from 1904 to 1933 although since 1906 the number licensed without examination has been increasing owing to the universal system of endorsement and the recognition of the certificate of the National Board

of Medical Examiners. The decrease in the number registered in 1918 was due to the sudden withdrawal of physicians and recent graduates from civilian life. Again in 1922 there was a notable reduction, this figure representing the small class that began the study of medicine in 1918. There was, however, a substantial increase in the number registered in 1934 and a still larger increase in 1935, the majority having been by examination. This is probably accounted for by the fact that medical schools are graduating larger classes, 5,035 in 1934 and 5,101 in 1935. The enrolment in

TABLE 10—Source of Physicians Registered—1922-1935

Date	Graduates of Approved Schools		Others		Totals

1933	6,749	93.7	454	6.3	7,203
1934	7,148	91.1	611	7.9	7,759
1935	7,343	91.5	678	8.5	8,021

medical schools for the present college session and subsequent years in many cases has been and will be reduced.

## SOURCE OF PHYSICIANS REGISTERED

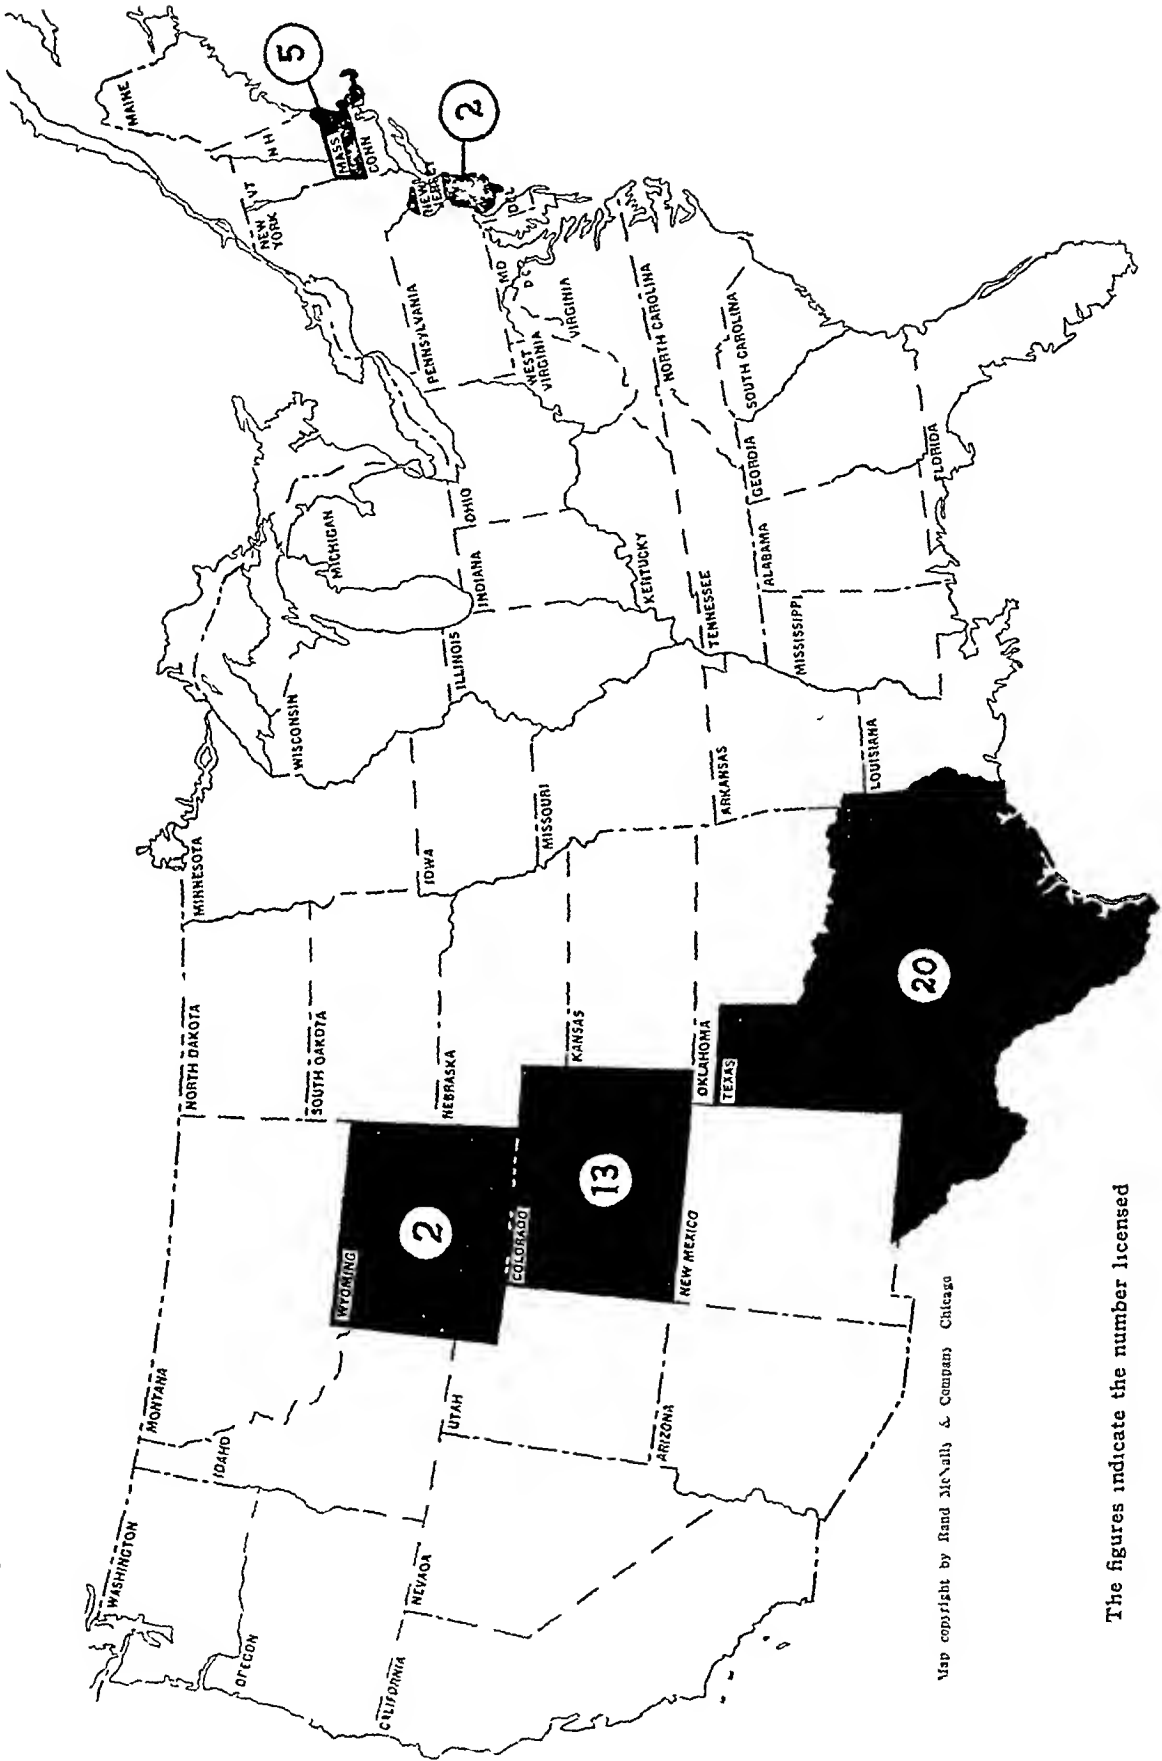

The educational fitness of the individuals registered in the last fourteen years, 1922-1935, is shown in table 10. Of the 8,021 registered by all methods in 1935, 7,343, or 91.5 per cent, graduated from approved medical schools and there were 678, 8.5 per cent, other practitioners registered. In the computation of these figures, all schools rated as class A and B by the Council on Medical Education and Hospitals since 1907 are classified as approved. In the column "Others" are included graduates of institutions prior to 1907, of foreign medical faculties, class C graduates, undergraduates, osteopaths and graduates of schools that have been refused all recognition as medical schools.

## GRADUATES OF OTHER THAN APPROVED MEDICAL SCHOOLS REGISTERED

In table 11 will be noted the total number of graduates of osteopathic colleges and those institutions which have been classified as unapproved, who were registered with or without examination in 1933, 1934 and 1935. In 1935, thirteen states registered 123 graduates of unapproved medical schools and five states registered forty-two osteopaths, granting the latter the privilege of practicing medicine, surgery or both. Of those examined, 114 were graduates of unapproved medical schools and twenty-seven were osteopaths, while two were undergraduates.

The number of unapproved graduates increased by twenty the number registered in 1934. One each was licensed in Florida, Indiana, North Dakota, Rhode Island and South Dakota. Undergraduates were licensed, one each, in Kentucky (limited license) and Oklahoma (by petition to the governor). Missouri and New Mexico licensed two and California three unapproved graduates. The sixteen who were registered in Ohio are graduates of the Eclectic Medical College of Cincinnati an unapproved institution. More recently the school has determined to enroll no new

CHART 1—STATES LICENSING OSTEOPATHS TO PRACTICE MEDICINE, SURGERY OR BOTH—1935

Map copyright by Rand McNally & Company Chicago

The figures indicate the number licensed

students in the school and to discontinue teaching when the present freshman class is graduated

The twenty-six registered in Massachusetts represented two unapproved colleges located in that state and a few elsewhere. This state by law is required to admit to its examination a graduate of any chartered medical school. Sixty-seven graduates of the Chicago Medical School, an unapproved institution, were registered in Illinois. While twenty-six graduates of unapproved schools were registered by examination in Massachusetts, there were 138 failures 84 per cent.

In the three year period shown, 292 graduates of unapproved schools and undergraduates were registered by examination and twenty-two by endorsement.

Forty-two osteopaths were licensed to practice medicine and surgery by examination and endorsement in five states, twenty-seven after examination and fifteen

Osteopaths who are duly registered and licensed to practice osteopathy in the state of New Jersey, who present three years of practice of surgery in a hospital approved by the board of medical examiners, may be admitted to the examination to be licensed to practice medicine and surgery.

The statutes of Texas provide for the issuing of a license to practice medicine only. So far as the statutes indicate, the osteopaths are not restricted in their field of practice.

In Wyoming, osteopaths are granted the right to practice surgery.

In the three year period shown a total of 476 licenses were granted to either graduates of unapproved medical schools or osteopaths. It is to be regretted that such persons are granted the right to practice. The medical profession should be ever watchful and

by endorsement during 1935. These osteopaths were registered in Colorado, Massachusetts, New Jersey, Texas and Wyoming. As shown by table 2, fifty-two osteopaths failed of registration by examination, forty-seven in Massachusetts, one each in Colorado and Texas and three in Connecticut. In this connection the following facts are of interest.

In Colorado osteopaths are admitted to the examination for a license to practice medicine. They have no separate board. The statute of Colorado is silent with respect to the scope of practice authorized by a license issued to osteopaths.

The Connecticut statute provides that any registered osteopath may practice either medicine, surgery or both, as the case may be, after passing a satisfactory examination before the medical examining board.

The Massachusetts statute by definition includes osteopathy in the practice of medicine and does not differentiate the type of license issued to an osteopathic applicant. The medical practice act requires that any applicant for a license to practice must be in possession of a degree of doctor of medicine or its equivalent, from a legally chartered medical school that gives a full four-year course of instruction of not less than thirty-two weeks in each year.

untiring in its efforts to prevent osteopaths and others from gaining the legal right to practice medicine or surgery, for which their training is wholly inadequate. Fewer osteopaths were registered in 1935 than in the previous two years but twenty more graduates of unapproved schools than in 1934.

The results of the medical school survey being conducted by the Council on Medical Education and Hospitals in cooperation with the Association of American Medical Colleges and the Federation of State Medical Boards of the United States should be of assistance to licensing boards.

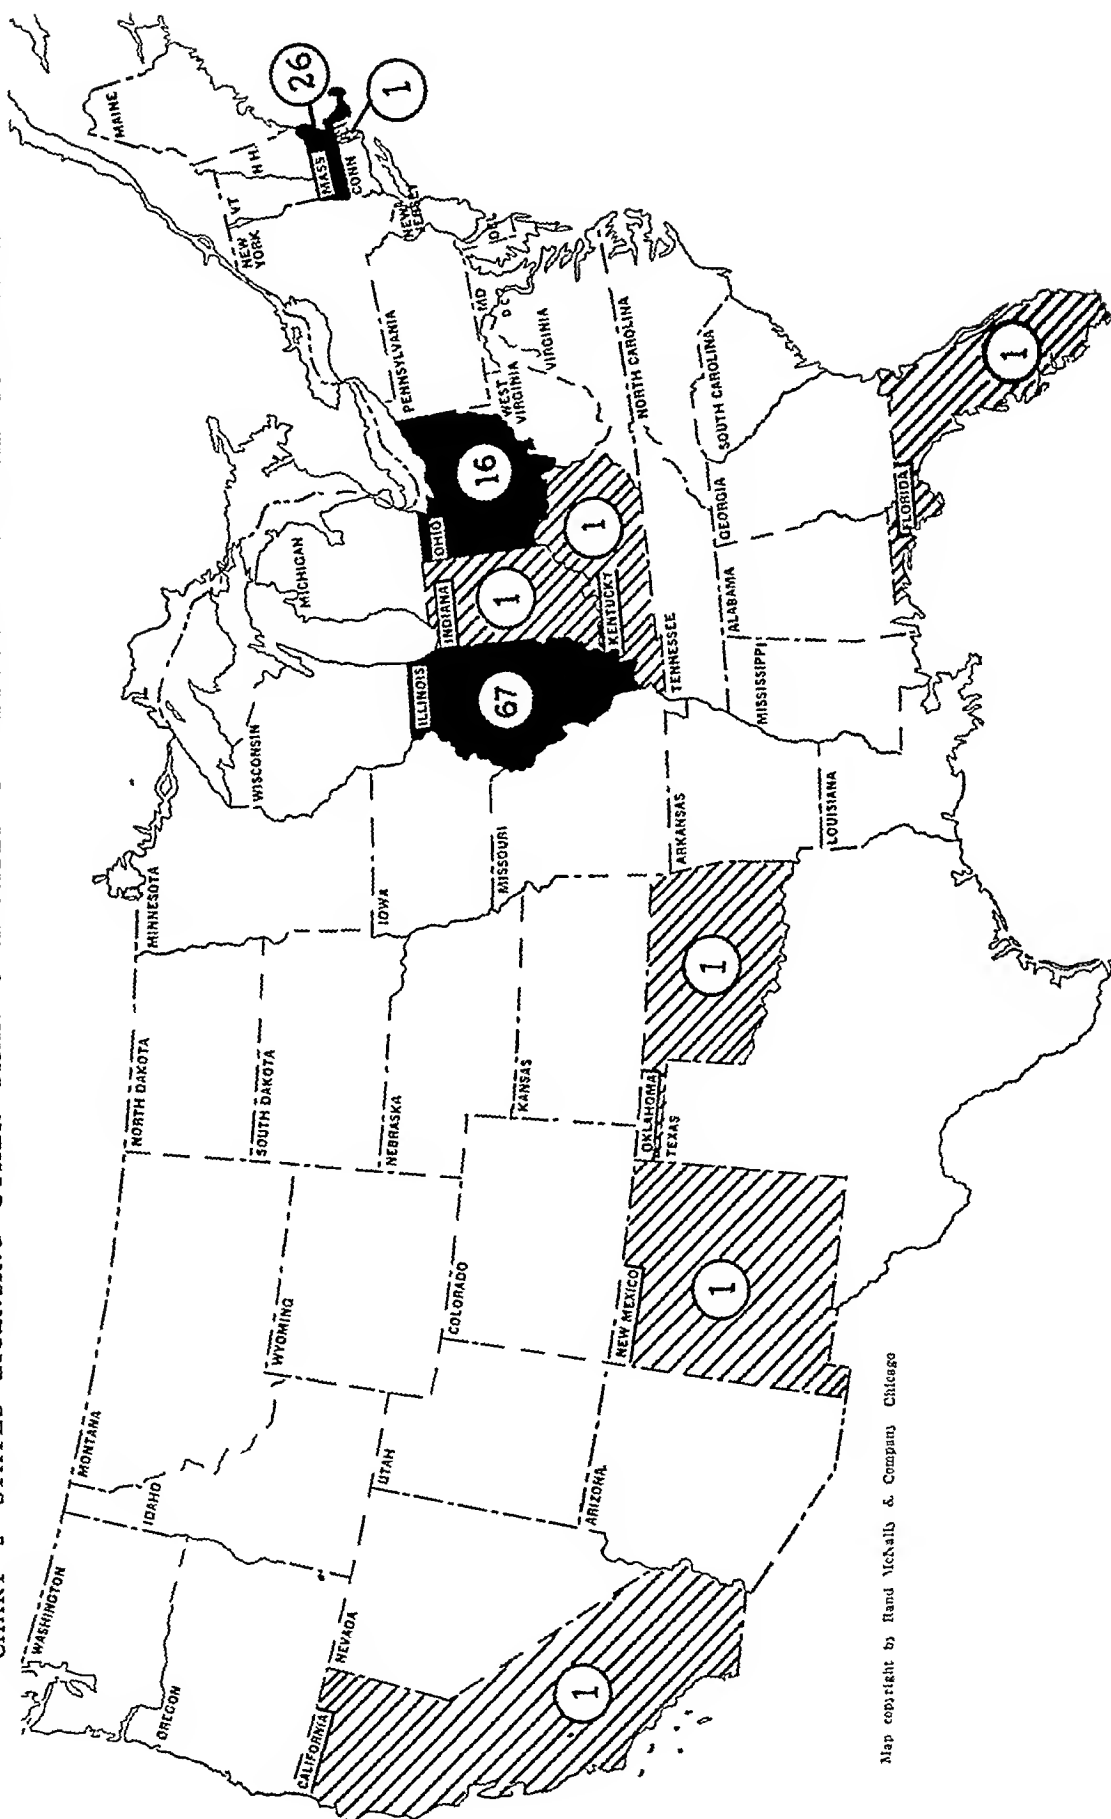

Two charts are presented herewith. Chart 1 shows the states that licensed osteopaths to practice medicine, surgery or both in 1935. Chart 2 indicates by shaded lines those states licensing fewer than five graduates of existing unapproved medical schools and, by a solid area, those licensing more than five such candidates.

#### GRADUATES OF FACULTIES OF MEDICINE ABROAD

A study of the number of Americans pursuing medical courses in Europe has been carried on by the Council since 1931, when it became evident that great numbers of Americans were going to Europe to study. There are now about 1,500 American students studying

(Continued on page 1497)

(CONTINUED FROM PAGE 1487)

abroad who apparently plan to return to the United States to practice. Graduates of faculties of medicine abroad examined for licensure in 1935 are presented in table 13. These represent both American and foreign born physicians. Seventy-seven medical schools of nineteen European, four Latin American and three countries in Asia were represented. There were 437 examined, of whom 302 passed and 30.9 per cent failed. The following tabulation of the number examined in six years and the percentage failing is of interest:

	Number Examined	Passed	Percentage Failed
1930	167	92	44.9
1931	158	91	42.4
1932	182	96	47.3
1933	200	129	35.5
1934	285	170	40.2
1935	437	302	30.9

In addition to the figures given, a number are periodically licensed in New York without examination—by endorsement of their foreign credentials which are equivalent to licensure in this country. In 1935, sixty-nine were so registered in New York.

The increase in the number examined in 1935 represents mostly the Americans who began the study of medicine in 1930. In 1933 the Federation of State Medical Boards adopted a resolution to the effect that no student matriculating in a European medical school subsequent to the academic year of 1932-1933 will be admitted to any state medical licensing examination who does not present satisfactory evidence of premedical education equivalent to the requirements of the Association of American Medical Colleges and the Council on Medical Education and Hospitals, and graduation from a European medical school after four academic years of attendance, and further submits evidence of having satisfactorily passed the examination to obtain a license to practice medicine in the country in which the medical school from which he is graduated is located. This policy of the federation has been made effective by individual action on the part of the state licensing bodies and the National Board of Medical Examiners and will have its desired effect in the future.

In 1934 the Federation of State Medical Boards passed a resolution recommending to its constituent boards that, until adequate information is available, these boards deny graduates of foreign medical schools admission to the licensure examination. However, such candidates as has just been mentioned, were examined in thirty states.

Two years ago the governments of many European countries sent representatives to this country to discuss appropriate measures for dealing with students from the United States. By the raising of entrance requirements, reduction in enrolment and careful scrutinizing of credentials, the number studying abroad should be reduced. During 1935, however, graduates of foreign medical schools were examined in thirty states, the greatest number, 243, having been examined in New York, of whom 35 per cent failed. The next highest figure, thirty-two, were examined in Maryland, of whom 50 per cent failed.

In table 12 are assembled figures showing the standing during the six year period 1930-1935 of the graduates of faculties of medicine outside the United States and Canada admitted to licensing examinations in this country. A similar tabulation is presented for the year 1935. One hundred and thirty schools and eight of the licensing corporations of Great Britain were represented. During the five year period (1930-1934) 1,012 were

examined and 437 in 1935. The largest number examined represented the Regia Università di Napoli, 118, of whom 65.3 per cent failed, the Universität Wien in the five year period was second, seventy, of whom 31.4 per cent failed, while there were fifty-seven from the University of Edinburgh, with 8.8 per cent of failures. A study of the percentage failed is of interest. Here again an attempt has been made to show procedure over a period of years, and if an individual fails or is examined in various states he is recorded as such for a given year.

## BASIC SCIENCE BOARDS

A certificate in the basic sciences is one of the prerequisites for licensure in nine states and the District of Columbia. In the majority of instances this certificate is obtainable after examination. Boards for the certification of candidates functioned during 1935 in Arizona, Arkansas, Connecticut, District of Columbia, Iowa, Minnesota, Nebraska, Oregon, Washington and Wisconsin. The newest addition to this group is that of Iowa, whose basic science board operated for the first time in 1935. Statistics based on the number of candidates certified in 1935, and those who failed to secure this certification, together with the totals for other years, are included in the accompanying tabulations.

In table 1 will be found the subjects in which examinations were conducted in the respective states and the District of Columbia.

TABLE 1—Subjects of Examinations

	Examinations Required in						
	Anat- omy	Bacteri- ology	Chem- istry	Diag- nosis	Hy- giene	Pathol- ogy	Physi- ology
Arizona	+	+	+		+	+	+
Arkansas	+	+	+			+	+
Connecticut	+			+	+	+	+
District of Columbia	+	+	+			+	+
Iowa	+	+	+		+	+	+

Nebraska	+	+	+		+	+	+
Oregon	+		+		+	+	+
Washington	+		+		+	+	+
Wisconsin	+			+		+	+

In table 2 is given the year in which the basic science law in each state was enacted and figures showing the number in the various groups who were examined, passed and failed, in 1935. There were 956 candidates examined by nine boards. Of this number 882 were doctors of medicine and medical students (referred to hereafter as physicians), forty-seven osteopaths, twelve chiropractors, and for fifteen it was not possible to determine what profession they represented. In applying for a basic science certificate, it is not necessary in several of the states to mention the school of practice, but by checking the biographic records of the American Medical Association it has been possible to determine what profession the majority of the candidates represented. The remainder have been placed in the unclassified group. Of the physicians examined, 13.7 per cent failed, 42.6 per cent of the osteopaths failed, 83.3 per cent of the chiropractors and of those unclassified 73.3 per cent failed. There were 761 physicians who passed, twenty-seven osteopaths, two chiropractors and four unclassified. Minnesota examined the largest number, 228, of whom 29 per cent failed, while Wisconsin examined 161 and had 3.7 per cent failures. The District of Columbia, on the other hand, examined only thirty of whom 26.7 per cent failed. Nebraska examined 121 and had 24.8 per cent failures.

Of osteopaths Minnesota examined the highest number, fifteen Washington and Wisconsin each examined ten, Connecticut six, Oregon four and Nebraska two. Chiropractors were examined in Washington (seven) Connecticut (two), while one each was examined in Arizona, Minnesota and Wisconsin. Of the total number of applicants examined, 794 passed and 162 17 per cent, failed.

TABLE 2—Applicants Examined—1935

Totals—Failed		121		20		10		11		162			
Percentage—Failed		13.7		42.6		83.3		73.3					17.0

The number of certificates granted by examination, reciprocity and endorsement are listed in table 3. A total of 794 certificates were granted after examination, of which 761 were issued to physicians, twenty-seven to osteopaths, two to chiropractors and to four who were unclassified. There were ninety-six candidates certified without examination, by reciprocity or endorsement consisting of ninety-two physicians and four osteopaths. Minnesota accepted the greatest number without examination, forty-six all of whom were physicians, while Wisconsin registered twenty-two physicians and four osteopaths.

TABLE 3—Certificates Issued by Examination, Reciprocity and Endorsement—1935

	Examination				Reciprocity and Endorsement				Registered
	Physicians or Medical Students	Osteopaths	Chiropractors	Unclassified	Physicians	Osteopaths	Chiropractors	Unclassified	
Arizona	40	0	0	0	40	0	0	0	30
Arkansas	47	0	0	0	47	0	0	0	36
Connecticut	100	6	1	0	107	0	0	0	107
District of Columbia	22	8	0	0	30	0	0	0	22
Iowa	0	0	0	0	0	0	0	0	0
Minnesota	153	6	0	0	159	46	0	0	205
Nebraska	91	0	0	0	91	12	0	0	103
Oregon	77	4	0	1	82	2	0	0	84
Washington	83	4	1	0	88	0	0	0	88
Wisconsin	148	7	0	1	156	22	4	0	182
Totals	761	21	2	4	794	82	4	0	880

Table 4 shows the number of candidates examined and certified from 1927 to 1935 inclusive. In 1935, 13.7 per cent of physicians failed as compared with 55.4 per cent of other practitioners. In 1928 when five boards were functioning there were 646 physicians examined, of whom sixty or 9.3 per cent failed and fifty-nine other practitioners of whom twenty-eight, or 47.5 per cent failed. In 1935 853 physicians and thirty-seven other practitioners were certified. During the nine year period a total of 5,939 physicians were examined of whom 11.3 per cent failed and 595 other

practitioners of whom 51.6 per cent failed. During this period 784 physicians were certified without examination, while only forty-two other practitioners were so registered.

Altogether, 6,384 certificates have been issued by basic science boards since 1927, of which 6,054 were granted to physicians and 330 to other practitioners. From the high percentage of failures in the other practitioner group it seems apparent that the enforcement of basic science laws affects most seriously this group. Examination of the records of a considerable number of states having basic science laws will show that before such laws were enacted the number of other practitioners appearing for examination and licensure was very considerable and was growing.

TABLE 4—Total Candidates, 1927-1935

Year	Number of Boards	Physicians or Medical Students				Other Practitioners			
		Examined	Passed	Percentage Failed	Endorsement	Examined	Passed	Percentage Failed	Endorsement
1927	5	305	279	26.6	26	305	133	55.4	172
1928	5	646	586	9.3	19	605	59	47.5	0
1929	7	668	610	8.7	75	683	66	33.0	0
1930	7	683	606	11.5	104	710	78	48.0	4
1931	7	680	586	13.8	130	716	107	59.0	0
1932	7	657	590	10.2	93	688	78	44.0	12
1933	8	601	527	12.3	117	644	69	30.0	10
1934	9	815	725	10.0	123	848	51	26.0	11
1935	10	882	761	13.7	62	853	74	33.0	4
Totals		5,270	4,669	11.3	784	6,054	595	51.6	42

The basic science board seems desirable in states having a multiplicity of examining and licensing boards. The object of these boards has been to provide a means of insuring that all candidates seeking authority to care for sick and injured people shall first possess a reasonable knowledge of the sciences fundamental to the healing art.

## NATIONAL BOARD OF MEDICAL EXAMINERS

The National Board of Medical Examiners was organized in 1915 and conducts examinations and awards successful candidates a certificate, which has come to be regarded as an adequate qualification for the practice of medicine. Since 1922 its examination has been given in three parts, parts I and II being written examinations and part III a practical and clinical oral examination. Data are presented in the following paragraphs regarding the examination and the issuance of certificates to the latter group and include tables enumerating the results of examinations in parts I, II and III for each calendar year, excluding duplications, and also of those certified or failing of certification. Figures taken from compilations not reproduced here are also discussed. Similar data have been presented in the State Board Number of THE JOURNAL for eighteen years.

Four examinations were held in parts I and II during 1935 at which 1,264 and 689, respectively, were examined. In part I, 785 passed and 69, 8.1 per cent, failed, while in part II, 620 passed and 69, 10.0 per cent, failed. There were 410 who took incomplete examinations in part I. This examination is arranged for candidates taking part I at the end of their second medical year, who are attending schools the third year curriculum of which includes courses in one or two sub-

jects of part I. The subjects thus postponed may be taken at any examination period after the candidate has completed them in his medical school. Also listed under this heading are those who wish to spend some additional time on one or two subjects. Incomplete examinations were not included when computing percentages, since they represent neither a candidate eligible for certification nor a failure.

Since 1922, a total of 12,943 examinations have been given in part I and 6,634 in part II. From 1922 to 1935 inclusive, 8,302 individuals have been successful in passing part I, and 5,915 in passing part II. These figures include 3,293 who took incomplete examinations in part I and thirty-three in part II. The figures cover the totals of each examination given during a calendar year and include some who fail and are reexamined during the same year and also some who pass parts I and II in the same year. Therefore they represent examinations conducted rather than individuals examined. In the fourteen year period since 1922 there were 1,348 failures in part I, 14.0 per cent, and 686 in part II, 10.4 per cent.

The results of examinations in part III for the fourteen year period 1922 to 1935 inclusive are presented in table 1. In 1935, 598 were examined as compared with twenty-eight in 1922. There has been a steady

TABLE 1—Examinations in Part III

Examinations of	Total Examined	Passed	Failed	Percentage Failed
1922	23	23	0	0.0
1923	76	70	1	1.3
1924	120	114	6	5.0
1925	217	206	11	5.1
1926	255	243	12	4.7
1927	294	272	22	7.5
1928	322	306	16	5.0
1929	371	336	15	4.0
1930	419	400	19	4.5
1931	477	419	18	4.1
1932	549	521	28	5.1
1933	532	527	5	0.9
1934	531	545	3	0.6
1935	598	578	20	3.3
Totals	4,799	4,573	226	4.7

increase of approximately fifty each year since 1925. Of the number examined in 1935, twenty, or 3.3 per cent failed. The highest percentage of failures was in 1927 when 294 were examined and twenty-two, 7.5 per cent, failed. During 1935, 578 were granted certificates. In fourteen years, 4,799 were examined, of whom 4,573 were granted certificates and 226, 4.7 per cent failed. Here again a candidate having failed may subsequently receive a certificate. Incomplete examinations were taken for diverse reasons in 1935 by forty-eight candidates. No mention is made of these in the statistics.

From 1915 when the board was organized, up to and including 1935, 4,840 certificates have been granted.

The figures in table 2 represent the number of individuals examined during any one year. The classification as passed or failed, in cases in which more than one examination has been taken in a given year, was based on the results of the last examination during the year in question. For example, if in 1935 a candidate passed part I but later failed part II, he is listed as having failed. Taking this into consideration, there were 2,367 who took the examination of the National Board of Medical Examiners during 1935 as compared with 525 in 1922. A total of 17,370 passed one or more of the examinations in the fourteen years shown and 2,008 or 10.4 per cent failed. Incomplete exami-

nations have been taken by 3,137 individuals, many of whom have since received certificates.

Diplomates licensed on the basis of their credentials in the United States have increased from two in 1917 to 442 in 1935, 3,021 having been so licensed since the National Board was created. A total of 4,840, however, have received the certificate of the National Board. In 1935, 442 diplomates were registered on the basis of credentials in thirty-nine states and two territories.

The certificate of the National Board of Medical Examiners is granted recognition by the licensing boards of the following forty-three states and four territories:

Alabama	Illinois	Nebraska	Puerto Rico
Alaska	Indiana	Nevada	Rhode Island
Arizona	Iowa	New Hampshire	South Carolina
Arkansas	Kansas	New Jersey	South Dakota
California	Kentucky	New Mexico	Tennessee
Canal Zone	Maine	New York	Utah
Colorado	Maryland	North Carolina	Vermont
Connecticut	Massachusetts	North Dakota	Virginia
Delaware	Minnesota	Ohio	Washington
Georgia	Mississippi	Oklahoma	West Virginia
Hawaii	Missouri	Oregon	Wyoming
Idaho	Montana	Pennsylvania	

Some of these boards, however, have additional requirements.

Diplomates of the National Board of Medical Examiners are admitted to the final examination given by the Conjoint Examining Boards of England and Ireland and the Triple Qualification Board of Scotland. The certificate is also recognized in South Africa, Spain, Syria and Turkey.

Five medical schools now require their students to pass either part I of the National Board examination or parts I and II. Several other schools give their students the option of taking the National Board examination or the school's comprehensive examination. In one or two schools, passing the board's examination in part I excuses the candidate from a portion of the final comprehensive examination given at the end of the fourth year.

Because many graduates of European universities and medical schools are applying for internships in this country, the Council on Medical Education and Hospitals at a meeting in February voted "that when suitable graduates of class A schools of the United States and Canada are not available, hospitals approved

TABLE 2—Parts I, II and III Excluding Duplications

	Total Examined	Passed	Incomplete	Failed	Percent of Failed
1922	525	381	58	86	16.4
1923	775	594	79	102	14.7
1924	978	756	69	153	16.8
1925	1,167	915	50	202	18.1
1926	1,161	930	100	126	11.9

SATURDAY, APRIL 25 1936

## THE STATE BOARD STATISTICS

The annual report on the examination and licensure of physicians in the United States for the year 1935 appears in this issue. The statistical tables and the special summaries show conditions at present and indicate trends over many years. In 1935, 7,887 applicants were licensed, of these, 5,707 were licensed by examination and 2,180 by endorsement of credentials, 5,500 licentiates were added to the medical profession and some 4,000 died. The net gain was about 1,500.

Failures to pass examination seem to be increasing. In the past five years the total number of physicians examined per year has risen from 5,608 to 6,426. The number of failures rose from 348, or 6.2 per cent, to 585, or 9.1 per cent. The number that failed to pass in 1935 was larger than in any year since 1925.

The graduates of unapproved medical schools of recent and previous years were granted examination in several states, conspicuous among which were Illinois, which registered sixty-seven such graduates, Massachusetts twenty-six, and Ohio sixteen.

The requirement of a hospital internship by state boards began in 1914. At the present time nineteen boards have such a requirement. Because many graduates of European universities and medical schools are applying for internships in this country, the Council on Medical Education and Hospitals at a meeting in February voted that 'when suitable graduates of class A schools of the United States and Canada are not available, hospitals approved for intern training may accept graduates of European schools who have passed parts I and II of the examinations of the National Board of Medical Examiners.'

The number of physicians granted licenses to practice medicine and surgery without examination in the states and territories was 2,165. These persons presented to the various licensing boards licenses from other states and foreign countries or the certificate of one of the government services or the National Board of Medical Examiners or other credentials. Florida, Massachusetts and Rhode Island do not have reciprocal or endorsement relations with any state.

## GRANULOCYTOPENIA, MALIGNANT NEUTROPENIA OR AGRANULOCYTOSIS

In 1922 Schultz<sup>1</sup> described a condition of the hematopoietic system characterized by severe leukopenia and the disappearance of granulocytes from the peripheral blood. This was accompanied by a necrotic process of mucous surfaces, principally of the mouth and pharynx, profound sepsis, and death in from two to seven days. The onset of the disease is sudden, with prostration and a rapid rise in temperature, which persists throughout the course. Redness and swelling of the pharyngeal mucous membrane is rapidly followed by deep ulcerations, which are covered with a dirty gray membrane. Only a moderate enlargement of the regional lymph nodes is associated. Examination of the blood reveals characteristic alterations in the leukocytes. Leukopenia and granulocytopenia progress in many cases to a total disappearance of granulocytes from the peripheral blood. The total number of lymphocytes and monocytes may remain normal, be increased or, more often, diminish because of the general diminution in the number of the white cells. Their percentage relationship, however, is always increased at the expense of the disappearing granulocytes. The bone marrow as obtained by puncture or at postmortem is pale. In histologic preparations of the marrow, diminution of morphologic elements is observed with a diminution or total absence of granulopoiesis. The surviving cells belong to the lymphoid type. The megakaryocytes and the erythropoietic cells appear normal. Postmortem studies likewise reveal numerous bacterial emboli obstructing the blood vessels, necrotic processes of the mucous surfaces of the mouth, pharynx, gastro-intestinal tract, liver and spleen, and the absence of suppurative processes. The pathologic alterations described are believed to be due to failing or arrested granulopoietic function of the bone marrow.

This disease has occurred with greatest frequency in the United States and in Germany, where it was first described. It has been seen predominantly in women (from 80 to 90 per cent) of middle age of the better social status and shows a peculiar predilection for members of the medical group.

Three hypotheses were promptly advanced as to the etiology of this condition. The first considered sepsis as the primary cause and the blood changes and the necrotic lesions of mucous membranes as secondary. The second hypothesis considered the characteristic lesions of the mouth and the pharynx the primary lesion, giving rise to sepsis and granulopoietic disturbances. The third hypothesis considered the alterations in the granulopoietic organs the primary and essential cause, and the septic state and the necrotic lesions as the result of loss of the defense mechanism in an organ deprived of its granulocytes. The last hypothesis has been accepted by most investigators,

<sup>1</sup> Schultz, Werner. *Leber eigenartige Hal-erkrankungen*. *Deutsche med. Wchnschr.* 15: 1492 (Nov. 3) 1922.

although the nature of the depressing agent remained largely undetermined. Bacteriologic studies, as well as animal injection experiments, failed to demonstrate a specific organism. Various investigators were able to produce agranulocytic changes followed by sepsis, by administration of toxic substances such as benzene,<sup>2</sup> neoarsphenamine,<sup>3</sup> bismuth compounds and gold preparations. Kracke and Parker<sup>4</sup> collected from the literature reports of 173 cases of agranulocytosis following the ingestion of drugs. Of this group, 153 cases followed the use of aminopyrine. According to these authors, four salts can be incriminated as etiologic factors. These, in the order of their importance, are aminopyrine, dinitrophenol, gold salts and organic arsenic compounds. Endocrine influences and constitutional predisposition, as well as a true allergic response, were advanced to explain why a relatively small number of persons, in view of the wide use of aminopyrine, should react to this drug with damage to the hematopoietic system. The exact mechanism of drug action requires further elucidation.

Since Schultz first described the disease, our concept of it has undergone a number of modifications. The occurrence of symptomatic agranulocytosis, due to a definite cause in each case, suggests that the condition is possibly not an independent clinical entity but a syndrome. In addition to the type in which leukopoiesis alone was disturbed, there were observed types in which there existed a combination of disturbances of leukopoiesis with that of disturbance of erythropoiesis or thrombopoiesis. Types were observed in which granulocytopenia was combined with a grave anemia of the aplastic type, types combined with thrombocytopenia and hemorrhagic diathesis, and, finally, a form of hemorrhagic aleukemia described by Frank in 1925. Many cases exhibit a slow development as well as recurrences. Furthermore, a number of patients have recovered, although the prognosis, especially of the essential variety, remains grave (mortality of about 92 per cent). A favorable prognosis can be predicated on the appearance of eosinophils in the blood, a progressive increase of leukocytes and, in particular, on the appearance of granulocytes of various degrees of maturity of myelocytes and of myeloblasts.

The therapy of the disease is far from satisfactory. Pentnucleotide was introduced in 1929 in the hope that it would stimulate leukocytosis. Jackson<sup>5</sup> believed it to be efficient when given in large enough doses, not less than 40 cc daily. Kracke and Parker did not see any benefit from it. Parenteral administration of liver extracts has favorably influenced the course of the disease, according to recent reports. It is questionable

whether transfusion of blood will have a stimulating effect on leukopoiesis. At the present state of our knowledge it would appear wise to combine all the experimental therapeutic agencies that have been mentioned.

## CHEMISTRY OF VITAMIN E

One by one the physiologically important natural constituents of plant and animal material are yielding their chemical identities to the exhaustive researches of the organic chemist. The preparation in pure form and the identification as a chemical entity of any substance of physiologic significance in the organism has invariably been followed by rapid accumulation of information suggesting its functions in the body. It is only necessary to recall the more recent investigations on cevitamic acid, or vitamin C, as an illustration of this point.

All the well established vitamins, and some of the less definite suggested food accessory factors, have received attention from the chemist. The efforts in some cases have led to the isolation of crystalline substances capable of producing physiologic responses known to be characteristic for the particular vitamin and therefore supporting the conclusion that the isolated material is identical with the vitamin itself. In several instances, for example in the case of vitamins A, B<sub>1</sub>, B<sub>2</sub> (G), C and D, the organic chemist has established, with a considerable degree of certainty, the chemical formulas and structures of the particular vitamin. Relatively less attention has been given by the chemist to vitamin E, the food accessory substance essential to the rat for the normal bearing of the young. However, three laboratories—Evans and his collaborators at the University of California, Olcott and Mattill at the University of Iowa, and Drummond and his group at University College, London—have expended considerable effort in attempts to concentrate, isolate and identify vitamin E. The goal appears to be near at hand.

In a recent communication<sup>1</sup> the California group reports the successful isolation from wheat germ oil of an alcohol having the properties of vitamin E. The material was obtained as an oil, and it exhibited sporadic vitamin E activity in doses of 1 mg. A single dose of 3 mg. permitted the regular production of normal litters under nutritive conditions not ordinarily favoring normal gestation. The investigators propose for this alcohol the name "α-tocopherol," from the roots "tokos" meaning childbirth, "phero" to bear and the ending "ol," indicating an alcohol. Two crystalline derivatives of this physiologically active oil were prepared, and the elemental analyses of these compounds indicate an empirical formula of C<sub>29</sub>H<sub>50</sub>O<sub>2</sub> for the vitamin itself. Two additional alcohols were also obtained as oils from the wheat germ concentrate, each of which proved to be isomeric with α-tocopherol. One

was physiologically inactive, the other appeared to have some vitamin E potency. The isolation of the vitamin itself in crystalline form and establishment of its chemical configuration should give some interesting insight to its role in the organism and to the mechanism of its activity.

### MEDICAL PROGRESS IN THE PHILIPPINES

In 1935 there were in the Philippines a total of 2,901 physicians for an estimated population of about 13,500,000. There was therefore one physician for every 4,700 inhabitants, or about twenty-one physicians per hundred thousand of the population. This compares with 126.6 physicians per hundred thousand of the population in the continental United States. A review of the past and present medical services in the Philippine Islands has recently appeared under the auspices of the local medical society.<sup>1</sup> Medical services are rendered by the Philippine government, private practitioners, private corporations, semigovernmental institutions and the United States government.

One way of measuring the efficiency of medical services is comparison of the mortality rates. This is a crude method and subject to numerous modifying factors, but it does give information. For many years there has been a steady decline in the mortality rates in the islands. From a rate of 39.7 during the Spanish regime it shot up to 50 from 1899 to 1903 and came down to 27.05 in 1904. Since 1904 there has been a gradual decline, except for 1918, and since 1921 it has been below 20 per thousand. This rate compares with a rate of 14.7 for the United States, 40 for China and 28 for Spain. It is still higher than the rate of the Anglo-Saxon countries, but, with the exception of Japan, the lowest of the oriental. It is also lower than the rates of Puerto Rico, Spain and Mexico.

Part of the high death rate has been due to infant mortality, largely infantile beriberi. The effectiveness of the campaign to reduce infant mortality is illustrated by the decrease in the infant death rate from 225 per thousand in 1904 to 146 per thousand in 1933.

Another important fact brought out by this report is the large share of credit due the private practitioners for the improved conditions. Of the 2,901 medical practitioners in the Philippines only about 745 are in the service of the Philippine government and about sixty-eight in the service of the United States government. There has been a considerable increase in the number of medical men in the Philippines so that the average age of the physicians is relatively low (38) and a high percentage are still, therefore, in the prime of life. While this is an advantageous factor, the report clearly shows that there is room for still further increase in the number of physicians and especially for

their better distribution. The number of hospitals also has increased from seventy in 1924 to 147 in 1934.

Fernando, who wrote the report, also points out that the remarkable improvement in health attained during the American regime in the Philippines has occurred with a high degree of cooperation between private practitioners and governmental agencies and that neither compulsory health insurance nor complete government practice of medicine has at any time been necessary. There seems to be no question that this improvement will continue, if judged by the constructive recommendations embodied in the report. The time-tested methods of medical progress are clearly shown not to have outworn their usefulness.

### Current Comment

#### FATE OF INJECTED ALUMINUM

The widespread modern use of cooking utensils made of aluminum has attracted interest in the question of the behavior of this metal in the animal body. As was stated in these columns a short time ago<sup>1</sup> there is no convincing evidence that aluminum in amounts in which it is likely to be consumed as a result of the use of aluminum cooking vessels has a harmful effect on the ordinary consumer, indeed, there is no definite proof of the absorption of this metallic element from the gastro-intestinal tract. However, that a small amount of aluminum gains entrance into the normal animal organism is indicated by the general finding of minute quantities of the element in various tissues. Questions logically arise regarding the fate of aluminum once it enters the animal body. If it is largely excreted, what is the pathway? If it is stored what effects may result from its presence? A number of investigations in which soluble aluminum salts have been injected into animals and subsequent analyses made of the tissues and excreta have been performed in order to answer these questions. In the most recent study of this type<sup>2</sup> a small amount of aluminum, as the chloride, was injected intravenously into dogs for long periods. Analyses of the tissues of these animals demonstrated that a small amount of the injected aluminum was stored, chiefly in the liver and spleen, and to a lesser extent in the kidney. Traces of the metal were present in various other tissues. Apparently most of the substance was promptly excreted in the urine and in the bile. No definite statement concerning toxic reactions in the experimental subjects was made. In another species, the rabbit, the continued intravenous injection of small amounts of aluminum was found to produce a profound anemia and pathologic changes in the kidneys and spleen.<sup>3</sup> Thus far a great mass of available evidence attaches little significance to small amounts of aluminum entering the human body by ingestion.

## Association News

### THE KANSAS CITY SESSION

#### Alumni Dinners

Alumni dinners, in addition to those listed in the Kansas City Number of THE JOURNAL, have been arranged as follows

UNIVERSITY OF MINNESOTA MEDICAL SCHOOL, Wednesday evening, May 13, Parlors A and B Fourth Floor, Kansas City Club, E H Trowbridge, chairman

TULANE UNIVERSITY OF LOUISIANA SCHOOL OF MEDICINE, Wednesday May 13, 6 30 p m, Florentine Room, Kansas City Club, Evan S Connell, chairman

#### Special Train Service to Kansas City

The Chicago, Milwaukee, St Paul and Pacific Railroad announces that the "Southwest Limited," a de luxe, air conditioned train, will leave Chicago from the Union Station daily beginning Sunday, May 10, at 7 30 p m, arriving in Kansas City at 8 a m. This train will carry special sleeping cars for the use of members of the American Medical Association attending the annual session at Kansas City. For reservations please communicate with Mr V L Hitzfeld, Assistant General Agent, Room 711, 100 West Monroe Street, Chicago

#### Association of Military Surgeons of the United States

The Association of Military Surgeons of the United States will have a dinner in the Francis I Room of the Hotel Baltimore on Tuesday, May 12. The speakers at the dinner will be General Robert U Patterson and Colonel Kent Nelson

#### American Board of Dermatology and Syphilology

A dinner for the diplomates of the American Board of Dermatology and Syphilology has been arranged for at the Hotel Kansas Citian on Wednesday, May 13, at 7 p m. Diplomates who have not made reservations are requested to notify at once Dr Charles C Dennie, 1524 Professional Building, Kansas City, Mo

### BROADCASTS FROM THE KANSAS CITY SESSION

Special radio programs will be broadcast from Kansas City during the week of the annual session

#### NATIONAL BROADCASTING COMPANY

The following programs will be delivered over a network of the National Broadcasting Company

May 11, 4 30 p m "Nutrition and the Future of Man," by Dr James S McLester, President of the American Medical Association. Fifteen minutes

May 12, 4 p m Medicine Marching Forward. The regular dramatized program "Your Health" (originating in Chicago), based on papers or exhibits presented at the convention. Thirty minutes

May 13, 12 noon An interview about the Scientific Exhibit with Dr Morris Fishbein. Fifteen minutes

#### COLUMBIA BROADCASTING SYSTEM

The following programs will be broadcast over a network of the Columbia Broadcasting System

May 11, 1 30 p m An interview with one or more distinguished foreign visitors by Dr Morris Fishbein. Subject to be announced. Fifteen minutes

May 15, 2 p m A news broadcast outlining the main events of the convention. Dr W W Bauer. Fifteen minutes

May 15, 8 45 p m Medicine Yesterday and Today. A dramatized program (originating in Chicago), based on papers or exhibits presented at the convention. Thirty minutes

The hour given is central standard time, eastern standard time is one hour later, mountain time one hour earlier, and Pacific time two hours earlier. Daylight saving time in each locality is one hour later

### RADIO BROADCASTS

The American Medical Association broadcasts over WEAF, the Red network instead of the Blue, as formerly, and certain additional stations of the National Broadcasting Company at 5 p m eastern standard time (4 o'clock central standard time, 3 o'clock mountain time, 2 o'clock Pacific time, daylight saving time in each locality is one hour later) each Tuesday, presenting a dramatized program with incidental music under the general theme of "Medical Emergencies and How They Are Met." The title of the program is "Your Health." The program is recognizable by a musical salutation through which the voice of the announcer offers the toast "Ladies and gentlemen, your health!" The theme of the program is repeated each week in the opening announcement, which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night, for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast

**Red Network**—The stations on the Red network of the National Broadcasting Company are WEAF, WEEI, WTIC, WJAR, WTAG, WCSH, KYW, WFBR, WRC, WGY, WBEN, WCAE, WTAM, WWJ, WMAQ, KSD, WHO, WOW, WDAF

**Pacific Network**—The stations on the Pacific network are KGO, KPO, KFI, KGW, KOMO, KHQ, KFSB, KTAR

Network programs are broadcast locally or omitted at the discretion of the local station. The lists indicate stations to which programs are available

The next three programs are as follows

April 28 Infant Care W W Bauer M D

May 5 Maternal Care W W Bauer M D

May 12 Medicine Marching Forward W W Bauer, M D

### ANNUAL CONGRESS ON MEDICAL EDUCATION, MEDICAL LICENSURE AND HOSPITALS

DR FRED MOORE, Des Moines, Iowa, in the Chair

#### COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

Thirty Second Annual Meeting held in Chicago Feb 17 and 18 1936

(Continued from page 1497)

FEBRUARY 18—AFTERNOON

#### Swans Sing Before They Die

DR E P LYON, Minneapolis. I shall speak of some of the problems of medical education which I consider important and which I hope the future may solve. The first concerns the choice and admission of students. This involves a responsibility on the part of college officers which they have rarely sufficiently realized and faced. It predicates decisions on which the whole life and work of young men and women may depend, and in which the future standards of medical practice may be foreshadowed. That the job is not well done is manifest by the large proportion of failures. As a basis for this function we have first the record of the premedical scholarship marks. These come to our desks from some 700 colleges, including every type and grade of institution from the standpoint of facilities, staff and curriculum. The same thing is brought out by the Moss aptitude test. The average percental rank attained by those taking the test in some premedical colleges and universities is well above the mean. The average percental rank in some other colleges is markedly below the average for the country as a whole. This may be due in part to differences in teaching and length of training. But most educators are agreed that the prime factor is selection. Out of this comes the fact that the marking systems of different collegiate institutions are not comparable. The great question emerges. Can we get any better basis for admission than college grades, intelligence tests and interviews, for such as believe in that technique? At Minnesota an all-university committee has worked on this problem for two years. There is a subcommittee for each school and college. That for the medical school consists of three of our professors, several psychologists, ample statistical and clerical

help. An industrial process that recorded a 20 or 25 per cent rejection of imperfect parts in the manufacturing process would certainly be regarded as inefficient. If inevitably some of these imperfect parts slipped by the inspection and appeared in the finished product, managers and owners would be troubled. We medical educators should be concerned. Until we are surer about our raw material, more exacting in our inspections, more clear as to what our product should be the medical profession will average lower than it should in the great field test that goes on day by day in the fight for better health. School examinations need as close scrutiny as our choice of raw materials. We need a new or at least a tested and reliable technic of examination.

What is happening to our material outside college walls? One of the psychologists of our committee raised the question of medical fraternities in a new way. How is the performance of these groups in medical school in comparison with what it ought to be on the basis of premedical grades. Out of this comes the conclusion, that some fraternities do better and some worse than would have been expected. It is disquieting that we may have organizations among our students which actually have the effect of lowering the potential performance of their members.

Another feature which causes concern is the fact that medical education is in general restricted to those who have money. This fact means inevitably that some superior men cannot enter the medical profession and that the average standard is lowered thereby. The problem is real in every line of education. In a study of high school graduates in Minnesota, Dean J. B. Johnson of the Arts College estimates that there are perhaps 300 superior students a year in the high schools of the state who are unable to attend college because of lack of money. Under our system we can suggest nothing better than scholarships with a well organized arrangement for their distribution to the most able candidates. I firmly believe that at present ten million dollars would at no other point create such dividends of medical progress as in the search for and assistance of submerged superior ability.

In general I am favorable to increased requirements. But before the three year premedical course becomes embedded in the requirements of state boards I advocate that an alternative proposal be experimented with by some medical colleges. I would add another year to the medical course itself. I would transfer to the medical curriculum some of the courses now classed as premedical, such as organic chemistry, sociology and psychology. I would leave the minimum entrance requirement at two years of college as now, but the transfer described would permit of a wider sampling of college offerings in the direction of cultural background. I think the added medical year would enable faculties to plan a better balanced medical curriculum. I would begin anatomy, biochemistry, perhaps bacteriology in this year. But I would devote at least half the time to subjects now considered premedical. Psychology, adapted to medical students and thought of as the basis of mental medicine in the same way as anatomy and physiology are basic to physical medicine, would certainly be required and in the medical curriculum. I suggest that the objection of added expense be met by keeping the fee for this year lower than for the other medical years. I suggest further that limits of attendance be not so rigidly enforced and that this preliminary year be the real testing ground of fitness for continued medical study. Those familiar with the Toronto plan will recognize the similarities. The main argument is to secure for students a year earlier the immense motivation that comes from being a real medical student.

The question of overproduction of doctors is of the greatest importance. I contend that there are already too many doctors even if they were properly distributed and even if their services were available to all people neither of which contingencies is true or likely to be true under American conditions. In many years at a dean's desk I have watched the increasing difficulty and discouragement experienced by young doctors in earning a living. To say that the same condition exists in every profession does not help the situation. Last summer I had a conference with Professor Thunberg at Lund, Sweden. He showed me the letter setting the number of new medical students that may be received this year at the

Swedish universities—forty-four at Lund, fifty-six at Uppsala, 100 at Stockholm. "But who," I inquired, "makes the decision?" "The chancellor," replied Dr. Thunberg, "whose name is signed to this letter. We Swedes have confidence in him. He is in touch with all interests, including the medical profession. The accepted principle is to educate only as many doctors as the country needs. The decision of the chancellor is accepted by all." So far as I can see, the American Medical Association has made only a tentative approach to this problem. Let the elder statesmen add to their number such specialists as may be needed, sociologists, educators, population experts. Let them determine the facts. Bring the united wisdom of those interested to bear on the question. I think that the colleges would reduce the number of their medical students if requested to do so by such a commission.

#### Function of the Hospital in the Training of Interns and Residents

DR J. A. CURRAN, New York. This article appeared in THE JOURNAL, March 7, page 753.

#### The Laboratory of Pathology in the Small Hospital

DR HOWARD T. KARSNER, Cleveland. This article appears in full in this issue, page 1445.

#### DISCUSSION

DR A. S. GIORDANO, South Bend, Ind. Adequate laboratory facilities require ample room space. Requests for examinations, delivery of specimens and delivery of reports are time consuming, so that it is imperative that the clinical laboratory be centrally located. A basement or top floor location thus is expensive as well as inconvenient. Should routine laboratory examinations be delegated to interns instead of supervised technicians? My experience leads me to answer no. A well trained technician will render far superior and more uniformly dependable service. However, since it is necessary that interns acquire practical training in laboratory technic, it is recommended that they be required to do only the routine laboratory work on patients in their care, but the technician should check the results. The third point involves a fundamental principle, namely, that the function of the college is to teach and conduct research. The question is, Should teachers of pathology engage in the extracollegiate practice of laboratory medicine? I should like to submit reasons for answering this in the negative. I have the highest regard for the author as a teacher and scientific investigator. The proposed plan, however, would not go far as a universal solution of the problem. This plan has worked satisfactorily in Cleveland, but is not the credit due to Dr. Karsner's personality, integrity and sympathetic understanding of the problem? How few are the localities where all of these circumstances may be duplicated and if the operation of the plan were not maintained on an exceptionally high plane abuses would creep in. By the same logic the medical college should also send their other young teachers in surgery and in medicine to help out in the small hospital. What has happened elsewhere? The teaching staff has deviated from its primary objective and has engaged in what amounts to a mail order house type of practice of pathology. This system has tended to discourage local hospitals from pooling their local resources thus supporting in their own community a well staffed central laboratory, the personnel of which is available on a moment's notice to render efficient personal service. In my community we have a central laboratory operating branches in each of three smaller hospitals totaling about 250 beds. In addition we provide laboratory service to the local physicians. The cost to patients compares favorably with that in larger institutions and yet the plan affords a profit to the participating hospitals as well as to the organization that serves them. This plan is applicable on a national scale. It can be made to solve the problem more adequately, since it removes the teaching institution from the sphere of extramural practice. Moreover it removes from the hospital the temptation to sell to the public a branch of specialized medicine. It gives to the pathologist an independent sphere of operation through which he may develop a true sense of individual responsibility to the patient and a greatly needed service to his colleagues not only by examining the surgical specimens but also by the performance of postmortems, the daily supervision of all the laboratory tests

and above all the interpretation of these tests in the light of the clinical picture. The American Society of Clinical Pathologists, at its annual meeting in Kansas City, will conduct a symposium on this subject. The great need in the problem of laboratory service for the small hospital lies in the development of centralized local units operating in nearby branches and independently of teaching laboratories. The excess energies of the latter may very well be directed toward training the personnel to man these centralized units. It is something to reflect on that the number of teaching pathologists who are prepared to give advanced instruction in pathology is decidedly limited. To bring this point home, we are faced each year with the problem of finding some one whose breadth of knowledge and experience qualifies him to conduct a seminar in cellular pathology.

DR NORBERT ENZER, Milwaukee. I work as a director in a small hospital. In a laboratory servicing a hospital whose daily average of occupancy is from 100 to 120 patients, we provide a laboratory service covering all types of investigation, with the exception that we do not have available animal facilities. We have a staff of technicians and there is one director. I make this description in order to make significant the statement that the laboratory maintains itself and even does better. The question that came to mind when I heard Dr Karsner's presentation was this: He is concerned about servicing the small hospital at a cost not prohibitive to the small hospital. My answer is that, if pathology is practiced as other branches of medicine are practiced, the hospital need not be concerned in the cost of this thing at all. Fees are derived from patients. Patients are charged for everything that is done in a laboratory sense. I would not hesitate to ask the question, then, of these small hospitals who are receiving what I would consider not adequate laboratory direction. What is the revenue received by the hospital from laboratory fees? and also To whom does it go? Pathology is the practice of medicine, and only those licensed to practice medicine can direct laboratories and do such work. Then no one can participate in the benefits of that practice except those who are practicing it, and for those it shall be deemed their judgment as to how it shall be distributed in terms of cost of maintaining those laboratories. If it is accepted that these laboratories are operated on a fee basis, there is hardly a hospital in which the occupancy will run from 100 to 150 patients that cannot afford to have adequate and even progressive laboratory service, under adequate laboratory direction. Now this question of full time. An unfortunate result of that has been that pathologists have been paid and their services evaluated whether or not they gave full time or part time. Not the service was paid for, but the time. That is not in keeping with high professional standards.

DR W D FORBUS, Duke University, N C. I think that an inadequate definition of what a small hospital is has been given. I have been faced with the problem during the last three years of working out some solution for a group of hospitals ranging from fifteen to, let us say, sixty-five beds. It seems that the scheme which has been put forth as adequate for what I should call a large hospital might experience some difficulty in being applied to what I know, in my environment, to be a small hospital. Perhaps that will be taken into consideration in further discussion of the problem.

DR HOWARD T KARSNER, Cleveland. The hospital laboratory certainly should be centrally located, and I further agree that the basement is no place for it. Dr Forbus recognizes that it is impossible to draw a sharp line between what is a large hospital and what is a small hospital. One may say that a hospital of 150 beds, most of which are general beds, is a large hospital. One may say that a hospital of 150 beds, most of which are maternity beds, is a small hospital. While I recognize the fact that there may be limits to this plan, I simply have proposed it as a general principle of operation, to be adopted wherever possible. Dr Enzer's discussion is of the utmost value as representing a point of view that is different from what is expressed in the paper in this sense. I have referred to hospitals which, by virtue of various limitations, are unable to have as pathologist a man who will furnish the major part of his time and attention to that hospital. There are hospitals in which it is possible to have as pathologist a competent well trained man but in many communities that

is not possible, and the problem then is to service that hospital with a part time man. Dr Enzer refers to the matter of a laboratory supporting itself. I think that in the operation of the first class hospital the objective of the laboratory is to supply service to the hospital. Whether that leads to self support or not is beside the point. That is up to the administrator of the hospital. There is, however, a danger inherent in this sort of thing, and that is the exploitation of the laboratory and the director for the benefit of the general funds of the hospital, a thing which should be decried. Where the centrum happens to be a matter of relatively small importance, it is who the centrum is that is important, and whether that "who" is a man operating a private laboratory or a man who is in a university laboratory is unsequential. Certainly the interests of the patient should never be subordinated to the interests of the hospital as a whole. I think the training in the modern medical school gives the graduate a comprehensive view of the place of the clinical laboratory in matters of diagnosis and treatment. I recognize that the house officers need guidance in the performance of the test. That should be provided by the pathologist in the hospital laboratory. To turn over to young graduates the entire responsibility for the clinical laboratory examinations would provide nothing in the way of his education and training. I think his supervision should be in the hands of the pathologist in charge rather than of the technician. This particular matter should be evaluated in the broadest way, giving to the education of the house officers a place of significance and promise not only as regards laboratory work but as regards all the activities of his training. The plan proposed certainly places responsibility on the pathologist who is in charge of the small hospital, but that responsibility is shared by seniors who have greater experience and longer training. Dr Giordano spoke of the mail order type of business, and we should discourage that. We must recognize, however, that private physicians may at times be aided by a service of this kind, provided it is on a consultation basis, not merely sending in a piece of tissue and a request for diagnosis, whether the place the tissue was taken from, the history of the case, the diagnosis and name of the patient is appended or not. We do nothing of that sort. We must know about the patient. The idea that a student of pathology should be occupied only in teaching and research is subversive to the best interests of pathology and medicine. Pathology in a university is the stepping stone between the so called preclinical and clinical divisions, more closely allied to the clinical divisions than to the preclinical divisions. As a university subject it represents an intensely practical field. Where it is proper teaching, it should require attention to the clinical aspects, wherever possible. The university department that is actively engaged in doing practical work in pathology serves the educational interests of the students to greater advantage than if it occupies the place of a so called preclinical science. Granted it should be engaged in research, there are undoubtedly contributions made to investigations which would not take place if the department were divorced from practical work. I do not mean to say that there are not good departments of pathology in our universities which have little association with hospitals. I think, however, that the heads of those departments recognize that they could do better by the students and the staffs if they had close hospital connections than they are able to do without such connections.

#### Use of the Outpatient Department in Medical Education

DR W McKIM MARRIOTT, St Louis. This article appears in full in this issue, page 1442.

#### DISCUSSION

DR ROBERT W KEETON, Chicago. Some of the organization requirements as they apply to the general medical clinic may be summarized. 1 It is obvious that dispensary patients present complex problems and that the opportunities for solving them are smaller than in hospital patients. Hence the clinic should be manned by the most mature students. This means seniors. 2 The dispensary time should furnish the student his opportunity to begin the practice of medicine. He should learn here an approach to the patient and a method of examining him that he will use later in his office. This means that he must be interested in solving this particular patient's prob-

lems It is not important for him to be running from one examining room to another looking at interesting cases This breadth of knowledge is to be obtained elsewhere in the curriculum 3 Some form of an appointment system for patients must be introduced, so that the student will not be rushed in doing his work and yet will have patients returning to him with regularity 4 Patients must be assigned to the student and he must be their physician until he transfers them to an attending man Until the attending man receives the case he acts solely in a consulting capacity In the order of their importance, the medical school's responsibilities to medical education are 1 To provide facilities by which students may study patients independently and assume responsibility for their medical care 2 To provide an attending staff capable of giving guidance and acting in the capacity of consultants 3 To provide for sufficient extramedical assistance for the establishment of a service as described by Dr Marriott in which preventive medicine will assume a more and more important role and to which the former graduates of the school may return for instruction and stimulation I feel that such a clinic would enable the school to meet satisfactorily the demands for so-called graduate work which up to date have been largely ignored

DR JOHN V LAWRENCE St Louis All of the progress made by outpatient departments during the past few years is integrated in a change of purpose of these departments from dispensaries for the medical relief of symptoms to institutions for complete medical service On the one side these changes are the result of two converging factors (1) the enormous increase in medical knowledge and procedures (2) a changed attitude on the part of the lay public who now demand the benefits of medical knowledge as their rightful privilege Complete or adequate medical service to the patient not only fulfills the responsibility of an outpatient department in its respective community but constitutes the irreducible minimum of teaching procedure and example to medical students The care of the patient today implies a consideration of a cross section of his health picture which includes the patient's picture as a whole pathology, psychology and social and environmental factors of adjustment New consideration of standards and methods for conducting outpatient departments has been under way during the past few years Soon a minimum of standards will be recommended for outpatient departments the country over, classified, let us say and even evaluated standards as to (1) professional excellence of practice in the departments whereby the best medical supervision may be stressed, (2) admission of patients whereby they are controlled and allocated to divisions for the most adequate care, (3) incisive and accurate accounting of costs and statistical analysis of pertinent and guiding data, (4) optimal inclusion of social service in the clinic organization in order to interpret more adequately the patient to the physician and the physician to the patient, thus to formulate the concept of the place of social service for oncoming physicians (5) controlled conduct of the patient's attendance throughout the clinic and discharge from treatment with appropriate follow-up information and guidance (6) unified records of the medical care of the patient whether ambulatory or bedfast These standards as well as others, are necessary for the changing era in medical care and teaching The outpatient department can no longer be considered merely a feeder for hospital wards but takes its place significantly in the march toward preventive medicine as a reality and adequate medical care of the people

DR B R SHURIN Detroit The new problem of changing medical economics has brought with it a wave of control and jurisdiction by the various county societies over the dispensaries and outpatient departments in our large cities It is well and good that some modification and control of a reckless and ruthless increase of patients in the dispensaries that have been not carefully guarded as to who may be their family doctor and where they may likely be sent is a very judicious criticism It seems to me that the county society and the practitioner in general must realize that there are two distinct classes of outpatient departments one that is truly and instinctively the teaching ideal the idea of a student contact which is absolutely essential to the medical school We could greatly improve our outpatient service by paying the men who serve in that service and we have in Detroit established that feature of the

outpatient teaching department whereby men shall receive some remuneration for their services The new wave that has come over our profession is the wave of specialism and the large number of 35 per cent of our men classified either rightly or by themselves as specialists is an alarming fact It has been my privilege to be on the Board of Examiners for Otolaryngology and during nine or ten years we have examined more than 2,000 men The feeling which I have is that our medical education should be most certainly modified and directed more strenuously away from specialism and more highly concentrated on the fundamentals of bedside medicine and the outpatient department, with its fundamentals and basic interrelationships between the physician and the patient It is not unusual for us to examine men who have patients under their observation in the outpatient department as we examine them and who have acute diseases acute discharging ear or acute throat disorder, who will never take their temperature never feel their pulse and never suggest the examination of their chest Should we not come back more strongly in our medical schools to this fundamental basic outpatient department, where our men will be taught psychologically and economically and generally that the great service of the physician is the understanding of his patient and the grand humanitarianism that has gone through these many years with our general practitioners?

(To be continued)

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION PUBLIC HEALTH ETC)

### CALIFORNIA

**Society News**—Dr Kenneth H Sutherland Santa Ana, was chosen president-elect of the Southern California Public Health Association at its recent annual meeting and Raymond V Stone, director, bureau of laboratories Los Angeles County Health Department, Los Angeles was installed as president —The Los Angeles County Medical Society offered a non-medical program at its general meeting March 19 Mr Maurice Zam concert pianist and Mr Alexander Kisselburgh concert stage baritone performed and William A Fowler BE of the California Institute of Technology Pasadena, discussed 'Recent Developments in Physics and Dr Arthur Elmer Belt 'Book Hunting—A Sport for the Doctor's Leisure'

**Annual Tuberculosis Meeting**—The California Tuberculosis Association held its annual meeting in Sacramento April 2-4 Guest speakers included Dr J W Arthur Myers Minneapolis on The Contribution of Organization and Mr Homer N Calver, New York Respiratory Diseases, in Unmet Challenge Dr Myers also addressed the annual banquet Other speakers included Drs Louis H Giles and Elphège A Beaudet, Livermore 'Some Factors Influencing the Reactivation of Patients Discharged from Our Sanatoria', Ross W Harbaugh San Francisco, 'Tuberculosis as an Industrial Problem' Emil Bogen Olive View Thermotherapy in Tuberculosis John C Jones, Los Angeles Lobectomy for Uncontrolled Pulmonary Hemorrhages in Tuberculosis and Sidney I Shipman San Francisco, Tuberculous Stenosis of the Bronchus

### COLORADO

**Society News**—Dr Johnson E Naugle Sterling, among others addressed the Northeast Colorado Medical Society in Sterling March 12 on pleurodynia —Dr Harry Gruss, among others addressed the Medical Society of the City and County of Denver, April 7 on Gastro Intestinal Symptoms of Pelvic Origin

**Spring Graduate Clinics**—The annual spring graduate clinics presented by the Pueblo County Medical Society under authorization of the committee on postgraduate clinics of the Colorado State Medical Society will be held in Pueblo April 29-May 1 Sessions will be held at St Mary's Colorado State and Parkview hospitals Guest speakers will include Dr William W Watson, Dr Walter W King Paul Maltby Clark and Paul P Prosser attorneys all of Denver The subjects of Dr Watson and Dr King will be Medical Economics and The Doctor in Politics respectively

## DELAWARE

**Society News**—Dr John M T Finney Sr, Baltimore, discussed "The Role of the Imponderables in Surgery" before the New Castle County Medical Society in Wilmington, April 21. Dr William Wayne Babcock, Philadelphia, addressed the society March 17 on "Diagnosis and Treatment of Intestinal Malignancy and Hirschsprungs Disease."

## DISTRICT OF COLUMBIA

**Medical Bills in Congress**—H R 11548, introduced by Representative Mitchell, Illinois proposes to direct the Commission on Licensure to Practice the Healing Art in the District of Columbia to issue a license to practice the healing art to Dr Clarence Q Pair. H R 12242 has been reported to the House with recommendation that it pass, proposing to revise the lunacy proceedings in the District of Columbia.

## FLORIDA

**Banquet to Medical Officers**—The Dade County Medical Society gave a banquet in Miami, February 26, in honor of Drs James S McLeister, Birmingham Ala. President, American Medical Association, Herbert L Bryans, Pensacola, president of the Florida Medical Association, and Julius C Davis, Quincy, past president of the state association.

**Society News**—Dr John J Kindred DeLand addressed the Volusia County Medical Society in New Smyrna, March 10, on 'Modern Conception of Epilepsy and Its Treatment'. —Dr Herbert L Bryans Pensacola discussed medical economics before the Bay County Medical Association in Panama City, March 5. Other speakers included Drs Julius C Davis Quincy on medical legislation, and Walter C Payne, Pensacola, infections of the cervix uteri.

## GEORGIA

**Statue of Dr Crawford Long Unveiled**—A statue erected in Danielsville by the state of Georgia in honor of Dr Crawford W Long, the first physician to use ether anesthesia, was unveiled March 30. The legislature authorized the erection of the memorial at or near Dr Long's birthplace. Mrs O A Harper daughter of Dr Long and E C Long Jr assisted in the unveiling. Speakers included Governor Eugene Talmadge, Dr Lamartine G Hardman Commerce, former governor, Dr James E Paulin Atlanta president of the state medical association, and Dr Hugh H Young Baltimore.

**Society News**—Dr Cleveland Thompson Millen, discussed "The Autonomic Nervous System among other speakers before the Burke-Jenkins-Screven Counties Medical Society at a meeting in Millen recently. —The Baldwin County Medical Society was addressed at Milledgeville among others, recently by Dr Lovick P Longino on 'Vertigo and Its Relation to Infections of the Mastoid Antrum'. —Speakers before the Chatham-Savannah Tuberculosis Association recently were Drs John L Elliott on pneumothorax and Ruskin King Savannah new tuberculin purified protein derivative. —The Georgia Medical Society, Savannah was addressed recently by Drs Job C Patterson, Cuthbert, on Acid Ulcer with Especial Reference to Acute Perforation' and Charles K McLaughlin, Savannah, 'Convergent Strabismus'. —At a meeting of the Colquitt County Medical Society in Moultrie, recently Drs James R Paulk and John B Woodall both of Moultrie, discussed allergy and bronchial asthma respectively.

## ILLINOIS

**Tumor Clinic**—Dr Charles F Geschickter of Johns Hopkins Hospital Baltimore conducted a tumor clinic at Silver Cross Hospital Joliet March 25. This was the third annual clinic of its kind. The first was conducted by the late Dr Joseph C Bloodgood, Baltimore, and the second by Dr Geschickter.

**Society News**—The Adams County Medical Society was addressed in Quincy April 13, by Drs Bernard Portis and Max Cutler Chicago on Acute Surgical Abdominal Conditions and Recent Advances in the Treatment of Cancer respectively. —At a meeting of the St Clair County Medical Society in Belleville, April 1 Dr Edward W Cannady Jr East St Louis discussed Diagnosis and Treatment of Cardiac Arrhythmia. At the session in East St Louis April 2 Dr James S Templeton Pinckneville addressed the society on Responsibility of the Individual Doctor to His Profession.

## Chicago

**Society News**—Dr Byrl R Kirklm, Rochester, Minn., among others, presented "A Roentgen Study of the Stomach and Duodenum After Operation" before the Chicago Roentgen Society, April 9. —At a meeting of the Chicago Pathological Society, April 13, speakers included Drs Paul E Steiner on "Malignant Lymphogranulomatous (Hodgkin's Disease) Cirrhosis of the Liver" and Sol R Rosenthal, "Tissue Lymphocytes in the Prognosis of Hodgkin's Disease."

**Admiral Blackwood Leaves Provident Hospital**—Rear Admiral Norman J Blackwood has announced his retirement as medical director of Provident Hospital, after more than five years service there. He graduated at Jefferson Medical College, Philadelphia, in 1888 and entered the navy in 1889, advancing through the grades until 1929, when he was retired as a rear admiral. Provident Hospital, a training center for Negro medical workers, is housed in the remodeled home of the old Chicago Lying-In Hospital. The development and maintenance of the center was made possible by a \$3,000,000 fund subscribed in 1930, \$1,000,000 of which was a gift from the General Education Board of the Rockefeller Foundation. Dr John W Lawlah, director of the institution's x-ray department, has been appointed to succeed Dr Blackwood. He is 32 years of age and graduated from Rush Medical College in 1932.

## INDIANA

**Dr Mettel Named Director of Child Health**—Dr Howard B Mettel, secretary of the Indianapolis Medical Society, has been appointed director of the department of child and maternal health of the state division of public health. This appointment is made under the provisions of the federal social security act it is reported. Dr Mettel graduated from the University of Michigan School of Medicine, Ann Arbor, in 1921.

**Health at Evansville**—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million for the week ended April 11, indicate that the highest mortality rate (31.1) appears for Evansville and for the group of cities as a whole, 12.9. The mortality rate for Evansville for the corresponding period last year was 11.6 and for the group of cities, 11.8. The annual rate for eighty-six cities for the fifteen weeks of 1936 was 13.7 as against a rate of 12.7 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

**Society News**—At a meeting of the Tippecanoe County Medical Society in Lafayette, March 10, Dr Delbert O Kearby Indianapolis, discussed diagnosis and treatment of chest diseases with the use of the bronchoscope and x-rays. —The Elkhart County Medical Association, Elkhart, was addressed March 5 by Dr Charles W Mayo, Rochester, Minn., on "Pain in Cholecystitis and Recurring Attacks of Pain Following Cholecystectomy". —Dr Larue D Carter, Indianapolis, discussed 'Diagnosis of the Common Neurologic Diseases' before the Fayette-Franklin County Medical Society in Connersville March 10. —The Kosciusko County Medical Society was addressed in Warsaw March 10, by Drs George N Herring Piercetown, and George W Anglin, Warsaw, on mucous and tuberculous colitis, respectively. —At a meeting of the Muncie Academy of Medicine in Muncie, March 10 Drs Ezra Vernon Hahn and Edwin Rogers Smith, Indianapolis discussed Head Injuries and Their Medicolegal Aspects.

## IOWA

**Society News**—The Iowa Hospital Association will hold its annual convention at the Hotel Fort Des Moines, April 27-28. —A symposium on cardiovascular diseases was presented before the Des Moines Academy of Medicine and the Polk County Medical Society March 31 by Drs Lee Forrest Hill, Walter D Abbott, Des Moines, and Allan G Felter, Van Meter.

**Public Health Meeting**—The tenth annual meeting of the Iowa Public Health Association will be held in Des Moines at the Hotel Savoy, April 28. A symposium on the social security act has been arranged for the noon luncheon session with the following physicians participating: Albert J Cheslev, St Paul, Walter L Bierring, Des Moines, Joseph H Kinna.

man, Des Moines, Arthur Steindler, Iowa City, and Mae H. Habenicht, Des Moines. In addition the following physicians will present papers:

Raymond A. Vonderlehr, Washington, D. C., Syphilis as a Public Health Problem.  
Carl F. Jordan, Des Moines, Progress in Communicable Disease Control.  
Archibald L. Hoyne, Chicago, When Diphtheria Threatens to Take a Life.  
Sidney O. Levinson, Chicago, Value of Human Convalescent Serum in Measles and Poliomyelitis.

## KANSAS

**Class in Public Speaking**—The committee on public education of the Sedgwick County Medical Society recently instituted a series of meetings to give members experience and training in public speaking. Assignments are made at each session and five minute talks are presented by several members at the following meeting. Other members offer criticism, and the chairman elected at each session is criticized on his conduct of the meeting. Thirty members of the society are enrolled.

**Society News**—Dr. William J. Feehan, Kansas City, discussed "Fractures of the Neck of the Femur" before the Wyandotte County Medical Society, March 17. Clarence C. Little, D.Sc., managing director, American Society for the Control of Cancer, New York, also spoke. Dr. John R. Nilsson, Omaha, among others, addressed the Golden Belt Medical Society in Junction City, April 2, on "Surgical Conditions of the Esophagus." The Marion County Medical Society was addressed recently in Marion by Drs. John B. Nanninga, Goessel, on "Death of an Infant from the Inhalation of Fumes from a Patent Asthma Cure" and Ralph R. Melton, Marion, Kidney Tumors of Infancy. Dr. Roland M. Klemme, St. Louis, discussed diagnosis and treatment of trigeminal neuralgia before the Sedgwick County Medical Society, Wichita, April 21.

## LOUISIANA

**State Medical Meeting at Lake Charles**—The fifty-seventh annual meeting of the Louisiana State Medical Society will be held at Lake Charles, April 27-29, with headquarters at the Charleston Hotel and under the presidency of Dr. Courtland P. Gray, Sr., Monroe. Mr. St. Clair Adams, New Orleans, will give the annual oration Tuesday evening and guest speakers will include:

Dr. Arthur T. McCormack, Louisville, The Health Unit and Its Problems.  
Dr. Frank H. Hagaman, Jackson, Miss., Jaundice.  
Dr. George B. Eusterman, Rochester, Minn., Gastric Carcinoma Masquerading as a Benign Lesion With Particular Reference to the Small Circumscribed Ulcerous Type.  
Dr. John L. McGhee, Memphis, Tenn., Treatment of Acute Intestinal Obstruction.

Monday the dinner for past presidents of the society and memorial services for deceased members will be held and Tuesday evening Dr. Gray will receive the medal given each year to the retiring president. Other speakers on the scientific program will include:

Ernest Carroll Faust, Ph.D., New Orleans, Public Health Aspects of Parasitic Infections in the Southern United States with Special Reference to Louisiana.  
Dr. J. Rigney D'Aunoy, New Orleans, Poliomyelitis.  
Dr. Edwin A. Socola, New Orleans, Physical Defects in Children of Preschool and School Age.  
Dr. William H. Seemann, New Orleans, Endemic Typhus.  
Dr. Morgan Smith, Jennings, La., Lobar Pneumonia.  
Dr. Morris Shushan and Mr. Oscar Blitz, New Orleans, Factors Influencing Morbidity and Mortality in Benign Tertian and Estivo Autumnal Malaria.  
Dr. Melville W. Hunter, Monroe, Observations in Acute Coronary Occlusion.  
Dr. Marion D. Hargrove, Shreveport, Auricular Fibrillation.  
Dr. Rena Crawford, New Orleans, Congenital Heart Disease with Reports of Cases and Presentation of Pathological Specimen.  
Dr. Clifford R. Mays, Shreveport, Maternal Welfare in Louisiana.  
Dr. Daniel M. Moore, Monroe, Mycotic Infection of the Lungs.  
Dr. Charles B. Odom, New Orleans, Use of Epidural Anesthesia in General Surgery.  
Dr. David R. Womack, New Orleans, Treatment of Allergy with Nasal Ionization.  
Dr. Emile A. Bertucci, New Orleans, Introduction of a New Vegetable Concentrate in the Treatment of Diabetes Mellitus.  
Dr. Leon J. Menville, New Orleans, Preoperative Irradiation of Cancer of the Breast.

## MICHIGAN

**Scientific Exhibits Committee**—At a recent meeting of the Council of the Michigan State Medical Society, a scientific exhibits committee was created to take charge at the annual meeting at the Book-Cadillac Hotel, Detroit, September 21-24. Dr. Clifford T. Ekelund, Pontiac, is chairman and other members are Drs. Samuel W. Donaldson, Ann Arbor; William M. German, Grand Rapids; and Arthur E. Schiller and Eldwin R. Witwer, Detroit. A new feature of the exhibit will be a hobby show.

**Society News**—Dr. Loren W. Shaffer, Detroit, discussed "Dermatoses of Diagnostic Significance in General Medicine" before the Highland Park Physicians' Club, March 12. At a meeting of the Genesee County Medical Society, March 4, Dr. William J. Cassidy, Detroit, discussed "Selective and Anastomotic Surgery in Life Comfort and Extension." He addressed the Huron-Sanilac County Medical Society, March 6, on "Ectopic Pregnancy." The Grosse Pointe Medical Club, Detroit, was addressed March 11 on "Modern Trend of Tuberculosis" by Dr. Bruce Douglas. At a meeting of the Michigan Society for the Promotion of Dentistry for Children, March 11, the following Detroit physicians spoke: Roger S. Siddall, obstetrics; Allan L. Richardson, pediatrics; John A. Hooke, dermatology; Frederick J. Fischer, orthopedics; Arthur P. Wilkinson, ear, eye, nose and throat; and Benjamin I. Johnstone, the heart.

**Department of Physical Therapy Dedicated**—The dedication of a new therapeutic pool and new quarters of the department of physical therapy of University Hospital, Ann Arbor, took place February 27. Preceding a tour of inspection, a luncheon was given for the heads of the various departments, executives of the university and the trustees of the Horace H. and Mary A. Rackham Fund, which financed the new pool. The department of physical therapy now occupies an entire wing of the basement floor of the hospital. The pool, which is only a portion of the unit, is 25 feet long and 15 feet wide and varies in depth from 2½ feet to 4½ feet. It is supplied by a constant recirculating system, which filters and chlorinates the water and maintains it at a temperature of 90 F. Paralyzed patients may be conveyed into and from the pool by means of a trolley arrangement. There are also two large tanks for individual treatments.

**Tribute to Dr. Biddle**—The Wayne County Medical Society and the Detroit Dermatological Society sponsored a reception and dinner in honor of Dr. Andrew P. Biddle, April 1, to commemorate his completion of fifty years in the practice of medicine. Dr. Biddle graduated from Detroit College of Medicine where he has been emeritus professor of dermatology since 1917. He was a member of the state board of health for six years, president of the Detroit Board of Education in 1925, president of the Detroit Library Commission in 1931 and a member since 1926. He is a charter member of the Wayne County Medical Society and in 1902 became the first editor of the *Journal of the Michigan State Medical Society*. He was president of the state society during the World War. He has also been president of the American Dermatological Society and of the Detroit Academy of Medicine. Speakers at the dinner included Judge Ernest A. O'Brien, former governor; Fred W. Green, Rabbi Leo M. Franklin and Drs. Douglas Donald, Don M. Campbell, Loren W. Shaffer and Robert C. Jameson.

## MINNESOTA

**University News**—A grant of \$13,250 from the U. S. Public Health Service has made possible the establishment of special courses in public health work at the University of Minnesota, beginning with the spring quarter.

**State Medical Meeting in Rochester**—The eighty-third annual session of the Minnesota State Medical Association will be held in Rochester, May 3-6, with headquarters at the Kahler Hotel and under the presidency of Dr. William W. Will, Bertha. Guest speakers will include the following physicians:

Leon A. Berne, Switzerland, Functions of the Spleen.  
Elliott P. Jo lin, Boston, Treatment of Diabetes.  
Ferdinand Sauerbruch, Berlin, Germany.  
Frederick A. Collier, Ann Arbor, Studies in Water Balance Dehydration and the Administration of Parenteral Fluids.  
Donald Guthrie, Sayre, Pa., Surgical Aspects of Peptic Ulcer.

Dr. Willis F. Manges, Philadelphia, will present the Russell D. Carman Memorial Lecture sponsored by the Minnesota Radiological Society. His paper will be entitled "Foreign Bodies and the Use of X-Ray Examination in their Localization and Removal." Other physicians on the program will include:

Edward I. Tuohy, Duluth, Treatment of Gall Tract Disease as Determined by the Stage of Its Development and the Patient's General Condition.  
Oscar E. Locken, Crookston, Oxygen Therapy.  
Henry E. Michel, Minneapolis, A Few Axioms in Dermatologic Diagnosis.  
Martin O. Wallace, Duluth, Management of the Minor Ailments of Pregnancy.  
Hiram J. Lloyd, Mankato, Congenital Heart Defects—Importance of Early Diagnosis.  
Edward A. Regnier, Minneapolis, Management of Appendicitis.  
George A. Earl, St. Paul, Role of Duodenoduodenostomy for Duodenal Ulcers and Duodenal Obstruction.  
Olaf J. Hagen, Moorhead, Regional or Terminal Ileitis.  
James J. Swend, St. Paul, Induction of Obstetrical Amnesia and Analgesia.

Edward N. Peterson, Eveleth, Blood Transfusion  
 Orwood J. Campbell, Minneapolis, Bumper Fractures of the Tibia  
 Warner G. Workman, Tracy, Erythema Multiforme Complicated by  
 Severe Gastrointestinal Disturbances and Hemorrhage from Mucous  
 Membranes in a Priapism  
 Frederic E. B. Foley, St. Paul, Surgical Treatment of Hydronephrosis,  
 a New Operation for the Relief of Ureteropelvic Junction Stricture  
 Mark H. Tibbitts, Duluth, Changes in Aortic Shadows Following  
 Injuries to the Spine  
 Morse J. Shapiro, Minneapolis, Diagnostic and Therapeutic Problems in  
 Heart Disease in Children  
 Gordon R. Kamman, St. Paul, Correlations Between Variations in  
 Barometric Pressure and Incidence of Cerebral Hemorrhage  
 Leo G. Rigler, Minneapolis, The Roentgen Findings in Biliary Fistula  
 George N. Rubberg, St. Paul, Myxedema: Its Nervous and Mental  
 Manifestations  
 Charles H. Mead, Duluth, Ovarian Hemorrhage Simulating Acute  
 Appendicitis  
 Everett K. Geer, St. Paul, Active Pulmonary Tuberculosis Without  
 Symptoms  
 Reuben A. Johnson, Minneapolis, Gonorrheal Pelvic Inflammatory  
 Disease

Monday afternoon there will be a symposium on causes  
 diagnosis and treatment of hay fever by Drs. Ralph V. Ellis  
 and Horatio B. Sweetser Jr., Minneapolis and C. O. Rosen-  
 dahl, Ph.D. An evening meeting Monday will be addressed by  
 Drs. Charles W. and William J. Mayo, Rochester. Mrs. Ernest  
 M. Hammes, St. Paul, president-elect, woman's auxiliary. Dr.  
 Olin West, Secretary and General Manager American Medical  
 Association, and Dr. Will. Among the exhibits will be one  
 on crime detection methods, prepared by the federal bureau of  
 investigation.

### MISSISSIPPI

**Personal**—Dr. Charles D. Mitchell, Gulfport has been  
 appointed superintendent of the Mississippi State Hospital.  
 Whitfield—Dr. John W. Dugger, Jackson has been named  
 director of the Pearl River County Health Unit succeeding  
 Dr. George E. Godman, Poplarville who resigned—  
 Dr. Roger Mayo Flynn has been appointed superintendent of  
 the Newton Infirmary, Newton.

**Society News**—At a meeting of the Northeast Mississippi  
 Thirteen County Medical Society in Starkville, March 17,  
 speakers included Drs. Robert D. Kirk Jr., Tupelo on 'Abuse  
 of Uterine Curette,' and Henry G. Rudner, Memphis, Tenn.  
 'Agranulocytosis'—Dr. Norman E. Applewhite, Jackson  
 read a paper on 'Some Phases of Peroral Endoscopy' before  
 the Central Medical Society in Jackson, February 4.

### NEBRASKA

**Alumni Dinner at Kansas City**—The alumni of the Uni-  
 versity of Nebraska College of Medicine will meet at a dinner  
 during the annual session of the American Medical Association  
 in Kansas City, Mo. Wednesday evening, May 13 at the Hotel  
 Kansas City. Dr. Benjamin L. Myers, 1115 Grand Avenue  
 Kansas City is chairman.

**Society News**—Drs. Esley J. Kirk and Howard B.  
 Hamilton, Omaha, addressed the Scottsbluff County Medical  
 Society, March 12, on 'Diseases of the Kidney' and 'The  
 Respiratory Tract from the Standpoint of Pediatrics' respec-  
 tively. At an evening meeting the speakers presented papers  
 on 'Lung Conditions in Children' and 'Problems of Water  
 Balance' respectively—Drs. John F. Gardiner and James F.  
 Kelly, Omaha, addressed the Omaha-Douglas County Medical  
 Society, April 28, on 'Difficulties in the Recognition of Hypo-  
 thyroidism' and 'Use of the X-Rays as an Aid in the Treat-  
 ment of Infectious Processes' respectively.

### NEW HAMPSHIRE

**Society News**—Drs. Clifton S. Abbott, Laconia, and Car-  
 leton R. Metcalf, Concord president and secretary respectively  
 of the New Hampshire Medical Society, addressed the Bel-  
 knap County Medical Society, Laconia, recently—Dr. Dudley  
 Merrill, Boston recently addressed the Hillsborough County  
 Medical Society on 'Dangers Inherent in the Clinical Diagnosis  
 of Cancer'—A commission for the study of occupational  
 diseases was recently appointed with Dr. Robert J. Graves,  
 Concord as chairman. Among members are Drs. Emory M.  
 Fitch, Claremont and David W. Parker, Manchester.

### NEW JERSEY

**Graduate Lectures**—The Camden County Medical Society  
 is sponsoring a series of graduate lectures during April and  
 May. The series is as follows:

Dr. William Goldring, New York, April 8, Nephritis and April 15,  
 Hypertension, Hypertensive and Arteriosclerotic Heart Disease  
 Dr. Eldridge L. Eliason, Philadelphia, April 22, Diagnosis of Surgical  
 Abdominal Conditions  
 Dr. Jacob Irving, Fort Newark, April 29, fracture clinic  
 Dr. Charles Hendee Smith, New York, May 6, pediatric clinic  
 Dr. Robert A. Matthews, Philadelphia, May 13, The Commoner  
 Psychoses

### NEW MEXICO

**State Medical Meeting at Carlsbad**—The annual meet-  
 ing of the New Mexico Medical Society will be held at Carls-  
 bad, May 6-8, with headquarters at the Crawford Hotel.  
 Among speakers will be:

Dr. Donald H. O'Rourke, Denver, A Consideration of Eye Problems  
 of the General Practitioner  
 Dr. Leslie M. Smith, El Paso, Texas, Atopic Dermatitis and Contact  
 Dermatitis  
 Dr. Charles L. Martin, Dallas, Texas, Advanced Cancer About the  
 Head and Neck  
 Dr. Benjamin L. Schofield, Dallas, Indications for Open Operation  
 in Fractures  
 Dr. E. Payne Palmer, Phoenix, Ariz., Emergency Treatment of  
 Fractures  
 Dr. Alexander E. Brown, Rochester, Minn., Clinical Aspects of  
 Jaundice  
 Dr. John L. Murphy, El Paso, Varicose Veins  
 Dr. James Shirley Sweeney, Dallas, Modern Concept of Diabetes  
 Mellitus  
 Dr. George Turner, El Paso, Blood Transfusion  
 Dr. Clarence B. Ingraham Jr., Denver, Sterility  
 Dr. Adolf W. Muthauef, El Paso, Practical Points in Diagnosis and  
 Treatment of Cystitis  
 Dr. Fred W. Standefer, Lubbock, Texas, Allergy—Its Relation to  
 Diseases of the Eye

In the public health section, which meets Thursday, May 7,  
 speakers will include Drs. William W. Bauer, Chicago, director,  
 Bureau of Health and Public Instruction, American Medi-  
 cal Association, Reginald M. Atwater, executive secretary,  
 American Public Health Association, New York, and Karl F.  
 Meyer, Ph.D., San Francisco. Friday's sessions, a luncheon  
 round table session and a general meeting, will be held at the  
 Carlsbad Cavern. Dr. Mallory B. Culpepper, Carlsbad, will  
 be installed as president at the opening session Wednesday, to  
 succeed Dr. Charles W. Gerber, Las Cruces.

### NEW YORK

**Society News**—A symposium on cancer of the larynx was  
 presented at the annual meeting of the Eastern New York Eye,  
 Ear, Nose and Throat Association in Schenectady, April 15,  
 by Drs. Chevalier Jackson, Chevalier L. Jackson and William  
 Edward Chamberlain, all of Philadelphia—Dr. Hugh Cabot,  
 Rochester, Minn., addressed the Medical Society of the County  
 of Westchester, Valhalla, April 21, on 'Management of the  
 Cryptorchid'—Dr. Frederick A. Collier, Ann Arbor, Mich.,  
 addressed the society, March 17, on 'Water Balance and Dehy-  
 dration in the Sick Patient'—The Medical Society of the  
 County of Rensselaer began the publication of a bulletin with  
 the April issue. The society was addressed April 14 by  
 Mr. Dwight Marvin on 'The Physician as a Layman and an  
 Editor Sees Him', Drs. Alton J. Hull, 'Cooperative Medical  
 Practice' and Augustus J. Hambrook, Troy, 'Hard of Hearing  
 Problems in Our School Children and Methods for Correction'.

### New York City

**Personal**—Dr. Morris Hinenburg, assistant director of  
 Montefiore Hospital for Chronic Diseases, New York, has been  
 appointed director of the Jewish Hospital of Brooklyn—  
 Dr. Milton Benjamin Rosenbluth has been appointed visiting  
 physician to Bellevue Hospital—Dr. Herman J. Burman has  
 been appointed assistant professor of clinical otolaryngology at  
 the New York Post-Graduate Medical School—Dr. James  
 Alexander Miller has been appointed administrative consultant  
 in tuberculosis to the city department of hospitals.

**Annual Physicians Art Show**—The ninth annual exhibi-  
 tion of the New York Physicians Art Club was on view April  
 6-18 at the New York Academy of Medicine with 223 items  
 varying from oil paintings to cabinet work. Landscapes and  
 still life paintings were most numerous among the exhibits.  
 Two memorial groups were shown, one a group of water colors  
 by the late Dr. Albert Henry Fridenberg, the other an unfini-  
 shed sculpture left by the late Dr. Walter Beran Wolfe. The  
 exhibition also included photographs and craft work.

### NORTH DAKOTA

**Diploma Lost**—Dr. William John Pangman, Walperton,  
 recently reported the loss of his medical diploma from the  
 College of Medical Evangelists, Los Angeles, dated June 21,  
 1931.

**Personal**—Dr. James P. Widmeyer, who has been in active  
 practice at Rolla for more than forty years, has been made an  
 honorary life member of the Devils Lake District Medical  
 Society—Dr. Leslie G. Eastman, Hazen, was elected presi-  
 dent of the North Dakota Sixth District Medical Society  
 recently. Dr. George M. Constans, Bismarck, vice president,  
 and Dr. Leonard W. Larson, Bismarck, secretary—Dr. J. W.  
 Moreland, Carpio, has been appointed health officer of Ward  
 County, succeeding Dr. Henry L. Halverson, Minot, who  
 resigned.

## OREGON

**New Officers of State Board**—At a meeting of the state board of medical examiners, April 1, Dr Charles C Newcastle was elected president, Dr Joseph F Wood secretary and Dr Linford S Besson, treasurer. All are of Portland. Other members of the board are Drs Elza D Johnson Klamath Falls and Carl G Patterson, Baker and J L Ingle, D O La Grande. The board adopted regulations to govern licensure of graduates of foreign medical schools. Such applicants must be citizens of the United States and must present satisfactory premedical requirements as outlined by the Council on Medical Education and Hospitals of the American Medical Association and the Association of American Medical Colleges. They must present diplomas indicating graduation from foreign schools that are in good standing in the opinion of the board and they must possess licenses to practice in the country in which they were graduated. Finally, each applicant must satisfy the board that after receiving the foreign diploma and license he has served an internship in a hospital approved by the board.

## PENNSYLVANIA

**Society News**—Dr Hugh H Young, Baltimore, addressed the Cambria County Medical Society, Johnstown, April 9, on "Urologic Problems of General Interest." Dr Paul P Riggie, Washington, addressed the Washington County Medical Society, April 8, on "Peptic Ulcer and Gastric Carcinoma."

### Philadelphia

**Woman Physician Honored**—Dr Marie K Formad was guest of honor at a banquet at the Bellevue-Stratford, March 16, celebrating fifty years of service at the Woman's Hospital. Dr Mary R H Lewis, director of the hospital, presided and Dr Alberta Peltz, president of the staff, presented contributions amounting to \$1,000 to the hospital to be known as the Marie K Formad Endowment Fund. Dr Formad graduated from the Woman's Medical College of Pennsylvania in 1886.

**The Johnson Lectures in Medical Physics**—Drs Joseph Erlanger, professor of physiology, Washington University School of Medicine, St Louis, and Herbert S Gasser, director, Rockefeller Institute for Medical Research, New York, gave the lectures at the Elbridge Reeves Johnson Foundation for Medical Physics at the University of Pennsylvania, March 31-April 7. The subject was "Electrical Signs of Nerve Activity." Both lecturers spoke at the introductory session, March 31, and succeeding lectures were:

- April 1. Analysis of the Compound Action Potential of Nerve. Dr Erlanger.
- April 2. Comparative Physiologic Characteristics of Nerve Fibers. Dr Erlanger.
- April 3. Some Reactions of Nerve Fibers to Electrical Stimulation. Dr Erlanger.
- April 6. Sequence of the Potential Changes. Dr Gasser.
- April 7. The Irritability Cycle. Dr Gasser.

At the opening session the honorary degree of doctor of science was conferred on Dr Gasser and Dr Erlanger by the university.

### Pittsburgh

**Flood Waters in Doctors' Offices**—Flood waters in the printing plant that publishes the *Pittsburgh Medical Bulletin* and in the building containing the offices of the Allegheny County Medical Society made it impossible to print the issues of the bulletin for March 21 and 28. The issue of April 4 quotes the following editorial tribute to Pittsburgh physicians published in the *Pittsburgh Post-Gazette*, March 24:

It was characteristic of their profession that 600 Pittsburgh physicians should immediately have volunteered their services in guarding the public health in the wake of the flood.

In such crises the doctors are always in the first line of defense working unselfishly, heroically. And how quietly and effectively they work.

There could be no higher tribute to the profession than the fact that it was expected to do this as a matter of course—and it never disappoints.

Pittsburgh newspapers issued from the presses of papers in neighboring towns carried messages of advice to the flood-stricken area from city, county and state health authorities and the county medical society the bulletin said. Radio station KDKA also cooperated under the greatest difficulties in broadcasting such advice as could be given by the health authorities. The *Pittsburgh Medical Bulletin* quoted a communication from the Medical Society of the State of Pennsylvania as follows:

We cannot close this communication without bringing to your sympathetic attention the plight of probably 200 of our state society members scattered across the state (fifty of them in Johnstown) through whose first floor combined offices and residences flowed from 5 to 12 feet of destructive flood waters.

## SOUTH DAKOTA

**State Medical Meeting at Sioux Falls**—The fifty-fifth annual session of the South Dakota Medical Association will be held in Sioux Falls, May 4-6, with headquarters at the Cataract Hotel. Guest speakers will be:

- Dr Robert D Schroek, Omaha: Fractures of the Elbow and Fractures of the Knee Joint.
- Dr Jay Arthur Myers, Minneapolis: Modern Methods of Controlling Tuberculosis.
- Dr Roscoe G Leland, Chicago: Director, Bureau of Medical Economics, American Medical Association: Changes Confronting Modern Medicine.
- Dr Robert Glenn Allison, Minneapolis: subject not announced.
- Dr Joseph C Ohlmacher, dean, University of South Dakota School of Medicine, Vermillion: Organic Basis for Hypo Insulinism and Hyperinsulinism.
- Dr Elliott P Joslin, Boston: clinic on diabetes.

The South Dakota Academy of Ophthalmology and Otolaryngology will meet May 6, with the following speakers: Drs Otis R Wolfe, Marshalltown, Iowa, "Cataract Extraction by the Barraquer Method" and William H Griffith, Huron, "Schilling Hemogram in Acute Infections." Dr Albert S Rider, Flandreau, is president of the state medical association and Dr James L Stewart, Nemo, president-elect.

## UTAH

**New Health Commissioner**—Dr Thomas J Howells has recently been appointed health commissioner of Salt Lake City to succeed Dr Sol G Kahn. Dr Howells was graduated from Jefferson Medical College, Philadelphia, in 1910.

## GENERAL

**Milk Commissions to Meet**—The annual joint meeting of the American Association of Medical Milk Commissions and the Certified Milk Producers Association of America will be held in Kansas City, May 11-12, at the Hotel Baltimore, under the presidency of Dr Milton J Rosenau, Chapel Hill, N C. Among speakers will be:

- Boyd S Gardner, DDS, Rochester, Minn.: Nutrition as Affecting the Teeth.
- Dr Paul J Zentay, St Louis: Problems Ahead for Certified Milk.
- Dr Harold L Barnes, Brooklyn: Shall We Continue to Certify Milk?
- Dr Oscar Reiss, Los Angeles: A Suitable Milk for Infant Feeding.
- Dr Edwin T Wyman, Boston: Milk in Infant Feeding.
- Dr Hugh I Dwyer, Kansas City: Importance of Certified Milk in the Diet After Infancy.
- Conrad A Elvehjem, Ph D, University of Wisconsin, Madison: The Growth Promoting Factor in Milk.

**Association for Research in Ophthalmology**—The annual meeting of the Association for Research in Ophthalmology will be held May 12 in Kansas City at Edison Hall, Power and Light Building. The program is as follows:

- Dr Otto Barkan, San Francisco: Goniotomy or Incision of Schlemm's Canal for Chronic Glaucoma—Results of Gonioscopic Research.
- Dr Earl L Burkly, Baltimore: Studies on the Action of Staphylococcus Toxin and Antitoxin with Special Reference to Ophthalmology.
- Drs Richard T Thompson, Edward Gallardo and Deborah Leachte, New York: Precipitins in the Ocular Tissues of Rabbits Generally and Locally Immunized with Crystalline Egg Albumen—Their Relationship to Allergy.
- Dr George E Park, Chicago: An Investigation of the Angular Relation of the Visual and Optic Axes.
- Dr Karl Meyer and John W Palmer, Ph D, New York: The Nature of Ocular Fluids.
- Dr William M James and A J Siefer, Ph D, St Louis: Observations on the Reducing Substances (Glucose) of the Aqueous and Vitreous Humors of the Eye.
- Drs Placidus J Leinfelder and Harold D Kerr, Iowa City: Roentgen Ray Contrast—An Experimental Histologic and Clinical Study.
- Dr Conrad Beren, Edith I Nilon and George H Chapman, New York: Iritis Produced in Rabbits Eyes by Intravenous Injection of Crude and Purified Cultures of Bacteria Isolated from Patients with Certain Inflammatory Eye Diseases.

**Medical Bills in Congress**—Change in Status. H R 3629 has been vetoed by the President, proposing to authorize the acquisition of additional land for Walter Reed General Hospital. **Bills Introduced**. S 4429, introduced by Senator Thomas, Utah, proposes to create an executive department of the government to be known as the Department of Education and Public Welfare. S 4489, introduced by Senator Hatch, New Mexico, proposes to provide compensation and medical care for enrollees in the Civilian Conservation Corps suffering disability or death resulting from injury sustained in the performance of duty. H R 12300, introduced by Representative Smith, Washington, proposes to provide a uniform rate of pension for unmarried Spanish-American War veterans without dependents while hospitalized and to extend hospitalization to persons recognized as veterans of the Spanish-American War under laws in effect prior to March 20, 1933. H R 12245, introduced by Representative Scruggs, Nevada, proposes to authorize the President to provide for employing unemployed citizens of the United States to discover and develop the mineral resources of the public lands of the United States, and to provide medical care and hospitalization for such employees.

#### Is Marriage of Cousins Dangerous?

In a letter to the medical journals, Prof J B S Haldane states that the Committee on Human Genetics, appointed by the Medical Research Council, has obtained the cooperation of hospitals in an extensive inquiry on the question of the danger of marriages between cousins. All patients in the participating hospitals are being asked whether their parents were related and if so how. The preliminary results are encouraging. Certain rare conditions seem to be rather commoner among the progeny of related than among those of unrelated parents. But the results will not be statistically significant until at least three times the present number of cards have been completed. More data are particularly desired from country districts, where more inbreeding occurs than in towns.

There has long been the belief that human inbreeding is undesirable and some unions of blood relations are forbidden by law. Professor Haldane points out that recent research has shown that certain diseases are much more common among the offspring of blood relations than in the general population. The following percentages of marriages between first cousins have been found among the parents of patients suffering from the following diseases: *xeroderma pigmentosum*, 47; *retinitis pigmentosa*, 27; *juvenile amaurotic idiocy*, 15; *ichthyosis congenita*, 14. But researches into rare diseases gives little idea of the importance of the phenomenon for general health. The fact that the children of first cousins are some thirty times more likely to develop *retinitis pigmentosa* than the general population does not show whether such abnormalities (due to rare autosomal recessive gene substitutions) are sufficiently common to render the marriage of cousins undesirable. Animal experiments give no clear answer. In some species the inbreeding of members of wild populations leads to numerous recessive abnormalities, in others it does not. Hence the need for the present investigation.

#### Air Raid Precautions

The precautions recommended by the government against gas poisoning in air raids have been reported in previous letters. Under the title "Rescue Parties and Clearance of Debris" the Air Raids Precautions Department of the government has issued a memorandum describing the organization recommended for dealing with buildings and roads. It is suggested that this should be attached to the highway department of the local authorities. Whatever area becomes the unit of organization arrangements should be made with neighboring areas for assistance in case of need. Rescue parties should be organized to release persons trapped in damaged buildings. They should consist of six or eight men including a skilled foreman. For a densely populated area three or four rescue parties should be provided for every 100,000 of population (two on duty and two in reserve). Apart from their value in time of war, the memorandum adds persons trained in rescue work might be of value in the case of the collapse of a building in time of peace. Attention is directed to the difficult and dangerous nature of the work, and it is suggested that skilled men should be used in the nucleus of the organization. For training men in the kind of equipment required assistance could be obtained from such local sources as the fire brigade, mine rescue stations, engineering works, and builders and demolition contractors. Some training in first aid and in the use of gas respirators is also suggested. The occupants of property liable to flooding in the event of an air attack should be warned against taking refuge in basements or ground-floor rooms.

#### ANTIGAS INSTRUCTIONS

The government has issued a circular to all the county and borough councils giving the arrangements for a course of instruction at the civilian antigas school to be established at Failfield, Gloucestershire. The government will train instructors at the school, who can be obtained by the local authorities for instruction in their localities. The government will also provide the necessary respirators and protective clothing for local training. The syllabus for the general course will include the principles of civilian antigas precautions, first aid, decontamination and recognition of poison cases. There will also be specialist courses. Each course will as far as possible be composed of persons interested in antigas measures from a common standpoint. Thus separate courses will be provided for instructors primarily concerned in the following duties: (1) police and fire department, (2) first aid, rescue and ambulance work, (3) decontamination of materials, (4) repair of water and gas pipes, cables and wires that may be contaminated by gas. Two specialist courses, each lasting a week, are contemplated at present. One will be for physicians and nurses and will deal with the medical treatment and care of gas casualties. The other will be for the training of chemists in the detection and identification of gases.

#### International Congress of Physical Medicine

The sixth International Congress of Physical Medicine will be held in London from the 12th to the 16th of May. Lord Horder is the president of the British section, Sir Robert Stanton Woods chairman of the executive committee and Sir Henry Gauvain chairman of the general committee. The congress will consist of full members and associate members. Full members will be physicians. Associate members will include medical students, members of the Society of Radiographers, biophysical assistants, state-registered nurses, and members of the Chartered Society of Massage and Medical Gymnastics. Associate members may attend scientific meetings but not take part in discussions. The fee for full membership of the British section is \$10 and for associate members \$2. For foreign members the fees are respectively 250 and 100 Belgian francs. There will be six sections: (1) Kinesitherapy, (2) Physical Education, (3) Hydrotherapy and Climatotherapy, (4) Electrotherapy, (5) Actinotherapy, (6) Radiotherapy and Radium Therapy. The official language will be English, but papers in French, Italian or German will be received. Physicians who wish to take part in the congress should communicate with the honorary secretary, Dr Albert Eidimow, 4 Upper Wimpole Street, London, W 1.

#### Sir Charles Ballance

The death at the advanced age of 79 of Sir Charles Ballance removes a great neurologic surgeon of the past generation, whose scientific activities continued almost to the end. Educated at St Thomas's Hospital, he graduated at London University and obtained gold medals at the B S and M S examinations. In 1895 he was appointed aural surgeon to St Thomas's Hospital and later assistant surgeon and surgeon. He also became surgeon to the Evelina Hospital for Children and to the National Hospital for the Paralyzed and Epileptic, where Sir Victor Horsley was his surgical colleague. His scientific bent was evident from the first. While waiting for practice he began an investigation into the changes in the coats of the large arteries after ligation. The work began in 1885, under the guidance of Professor Birch-Hirschfeld at Leipzig, was continued in London at the Brown Institute, when Horsley was superintendent and was concluded in the medical school of St Thomas's Hospital with the help of Walter Edmunds. The results were published in 1891 under the title "A Treatise on the Ligation of the Great Arteries in Their Continuity, with Observations on the Nature, Progress and Treatment of

Aneurysm" The value of the work was recognized immediately and established its authors in a high position as surgical investigators. In 1919 he published a profusely illustrated monograph, "Essays on the Surgery of the Brain." But his most important researches, based on elaborate experiments, were those on nerve suture and nerve grafting. As early as 1901 he published, in collaboration with Sir James Purves-Stewart, a preliminary work showing the exact process by which peripheral nerves become reunited after division. His indefatigability in pursuing this subject is shown by the fact that as late as 1934 he was writing on the operative treatment of facial palsy. Restrictions on experiments in this country caused him to go to America, where his work on this subject in collaboration with Arthur Ducloux is well known. This was not his first visit, for he had previously worked there with Cushing. He had intimate relations with the Royal College of Surgeons of which he was vice president and where he was a well known figure as a lecturer. Almost to the end he was working at the college laboratories at Down. He was the founder and first president of the Society of British Neurological Surgeons. Other important works from his pen were "Points in the Surgery of the Brain and Its Membranes" and "Essays on the Surgery of the Temporal Bone." His enthusiasm for surgery was such that at the age of 77 he journeyed to Edinburgh and Aberdeen to show his films of experimental nerve anastomosis.

#### PARIS

(From Our Regular Correspondent)

March 29, 1936

#### The Annual French Congress on Hygiene

The twenty second annual meeting of the Societe de medecine publique was held at the Pasteur Institute. The president for 1935 was Professor Lereboullet of Paris. The subjects taken up were infant feeding, hygiene of institutions for nurslings, and social organization for the protection of children.

Jules Renault of Paris discussed the hospitalization of infants. Every hospital should be divided into small wards of ten or twelve beds in order to limit the spread of contagious diseases, which seem to arise no matter what precautions are employed. Secondly, each ward should be divided into cubicles with glass for two thirds of the height of the partition. Each cubicle should be so equipped for heliotherapy that it will not be necessary to move the child. Ample facilities should be afforded for air conditioning, the temperature being maintained constantly at between 70 and 72 F and the humidity between 40 and 70 degrees. These conditions have existed in his service at the Hospital St Louis since 1922 and have resulted in a greatly reduced mortality.

Robert Debre of Paris pleaded for better isolation of nurslings suffering from contagious diseases as well as special training for the nursing personnel in such institutions. Visits from parents and other relatives should be forbidden.

Lereboullet and Bolin stated that the commoner infectious diseases played the most important part in the mortality of children in the first two years. The mode in which the infection is carried is by direct contact. Cassoute of Marseilles stated that as the result of isolation and cubicles the mortality, which had been 53 per cent in 1920 was only 2.32 per cent in 1934.

In the discussion of the second subject organization of protection of infancy, Leclanchie said that this work was now under government supervision instead of being left to private initiative. Those charged to carry out the duty of saving 50,000 infants every year should be impressed with the necessity of prevention as well as assistance.

Hurtado spoke on the coordination of public and private institutions that take care of very young children. Thus far the burden has been borne by private institutions which receive only a pittance from the state. There is still much confusion

as to the work to be undertaken by private and public institutions. The government should not ignore the efforts of non-public institutions. A careful survey should be made of every portion of France and its colonies in order that a better coordination of existing and of desirable resources may be made. Only through team work between government officials and physicians in charge of infant hospitals can progress be made. The social insurance authorities in the Parisian region have confided all work of maternal and infant protection to a special organization, which has been successful in cutting down the mortality.

#### Abuse of Treatment with Gonadotropic Substance in Undescended Testes

In the *Presse medicale*, March 25, Prof. Georges Marion reports a case in which he warns against the use of gonadotropic substances by those whose knowledge of the variations in the mode of descent of the testis is limited. If the testis is simply arrested in its descent, it is found either in the iliac fossa or in the inguinal canal or it has passed through the canal but is arrested in the upper part of the scrotum just distal to the external abdominal ring. Cases in which the testis is unable to migrate to its normal position in the scrotum are the only ones in which one is justified in a trial of non-operative treatment. There is another totally different group of cases in which the testis is not checked in its descent but migrates so that it lies over the symphysis pubis, over the upper femoral region and in the perineum. The case reported by Professor Marion belonged in the second (femoral) subgroup of migrating or aberrant testes. It is useless to treat these cases by the same method as one might employ in arrest of descent. Marion's patient was 15 years of age with marked deficiency in development of the external genitalia and no palpable evidence as to where the testes were located. At operation, the testis on each side was found over Scarpa's triangle and was about the size of a bean. The testes were replaced in the scrotum. Following the operation, inquiry revealed that the boy had been given gonadotropic substance since the age of 10 years. No effort apparently had been made to distinguish between an arrested descent and an abnormal migration of the testis. Professor Marion deplored the fact that the late operation would be of no avail in stimulating the development of the testis, since it is well known that such an organ will not develop unless an operation (orchidopexy) is performed at as early a period as possible before puberty. If the administration of gonadotropic substance has not been followed by complete descent into the scrotum when the boy reaches the age of 10 or 12 years, operation is indicated.

#### A Donor Who Has Given 257 Liters of Blood

A workman, Raymond Briez, in the public markets of Paris, has been the donor of 257 quarts (liters) of blood since 1924. In that year he furnished the blood for four transfusions and in 1925 for thirty-eight. In 1927 the number attained the astonishing figure of ninety-four and from that year to 1935 averaged from fifty to sixty a year. In 1935 there were ninety-eight transfusions in which the blood was furnished by Briez. The average amount for each transfusion was about 10 ounces (300 cc). No ill effects have ever been noted and Briez is always ready for another call.

#### Report of the American Hospital of Paris

At the recent annual meeting of the board of governors of the American Hospital the president, Mr. Arthur T. Kemp, stated that there had been an increase in revenue as compared to the previous year of 230,276 francs (about \$15,000). The revenue from investments showed a decrease of 60,000 francs (about \$4,200). The total operating expenses were 63,000 francs (\$4,500) more than in 1934. Hospital service rendered to patients unable to pay in whole or in part amounted to

916,930 francs (\$61,128) Mr Edward B Close is voluntarily filling the chair of manager, giving all his time to the hospital Dr Edmund L Gros was reappointed chief of the medical staff Dr Thierry de Martel was named chief of the surgical and Dr Lawrence S Fuller chief of the medical service

#### Lectures on Cardiology at Royat

Royat, a city in central France, is the principal resort which specializes in the treatment of diseases of the heart and blood vessels A course of conferences open to cardiologists of all countries will be given May 31 and June 1 under the supervision of a committee headed by Professor Vaquez The other members will be Professors Clerc, Laubry, Castaigne, Lian, Gallavardin and Dumas Among the subjects on which papers will be read, the following are especially to be noted physiology of vascular tonus (Heymans of Ghent, Belgium, and Brouha of Liege, Belgium), cerebral vascular spasms (Riser of Toulouse), vascular spasms of the extremities (Leriche and Fontaine of Strasbourg), vascular spasms in their relation to endocrinology (Marañon and Duque of Madrid, Spain) and treatment of vascular spasms (Loeper of Paris) Cardiologists wishing to attend can secure information through Dr R Boucomont, Royat (Puy de Dome), France

#### Cure of Staphylococcic Septicemia with Staphylococcus Anatoxin

Another instance of the cure of a severe generalized staphylococcic infection was reported at the same meeting by Merklen and his associates A man, aged 33, was admitted Oct 11, 1935, with the clinical picture of the severe septicemia The illness began during August as a deep-seated infection of the right little finger with gradual appearance of the symptoms of a generalized infection On admission the blood culture was found positive for Staphylococcus aureus In addition to six transfusions, eight injections of staphylococcus anatoxin were given In the first two injections 1 cc was employed, but in each of the six others 2 cc was given In spite of secondary complications, such as a pneumonia of the base of the left lower lobe and septic arthritis of the knee, recovery ensued The first negative blood culture was six weeks after admission to the hospital, five of the six previous blood cultures having been positive

#### Prof René Leriche Lecturer at College de France

Owing to the death of Prof Charles Nicolle, two lectures a week are being given by Prof Rene Leriche of Strasbourg, who has chosen as his subject the "Surgery of Pain" This is a subject to which Professor Leriche has devoted the greater part of his experimental research during recent years His clinical work on the surgery of the sympathetic system is familiar to American surgeons

Professor Leriche is at present head of the department of surgery in the medical school at Strasbourg He has as predecessors in the College of France such distinguished men as Laënnec, Magendie and Claude Bernard

#### Professor Nobécourt Promoted in Legion of Honor

February 15 the friends and assistants of the pediatrician Professor Nobécourt presented him with a medal on his recent promotion to the rank of Commander in the Legion of Honor The meeting was held in the lecture room of the Hopital des enfants malades and the services rendered to the development of pediatrics were described by Surgeon General Rouvillois, president of the Academie de chirurgie

#### Antoine Beclère's Eightieth Birthday

The friends and students of the roentgenologist Antoine Beclère presented him with a medal and a book containing a summary of his contributions to his specialty on March 17, his eightieth birthday Professor Beclère is still very active in hospital work and frequently attends medical meetings

## BERLIN

(From Our Regular Correspondent)

Feb 26, 1936

### Discussion of Diabetes

Important problems in the field of diabetes were recently discussed by the Berlin Medical Society Professor Umber, the first speaker, is of the opinion that in diabetes a disturbance in the absorption of sugar in all the organs as well as the disturbance of the formation of glycogen is to be considered This hypothesis is supported by the effect of insulin therapy, which increases the absorption of carbohydrate by the body In 98 per cent of the cases of diabetes it is a question of damage to the islands of Langerhans, while but 2 per cent present extra-insular hyperglycemia In cases of insular insufficiency, the cases of "true diabetes," reaction to insulin is favorable whereas extra-insular glycosuria is not influenced by diet or by treatment with insulin Umber concludes that the mutual hereditary predispositions toward diabetes in a pair of twins result in identical manifestations of the insular type disease, while dissimilarity can be caused only by infectious neglect of the insulin supply and so on Allen's treatment when not too prolonged is still highly efficacious Since continued secretion of sugar, indicative of a high sugar content in the blood, influences the course of the disease most unfavorably, Umber stipulates that in cases of insular diabetes the urine be free from sugar The maintenance of a normal blood sugar content is necessary, however, only if an operation is contemplated, otherwise it may safely be kept at not above 200 mg per hundred cubic centimeters The necessity for insulin therapy should be determined by the remaining amount of insulin produced and by the number of calories supplied One may attempt to replenish the deficient glycogen supply in the liver and musculature of diabetic patients, under the protection of insulin perhaps, by a regimen rich in carbohydrate and deficient in fat In mixed cases of insular and extra-insular diabetes the hope of effecting a favorable influence over the disease by the establishment of slightly soluble deposits of insulin has not been realized These cases cannot, need not, be kept free from sugar

C Brentano of the von Bergmann clinic pointed out that the skeletal musculature is the greatest consumer of sugar and accordingly the greatest consumer of insulin within the human organization The skeletal musculature and not the liver is the true center of metabolic disturbance in diabetes The distressed glycogen condition tests the organism by increasing the blood sugar in order to facilitate the formation of sugar and acetone bodies Treatment formerly was directed at the dead cells presenting unabsorbed sugar of the flooded tissue fluid, at present the living cells, deficient in glycogen, and the muscle cells in particular are observed The organism must be assisted in its struggle to facilitate the formation of glycogen It is here assumed that a provision of the most important building material of glycogen, the carbohydrate of nutrition, is indicated With this in mind the attempt should be made to obtain the best possible carbohydrate balance namely, the greatest possible difference between the amount of carbohydrate ingested as nutriment and the amount of sugar excreted in the urine The fear of glycosuria is unwarranted, the condition is dangerous only as the balance is deficient Glycosuria and the blood sugar do not increase in the same measure as the amount of supplied carbohydrate Improvement of the balance by increased supplies of carbohydrate has, however, its limitation overfeeding both before and after must be avoided While from 36 to 60 Gm of carbohydrate has heretofore been reckoned as sufficient for the diabetic patient, Brentano attempts to maintain balances of from 100 to 250 Gm in his patients The replenishment of the depleted glycogen stock takes place

most rapidly when temporary injections of insulin in increased amounts and a full, free supply of carbohydrate are employed. With this treatment begins a lasting improvement in the patient's metabolism. In serious cases much more carbohydrate is given now than before. A mild accompanying glycosuria is not harmful.

Also observations on diabetes in childhood were made. Umber had stated that, despite the generally severe course taken by the disease, he successfully treated sixty-seven children who were under observation for two years. One other child patient died in coma. The Berlin pediatrician Professor Bessau stressed, however, the unfavorable prognosis when diabetes occurs in childhood. In its earliest stage, childhood diabetes is often accompanied by decrease in the blood sugar. Bessau infers therefrom a defect in the regulating capacity of the pancreas. The nutriment ingested by children undergoing treatment with insulin should amount to 1 Gm of albumin, 4 Gm of fat and 6 Gm of carbohydrate per kilogram of body weight. Any deviation from this proportion has a bad effect on metabolism, reduction of the carbohydrate ration or an increase in fat causes acetonuria. Since fatalities due to hypoglycemic action occasionally occur among children as late as eight hours after the injection, Bessau considers administration of insulin in the afternoon distinctly contraindicated.

### The Selection of Secondary School Pupils

Health service for the German secondary schools (gymnasien, realgymnasien, realschulen) came to be regarded as important only following the World War. Decades before the Breslau professor of ophthalmology Hermann Cohn had called attention to the prevalence of myopia, particularly among the secondary school population, and at the same time raised the question of school health in general. Today, by careful selection, all but the mentally and physically fit are refused admission to the secondary schools. In March 1935 the national minister of education decreed that young persons afflicted with presumably incurable disorders which impair the vital forces as well as carriers of hereditary disease shall no longer be accepted in the secondary schools. In doubtful cases official medical opinion must be consulted. Young persons who show a stubborn aversion to cleanliness and those who by nonparticipation in physical exercise exhibit "an unwillingness to achieve physical hardihood" are subject to expulsion unless express recommendation that they be permitted to remain is made by both the official physician and the instructor in athletics. Physical exercise thus receives stronger emphasis than before although previously it had been possible in case of total failure in sports and calisthenics to withhold the certificate of fitness for the university.

The national minister of the interior has established certain guiding principles that are to be considered authoritative for health supervision in secondary schools. The public health officers are as yet (up to the time of the general rearrangement of the school medical service) responsible for physical examinations of secondary school pupils.

The guiding principles differentiate candidates as completely conditionally and temporarily unfit for admission.

To the first group belong all those afflicted with mental or physical defects that presumably will later prove obstacles to the proper training for and practice of a profession. Among such disqualifying defects and diseases are badly decompensated heart conditions, severe asthma, chronic kidney disorders, marked defects of the eyes and ears as well as serious impediments of speech resulting from cleft palate or diphtheric crippling, severe organic nervous defects and similar disturbances of the endocrine system, schizophrenia, the milder types of feeble-mindedness and moral delinquency.

Certain diseases classify the candidate as fit on condition for example epilepsy, manic depressive insanity, psychopathic

states, sexual degeneracy and narcotic intoxications. Classified as temporarily unfit are those presenting offensive diseases such as chronic extensive eczema or acute syphilis with cutaneous phenomena, also disturbances that can be easily imitated by others, chorea minor for example, and, finally, ephemeral psychic disturbances that are manifestations of psychoses caused by intoxications, infections or trauma, provided such will not lead to permanent alterations of character.

### Jewish and Non-Aryan Physicians in Germany

In the Nuremberg Laws the terms "Aryan" and "non-Aryan" are abandoned and henceforth the differentiation shall be as between Jewish and non-Jewish physicians. The following are classified as Jewish physicians: (1) full Jews (persons descended from four Jewish grandparents), (2) three-fourths Jews (having three Jewish grandparents), (3) half Jews (having two Jewish grandparents) who on Sept 16, 1935, were members of the Jewish religious community or who subsequently have assumed such membership and, in addition, half Jews who, as of the foregoing date, had contracted marriage with a Jew (or Jewess) or who subsequently have contracted such marriage. All other physicians are collectively classed as non-Jewish.

Non-Jewish physicians must not permit Jewish physicians to serve in their stead nor shall they themselves substitute for Jewish physicians. This rule may be abrogated in exceptional emergency cases by the physicians of the insurance practice. Similar provisions regulate the employment of consultants and assistants. Non-Jewish physicians must refer their non-Jewish patients only to non-Jewish specialists or hospital physicians and vice versa. On the other hand, non-Jewish physicians (in particular, those connected with hospitals and sanatoriums) must receive patients referred by Jewish physicians if the professional circumstances appear to warrant such action. Consultants are under the same obligation. This provision is designed primarily to aid persons entitled to government insurance benefits (sick insurance, invalid insurance and so on).

The new regulation in no way changes the nonadmittance to practice of new physicians of non-Aryan descent and those Aryan physicians who are married to non-Aryans. These have not been admitted to the insurance practice since May 17, 1934. They will not be allowed to practice (as the *reichsarzteordnung* stipulates) so long as on the date of application for admittance the proportion of physicians of other than German (non-Aryan) blood exceeds that of the non-German citizens to the entire population. As non-Germans are classified all persons not descended from four grandparents of German (Aryan) blood.

### Organization for New "German Medicine"

In April the newly established National Organization for New German Medicine' (*Reichsarbeitsgemeinschaft für eine neue "Deutsche Heilkunde"*) will hold its three day national convention at Wiesbaden. Among the announced lecture topics the following may be mentioned: "Paracelsian Thought Within the Bounds of New German Medicine," "Morphologic Foundations of Biologic Thought in Medicine," "Influence of Institutional Treatment on the General Condition and Attitude of the Patient" and "The Clinical Function of Conscience." A layman Wegener, a member of the Expert Advisory Public Health Council and director of the National Federation of Associations for Life and Therapeutic Method in Conformity with Nature will discuss "What Relationship Exists Between the Popular Healing Movement and New 'German Medicine'."

The Congress of Internal Medicine, the first session of which will be held in conjunction with the foregoing organization will be addressed on similar subjects, for example, "Nature Medicine Within the Bounds of Academic Medicine," "New German Medicine-Physician and Graduate Study," and "Scientific Nature Medicine."

**BUENOS AIRES***(From Our Regular Correspondent)*

March 5, 1936

**Antidiphtheritic Vaccination**

Dr Alfredo Sordelli, director of the Instituto Bacteriologico of the National Department of Hygiene, lectured before the Academia Nacional de Medicina of Buenos Aires, Oct 24, 1935, on results obtained by workers in the institute on the preparation of an antidiphtheritic vaccine from a toxoid activated by aluminum oxide. A single injection of 2 cc of the vaccine produced immunization in from 93 to 96 per cent of 6015 children who have been vaccinated. The injection is given in the subcutaneous cellular tissues of the infrascapular region. Local and general reactions were slight.

**Society Reunion**

The Sociedad de Patologia of the northern region of Argentina at its ninth reunion in Mendoza province, Oct 1, 1935, discussed the subject of American trypanosomiasis. Homage was paid to the memory of Dr Carlos Chagas, the discoverer of *Schizotrypanum Cruzi*. More than thirty cases of American trypanosomiasis have been discovered in Argentina, scattered all over the country. Acute forms of the infestation have been seen in small children. In all cases there were palpebral edema and unilateral conjunctivitis (Romaña's sign) which, probably, is the port of entry of the infestation. Cases of trypanosomiasis in animals have been seen in different parts of the country. Dogs, armadillos, ferrets, foxes and bats are the animals which up to now have been found to be naturally infected.

**Disturbances Among Students**

There have been some disturbances among the students of the Faculties of Medicine of Buenos Aires and Cordoba. In the faculty of Buenos Aires the students asked for the resignation of two professors. One resigned, as well as the dean and the board of directors. A new directive board was elected and Dr Jose Arce was appointed dean of the faculty. The new board of directors asked the other professor to resign and granted all the requirements made by the students. September 10 the dean left for a trip to Chile, Peru, Mexico, the United States and Cairo. In the faculty of Cordoba the students forced the resignation of the professors who represented them before the board of directors of the faculty.

**Appointments**

Prof A Sordelli was appointed a member of the Committee of Hygiene and Public Health of the League of Nations.

Dr Ernesto Merlo was appointed professor of semeiology at the Faculty of Medicine of Buenos Aires to succeed Dr C Bonorino Udaondo, who resigned.

Drs Julio Diez, L Rabuffetti and J Hanon were appointed associate professors of surgery, clinical medicine and clinical neurology, respectively, at the Faculty of Medicine of Buenos Aires.

**Institute of Clinical Physics**

The senate passed a bill whereby 150,000 Argentine pesos (about \$42,000) will be allowed yearly for the upkeep of a national institute of physics applied to human pathology. Dr Mariano R Castex has been appointed director.

**Professor Houssay Returns**

Prof B A Houssay has returned to Argentina after a voyage during which he gave twenty-eight lectures as follows: one in Cambridge, England, three in France, nineteen in the United States, two in Canada and three in Brazil. In the United States he gave the Dunham lectures at Harvard, the Hanna lecture in Cleveland, the Lane lecture in San Francisco, the Herter lecture at Johns Hopkins, the Harvey lecture in New

York, the Eastman lecture in Rochester and several other lectures in the University of California, Stanford University, the University of Chicago, the University of Pennsylvania, Yale and the Academy of Medicine of Los Angeles and of San Diego, and the American Association for the Advancement of Science.

Prof B A Houssay was given the honorary degree Doctor honoris causa of the University of Paris, Nov 9, 1935, in the Sorbonne amphitheater.

**Prizes Awarded**

Prizes given for the best theses presented during 1934 were awarded to Dr L Leloir for his work on suprarenals and metabolism of carbohydrates, Dr E Capdehourat for his work on cyanosis in Ayerza's disease, and Dr E Braun Menendez for his work on diencephalon, hypophysis and arterial pressure.

Dr Julio Diez was recently given the first national prize of sciences for 1931 for his work on surgery on the sympathetics in vascular disturbances. The prize is 30,000 pesos (about \$9,500).

Dr P Pavlovsky was given the P Palma prize of 10,000 pesos (about \$2,800) for his work on diagnosis by means of ganglionic puncture.

**Honors Bestowed**

At a public gathering recently in Buenos Aires Dr A H Roffo was rendered homage for his twenty-five years' work in the study of cancer. A plate was unveiled in the Instituto Bacteriologico of Buenos Aires, Nov 23, 1935 in memory of Prof R Kraus, the founder of the institute at its present location. A mural plate was recently unveiled in the Facultad de Medicina of Buenos Aires in honor of Prof Luis Guemes.

**Deaths**

Dr Rodolfo A Rivarola, associate professor of orthopedics and director of the Hospital de Niños, died, Dec 5, 1935.

Dr Pedro B Aquino, physician of the Hospital Alvear, died, Oct 12, 1935.

Dr Francisco de la Torre, professor of therapeutics and ex-dean of the Faculty of Medicine of Cordoba, died, Nov 17, 1935.

Drs Fernando Ruiz and Artemio Zeno, professors of pathologic anatomy and of clinical surgery at the Faculty of Medicine of Rosario, died, Nov 17, 1935.

Dr S Madrid Paez, director of the Casa de Expositos, died, January 16.

Dr Juan Busco, a well known pediatrician, died, January 26.

---

**Marriages**

---

OSCAR HUGH FULCHER, Welch, W Va., to Mrs Irene Pendleton Moorman at Princeton, March 3.

SAMUEL EUGENE MILLER, Pauline, S C., to Miss Elizabeth M Barnwell of Rockville, March 10.

WALTER G STUCK, San Antonio, Texas, to Miss Mary Eleanor Buck of Chicago, March 28.

GEORGE A FIEDLER, New York, to Miss Elinor Marie Cummings of Toronto, Ont., March 14.

JOHN A SIMMONS, Arcadia, Fla., to Mrs Erma T Lambert of Columbia, S C., February 18.

WILLIAM RUDOLPH HANSA, Iowa City, to Miss Doris Sanborn of Scotia, Neb., recently.

C KEITH BARNES, Williston, N D., to Miss Margaret Skudstad of Chicago, March 17.

FRANZ RENE MURAD to Miss Priscilla Godfrey Merrill both of New York at Bedford, N Y in February.

SAUEL E WIDNER, Lexington, Neb., to Miss Lily E Willis of Detroit, recently.

JOHN M RUSSELL to Miss Elsie Klooz, both of Youngstown, Ohio, February 27.

## Deaths

**Harlow Brooks** ☉ New York, professor emeritus of clinical medicine, New York University College of Medicine, died, April 13, following an operation for abscess of the liver, aged 65. Dr Brooks was born in Medo, Minn, March 31 1871. After attending schools at Mapleton, Minn, and the University of Oregon, he went to the University of Michigan Department of Medicine and Surgery, Ann Arbor, where he graduated in 1895. He studied at the University of Freiburg in Germany in 1898 and at the Polyklinik in Munich in 1901. In 1894 he was assistant demonstrator of anatomy at his alma mater. From 1895 to 1898 he was an instructor in histology and embryology at the Bellevue Hospital Medical College, New York, later known as the New York University and Bellevue Hospital Medical College. He was an instructor and assistant professor of pathology and special pathology from 1898 to 1900, assistant professor of clinical medicine from 1904 to 1911 and later professor of clinical medicine. Dr Brooks served as a captain in the army medical department during the Spanish-American War. In 1917 he served as a major in the World War in command of the Base Hospital at Camp Upton, Yaphank, L I. In 1918 he was promoted to lieutenant colonel in the United States Army and went to France where, after serving as chief consultant in medicine to two armies, was appointed chief surgeon of the Second Army, American Expeditionary Forces. He was awarded the Distinguished Service Medal. Since 1919 he had been a colonel in the U S Army Reserve Corps.

In 1916 Dr Brooks was a member of the House of Delegates of the American Medical Association. He was a member of the American Gastro-Enterological Association and the Association of American Physicians, and a past president of the American College of Physicians and formerly vice president of the New York Academy of Medicine. He served also as chairman of the program committee of the Pan American Medical Association. He was a trustee of the New York Pathological Society and in 1934 honorary police diagnostician of New York City. Dr Brooks was visiting physician to the City Hospital, consulting physician to the Montefiore Hospital, New York Polyclinic Hospital, Fifth Avenue Hospital, Beth Israel Hospital, Union Hospital and the French Hospital, New York, Ossining (N Y) Hospital, Greenwich (Conn) Hospital, Hekensack (N J) Hospital, Mount Vernon (N Y) Hospital, St John's Hospital, Yonkers, and the Beth Israel Hospital, Newark, N J. He was the author of many monographs and special articles on medical, biologic and ethnological subjects and was interested in animal life, exploration and mountaineering. Honorary fellowship was awarded to him by the New York Zoological Society. In 1929 he was awarded an honorary Master of Science by the University of Michigan. He was much sought as a clinical teacher by many medical organizations. As a worker he was indefatigable and his geniality won him innumerable friendships among his colleagues.

**William Bradley Coley** ☉ New York, Harvard University Medical School, Boston 1888, widely known for his work and reports on the treatment of sarcoma by means of erysipelas and prodigious toxins, formerly professor of clinical surgery, Cornell University Medical College, instructor of surgery, New York Post-Graduate Medical School and Hospital 1890-1897, clinical lecturer in surgery, Columbia University College of Physicians and Surgeons 1898-1908 and associate 1908-1909, member of the American Surgical Association, Southern Surgical Association and the Radiological Society of North America, honorary member of the Association of Surgeons of Great Britain and Ireland, honorary fellow of the Royal College of

Surgeons of England, fellow of the American College of Surgeons, author of the chapter on hernia in various systems of medicine and surgery, chief surgeon to the Mary McClelland Hospital, Cambridge, consulting surgeon to the Physicians Hospital, Plattsburg, Fifth Avenue Hospital and Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York, and the Sharon (Conn) Hospital, surgeon in chief emeritus to the New York Society for the Relief of Ruptured and Crippled, where he died, April 16, aged 74, following an operation for an intestinal infection.

**Theodore Le Boutilier** ☉ Philadelphia University of Pennsylvania Department of Medicine, Philadelphia, 1898, formerly clinical professor of pediatrics, Woman's Medical College of Pennsylvania, Philadelphia and assistant professor of epidemic contagious diseases, University of Pennsylvania Graduate School of Medicine, served during the World War, past president of the Philadelphia Pediatric Society, on the staffs of the Philadelphia General Hospital and the Philadelphia Hospital for Contagious Diseases, aged 59, died, March 4, in the University of Pennsylvania Hospital.

**Robert Davies Rhein**, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1901, member of the Medical Society of the State of Pennsylvania for many years on the staffs of the Howard Hospital, American Hospital for Diseases of the Stomach and the Philadelphia General Hospital, physician to the Home for Incurables, aged 69, died, February 1, in the Graduate Hospital of coronary thrombosis.

**Marcus Polk Smartt**, Austin, Texas University of Dallas Medical Department 1902, served during the World War, county health officer, formerly director of communicable diseases state department of health, aged 64, died February 5 in a local hospital, of pneumonia.

**George Washington Williamson**, Hartford, Ala., Medical College of Alabama Mobile, 1893, member of the Medical Association of the State of Alabama, past president of the Geneva County Medical Society, aged 72, died, January 29, of cardiorenal disease.

**Daniel Guy Mills** ☉ McCallsburg Iowa State University of Iowa College of Medicine Iowa City, 1896, for many years county coroner, aged 74, died, January 28, in the Iowa Sanitarium and Hospital, Nevada, of carcinoma of the gallbladder.

**Aloys Iberler**, Pittsburgh, Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1925, aged 40, resident physician to St Francis Hospital, where he died, February 12, as the result of a skull fracture received in a fall.

**Ferdinand Wilhelm Vowinkel** ☉ San Francisco, Medizinische Fakultät der Friedrich-Wilhelms-Universität, Berlin Prussia, Germany 1885, served during the World War, aged 74, died, February 24, in the University of California Hospital.

**Louis F Ankrum** ☉ Pittsburgh, College of Physicians and Surgeons Baltimore 1886, aged 78, died, January 25, in the Western Pennsylvania Hospital of bronchopneumonia, following fracture of the pelvis due to a fall on an icy sidewalk.

**Webster Stanley Smith** ☉ Dayton Ohio, Medical College of Ohio Cincinnati, 1880, past president of the Montgomery County Medical Society, aged 79, on the staff of the Miami Valley Hospital where he died, January 30, of arteriosclerosis.

**Murray Morris Levy**, Portland Ore, University of Oregon Medical School, Portland 1917, member of the Oregon State Medical Society, clinical instructor in medicine at his alma mater, aged 50, died, January 24, of coronary sclerosis.

**William Moran**, Portland Maine, Vanderbilt University School of Medicine Nashville Tenn 1901, member of the Maine Medical Association, formerly on the staff of the Maine Eye and Ear Infirmary, aged 73, died, January 30.

HARLOW BROOKS, M D 1871-1936

Charles C McClendon, Galveston, Texas, Meharry Medical College, Nashville Tenn, 1905, aged 55 died, January 20, in the Los Angeles General Hospital, of coronary thrombosis and diabetes mellitus

Clayton Elmer Bartlett, Aberdeen, Wash., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905, aged 55, died suddenly, January 14, of heart disease

Roddie J Hamilton, Springfield Ky., University of Louisville (Ky.) Medical Department, 1891, member of the Kentucky State Medical Association, aged 68, died, January 25, of cerebral hemorrhage

Jefferson T Novinger, Westmount, Que., Canada, Hahnemann Medical College and Hospital, Chicago 1903 formerly on the staff of the Homeopathic Hospital, Montreal aged 58 died, January 20

Robert Samuel Frost, Kinnmount Ont Canada M.D., Victoria University Medical Department Coburg 1881 M.B. University of Toronto Faculty of Medicine 1882 aged 83, died, January 24

Arley Ernest Carlock, Hartshorne Okla. Missouri Medical College, St Louis, 1897, member of the Oklahoma State Medical Association, aged 62, died January 10 of coronary thrombosis

Guy Huffman Rothfuss, Williamsport Pa. New York University University and Bellevue Hospital Medical College 1933, aged 31 was killed January 30 in a railroad accident in Sunbury

Robert H Greene, Hagerman Idaho St Louis College of Physicians and Surgeons 1896 member of the Idaho State Medical Association, aged 71, died January 21 of paralysis agitans

Lewis W Watkins, Leonard Texas Memphis (Tenn.) Hospital Medical College 1903, aged 60 died January 5 in the Baylor University Hospital, Dallas of bronchopneumonia

Carolus Melville Cobb, Lynn Mass University of Vermont College of Medicine Burlington 1883 member of the Massachusetts Medical Society, aged 74 died January 2

Francis Joseph Meek, Shamokin Pa. Jefferson Medical College of Philadelphia 1892, member of the Medical Society of the State of Pennsylvania, aged 68 died January 24

Willie Paxton Holloway, Maud Texas Memphis (Tenn.) Hospital Medical College, 1912, served during the World War aged 49 died, February 13 of cerebral hemorrhage

David Wenger Ensminger, Mount Aetna Pa. Hahnemann Medical College and Hospital of Philadelphia 1902 aged 73, died, January 15, of chronic myocarditis

Martin L Brodie, Corinth, Ky. University of Tennessee Medical Department, Nashville 1889 aged 77 died suddenly January 23 of myocarditis and arteriosclerosis

Henry Carlyle Randle, Portland Ore. Willamette University Medical Department, Salem 1907 aged 60 died January 19, of myocarditis and aortic insufficiency

Robert Scrivner Lipscomb, Grapevine Texas Tulane University of Louisiana Medical Department New Orleans 1888 aged 76, died January 26, of pneumonia

William Harvey Clarke, Fruitdale Ala. Medical College of Alabama Mobile, 1894, aged 70 died January 26 in the Mobile (Ala.) Infirmary, of pneumonia

Morgan Wilson Knerr, Coplay Pa. Bellevue Hospital Medical College New York 1891, aged 71 died January 13 of prostatic hypertrophy and uremia

Abraham Moss, Brooklyn, Cornell University Medical College, New York 1903, formerly on the staff of the Broad Street Hospital, aged 53, died, January 19

Allen J Trail, McMinnville Tenn. University of Tennessee Medical Department, Nashville 1895 aged 75 died January 19, of coronary thrombosis

Thomas Jefferson Dodson, Foss Okla. University of Tennessee Medical Department Nashville, 1891 aged 73 died January 13 of chronic myocarditis

William Cannon Cahall Philadelphia Jefferson Medical College of Philadelphia 1879 aged 78 died January 24 in Allenwood Pa. of tuberculosis

John G Sharp Francis, Okla. (licensed in Oklahoma under the Act of 1908), member of the school board aged 64 died January 10, of angina pectoris

Alexander Allen Forbes North Vancouver B.C. Canada University of the City of New York Medical Department 1883, aged 85 died, Dec 4 1935

Jesse J Fouts, Gonzales, Texas, Tulane University of Louisiana Medical Department, New Orleans, 1888, aged 11, died, January 15, of uremia

Irving Harold Blue, Sanford, N.C., Meharry Medical College, Nashville, Tenn. 1924, served during the World War, aged 39, died, January 23

Bernard P Garred, Charleston W. Va., College of Physicians and Surgeons, Baltimore, 1883, aged 77, died, January 19, of coronary occlusion

Thomas P Crawford, East Liverpool, Ohio, University of Wooster Medical Department, Cleveland, 1877, aged 83, died, in January, of senility

William A Hall, Prairie Du Chien Wis., Louisville (Ky.) Medical College, 1877, aged 85, died, January 27, of psychonephritis and uremia

George Louis Marion, Mountain View, Calif., Rush Medical College, Chicago, 1886, aged 70, died, January 27, of coronary thrombosis

Alcinda Auten Pine, South Pasadena Calif., Woman's Medical College Chicago 1882, aged 77, died, January 19 of chronic myocarditis

John Samuel Gale, Tampa Fla. University College of Medicine Richmond, Va., 1907 aged 53, died, January 16, of coronary occlusion

William E Mack, Paradise, Calif. Cincinnati College of Medicine and Surgery 1884, aged 79, died, January 31, of chronic myocarditis

Abigail Grace White, Bradford, Pa., Homeopathic Hospital College Cleveland 1887, aged 82, died, January 13, of chronic myocarditis

Louis Lynn Walls, Los Angeles, Chicago College of Medicine and Surgery 1910, aged 60 died, January 26, of coronary occlusion

Robert Dunn Davis Okla. Southwestern University Medical College Dallas, 1904, aged 55, died, January 19, of coronary occlusion

Robert M Drummond, Russellville, Ark., Vanderbilt University School of Medicine Nashville, Tenn., 1881, aged 79, died January 14

James Fulton Burnam, Madison, Ala., University of Nashville (Tenn.) Medical Department 1899, aged 59, died, January 1 in Huntsville

Louis Prentiss Bethel, Columbus Ohio, Cleveland Medical College 1892 also an orthodontist, aged 76 died, January 17, of heart disease

Robert Carroll Hiscock, Kingston, Ont., Canada Queen's University Faculty of Medicine, Kingston, 1900, aged 60 died January 20

DeLacy Evelyn Wyman, Lena, S.C. University of Georgia Medical Department Augusta, 1900, aged 59, died January 24

Gabriel N Tinsley, Bowling Green Mo. Missouri Medical College St Louis 1879, aged 77, died, January 5, of angina pectoris

George E Goodwin, Vidmore, Okla. Baltimore Medical College 1896, aged 67 died January 18, of cerebral hemorrhage

John Alexander Graham Barstow Calif. Chicago College of Medicine and Surgery, 1915, aged 58, died, January 2

J R Levy, Florence S.C., College of Physicians and Surgeons of Chicago 1894 aged 73, died suddenly, January 21

Lewis Wetzel Spradling, Athens, Tenn., University of Nashville Medical Department, 1899, aged 68, died, January 1

Harry M Pierce, St Petersburg Fla. St Louis Medical College 1887 aged 74, died recently of cardiovascular disease.

Otho D Porter, Bowling Green, Ky. Meharry Medical College Nashville Tenn, 1894 aged 71, died January 21

Richard Stillwell Holman St Louis, Bellevue Hospital Medical College, New York 1882 aged 77, died, January 7

Henry Albert Zininger Hartsville, Ohio, Starling Medical College Columbus, 1892, aged 72, died January 20

Oran Cortez Holt, San Antonio, Texas, Illinois Medical College, Chicago, 1903 aged 53, died January 24

Herbert J Stevens, Titusville Fla. Ohio Medical University Columbus 1893, aged 65 died, January 3

Abram Smith Dyer, Tell City, Ind. (licensed in Indiana in 1897) aged 85 died recently

## Correspondence

### NERVOUS COMPLICATIONS FOLLOWING SPINAL ANESTHESIA

*To the Editor*—Some comment is necessary on the article on nervous complications following spinal anesthesia by Brock, Bell and Davison, which appeared in *THE JOURNAL*, February 8.

There are several statements that to me are basically not quite accurate. The first sentence in the paragraph headed "Comment" reads "In all but one of these cases the cocaine derivative used was well known, two received a preparation of procaine with strychnine sulfate, three nupercaine and one procaine hydrochloride." This sentence is inaccurate. Procaine hydrochloride and nupercaine are two entirely different chemical compounds and neither is derived from cocaine.

Further along, they state "In all of the cases but one, the neural syndromes so speedily followed the administration of the spinal anesthesia as to suggest immediately a direct chemotoxic effect of the cocaine derivatives on the neuraxis. It must be emphasized however, that the direct toxic effect does not entirely explain the causation of the neural complications." It is difficult to understand how the writers can speak of the chemotoxic effect of the cocaine derivatives when, in fact, they are dealing with three different chemical compounds.

In the closing paragraph the authors state, "it should be noted that allergic factors are not involved in these cases, since one is not dealing with protein sensitization." I fear the possibility of an allergic factor is too lightly dismissed and why the authors do not recognize that substances other than protein may be responsible for an allergic reaction I am at a loss to understand.

A. L. SCHWARTZ, M.D., Cincinnati

### ELECTROCARDIOGRAPHIC STUDIES DURING ANESTHESIA

*To the Editor*—In the discussion on the article entitled "Electrocardiographic Studies During Surgical Anesthesia" (*THE JOURNAL*, February 8, p. 434) occur the words even though ventricular fibrillation has not been demonstrated in man. Perhaps some words have been deleted and Dr. M. J. Raisbeck did not intend to make his statement so final. The chapter on ventricular fibrillation in my book (*The Heart in Modern Practice*, ed. 2, 1928) contains a reproduction of an electrocardiogram in a patient and references to various reports in the literature, additional articles regarding the occurrence of this arrhythmia have appeared in subsequent medical journals.

The electrocardiogram figure 5, record C, in the article appears to depict a transition to paroxysmal tachycardia, of ventricular origin with alternation in the direction of the ventricular deflections. This is more dangerous than the mere occurrence of extrasystoles. I have discussed its significance elsewhere (*Ventricular Fibrillation Following Ventricular Tachycardia*, *Boston M & S J* 190:687 [April 24] 1924). In brief, the literature of cardiology contains articles on these subjects.

WILLIAM D. REID, M.D., Boston

[A copy of Dr. Reid's communication was submitted to Dr. Raisbeck, who replies.]

*To the Editor*—The point in this comment is well taken and represents my own opinion in the matter. I should have said that ventricular fibrillation has only rarely been demonstrated in man.

In the course of this impromptu discussion I wished to emphasize the fact that ventricular tachycardia is closely related to ventricular fibrillation and that in the state of our present

knowledge ventricular fibrillation ends fatally in the vast majority of cases. I am well aware of the reports in the literature concerning recurring attacks of ventricular fibrillation which have been recorded and followed by recovery, in the sense that the mechanism reverted to normal.

There will probably be an analogy here in the change of opinion concerning auricular fibrillation. It was a common belief that auricular fibrillation persisted indefinitely when once started until more frequent records brought home the fact that the paroxysmal type is far more common than we originally suspected. In the future we may by dint of frequent records be able to demonstrate an increasing number of cases of ventricular fibrillation followed by recovery.

The fact remains that my statement as printed was incorrect and I accept the correction gladly.

MILTON J. RAISBECK, M.D., New York

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

### TOXICITY OF DINITROPHENOL

*To the Editor*—I am writing concerning one of my patients who has become poisoned by taking dinitrophenol tablets at the advice and under the direction of her druggist. The patient is a woman aged 28 and married. The weight is 177 pounds (80 kg), temperature 98.6, pulse 100, respiration 40. About Jan. 1, 1935, she purchased 1 grain (0.065 Gm.) dinitrophenol tablets. Her druggist told her to take one tablet three times a day and to watch for an elevation of temperature and if this occurred to stop the tablets for a while. Several times she noted that her temperature would rise and she would stop taking the tablets for a day. When the temperature again became normal she would resume taking the tablets, sometimes taking 2 grains (0.13 Gm.) three times a day to make up for the lost time. The daily dose varied from 3 to 6 grains (0.2 to 0.4 Gm.). After taking a total of 100 grains (6.5 Gm.) as a first course she noted a small fibrous tumor growing under the mucous membrane of the left lower eyelid. It was also noted at this time that she was having difficulty in seeing objects clearly for an hour or so after awakening in the morning. Observing these symptoms she decided to stop the tablets. After a lapse of three weeks she resumed the taking of dinitrophenol and consumed 150 one grain tablets at the rate of 3 grains a day. This made a grand total of 250 grains (16.25 Gm.) of dinitrophenol which this patient has taken. She states that she has not taken any since August at which time I first saw her and advised her to stop. A few days ago she again visited me saying that she was very nervous, had had several fainting spells during the summer and had attacks when her face would become very flushed and she would become quite warm. Her hair is becoming loose and is falling out rather rapidly. Three weeks ago the lower left second molar tooth began to crumble and is now almost entirely gone except for the roots. The tumor under the mucous membrane of the left eyelid is a little larger. She cannot sleep well at night although she is tired almost all the time. She has noted a partial suppression of urine and is able to retain it for one and one-half days and then passes only a small amount. The urine is normal in color and negative for sugar and albumin. I have read three reports in *THE JOURNAL* in which death occurred rather quickly but have been unable to find much on the treatment of the condition. I would appreciate any information you have on treatment. I should like to have details of the Berrien test of the urine. Do you think these symptoms and pathologic changes could appear after the drug had been discontinued for two months? What is the prognosis? Has the minimum lethal dose been determined for human beings? I see in *THE JOURNAL* that the minimum lethal dose for animals is 3 mg. per kilogram.

J. S. CALDWELL, M.D., Cincinnati

*ANSWER*—In view of the nature and variety of harmful effects of dinitrophenol that have been and continue to be reported in the literature, there is no reason for doubting that the patient is suffering from the after-effects of this drug, even though its administration was stopped two months ago. The prognosis should be cautious since the patient probably sustained severe damage to the liver and kidneys from which she is apparently slow in recuperating. At our present state of knowledge of the toxicology of dinitrophenol it is difficult to interpret the symptoms of which the patient is now complaining. A basal metabolism and a liver function test at this time might be informative.

The minimum lethal dose of dinitrophenol for animals is supposed to range from 20 to 30 mg. per kilogram of body weight. As little as 10 mg. per kilogram, however, is con-

sidered to be too dangerous for routine use in man. The dose recommended for human beings by the protagonists of the drug is 5 mg per kilogram. However, at least one person out of seven is sensitive to the material and cannot tolerate even much smaller amounts than the recommended dosage. Even the greatest dose that the patient took ( $6 \text{ grains} \times 60 = 360 \text{ mg}$ ), for instance, is below the recommended level ( $80 \text{ Kg} \times 5 = 400 \text{ mg}$ ).

For a recent summary and bibliography on this subject, the inquirer is referred to the report of the Council on Pharmacy and Chemistry in *THE JOURNAL*, July 6, 1935, page 31.

Derrien's test for urine consists in determining the ratio

Formaldehyde nitrogen  
Hypobromite nitrogen

The nitrogen determined by the formaldehyde method represents chiefly the ammonium salts and also amino acids, if any of the latter are present. The nitrogen determined by the hypobromite method represents chiefly urea. The normal value of this ratio varies around 6/100, depending somewhat on the diet and on the individual. The ratio is raised by acid ingestion, in the acidosis of starvation or hyperemesis gravidarum, in diabetic ketosis and in hepatic insufficiency. The ratio is lowered by an alkali residue diet or alkali administration, and in acidosis of renal origin. A discussion of the interpretation of this test may be found in the *Montpellier medical* 6/34 (June 15) 1934.

#### RUBBING LINIMENT

To the Editor—As a camp surgeon in a CCC camp it has been necessary for me to find a good rubbing liniment for the many aches and pains of the boys. I have been making it up as a grand melange of soap water, alcohol, turpentine, ether and chloroform. The only trouble is that there is very little heat in the mixture. I attempted to make up a compound mustard liniment according to the Epitome of the U. S. P. and V. F. Although instructions read for oil of mustard 3 per cent I used an ounce (30 cc) of synthetic oil of mustard to a quart (liter) of a mixture of 300 cc of castor oil and 700 cc of 90 per cent ethyl alcohol; the resulting mixture did not have any heat in it. I then put a drop of the synthetic oil of mustard on my skin and I got only a faint sensation of heat. You will notice that I left out mezereum, menthol and camphor because I felt that the principal thing was the oil of mustard and vehicle. Feeling that the trouble was in the so-called oil of mustard I spoke to the local druggist who had sold it to me. He got another bottle of the oil and made the liniment up in the proper proportions except that he did not put in fluidextract of mezereum as he did not carry it and I did not want to put him to extra expense. The result was the same as before. In view of the fact that this is supposed to be the most powerful mixture of all and since the omission of mezereum did not explain the failure I am writing to you. If published kindly omit name. MD Virginia

ANSWER—It is an error to omit the fluidextract of mezereum, as it adds decidedly to the stinging effect of the liniment. One might, if it is desired to make the preparation still "hotter," double the quantity of the volatile oil of mustard.

A preparation made by extracting powdered capsicum, say 10 per cent, with red oil of camphor is reported to be similar to the proprietary liniment.

#### INTRA UTERINE PRESSURE DURING LABOR PAINS

To the Editor—I am interested in obtaining information regarding intra uterine pressure during labor pains. MD New York

ANSWER—Schatz (*Arch f Gynak* 3/58 1872) recorded the changes in intra-uterine pressure during the process of delivery. He introduced a colpeurynter balloon into the uterus, filled the balloon with water and connected it by means of a tube with a T-cannula, which in turn was connected with two mercury manometers. One manometer recorded the uterine contractions on the drum of the kymograph and the other one helped in the standardization of the pressure values.

Several years later Pouillet (*Arch de tologie* February 1880) constructed the so-called tocograph, an instrument that called for the introduction of a bag into the uterus as well as into the rectum. Other methods were devised by Polailon (*Arch de physiol* 1880 n 1) Acconci (Sulla contrazione e sull'energia dell'utero Turin 1891), Dohnhoff (*Arch f Gynak* 42/335 1892) and Westermarck. Literature on these methods is cited in Westermarck's article on page 332 of the *Skandinavisches Archiv für Physiologie* volume 4 published by Veit & Co, Leipzig in 1893.

Westermarck in 1893 pointed out the disadvantages of the methods reported by Schatz and Polailon. He devised a new method which employs a uterine catheter and a bag. The catheter permits the introduction of the bag into the uterus and also forms the connection between the bag and the tube that connects the instrument with the manometer. The catheter makes it possible to fill the bag with water outside the uterus.

The catheter must be pliable so that it will lie close to the head of the child when the head passes through the pelvis. It should of course not be so soft as to permit compression of its lumen. The Westermarck catheter is 37 cm in length and made of silver, with an internal diameter of 3 mm and with the external end closed with a stopcock. Externally to the stopcock is a screw thread, which connects the catheter with the tube that leads to the manometer. The entire system is filled with water, which should contain no air bubbles. The author describes the conduction system that connects the uterine catheter with the manometer and the registration apparatus. He conducted tests with the apparatus. He reviews the cases and gives tabular reports of the results of the measurement, expressed in milligrams of mercury taken at five second intervals. At the beginning of the labor pain the pressure as thus recorded was usually around 20 mm of mercury. The maximal pressures varied greatly up to 168 mm of mercury. Westermarck also records the pressures during the intervals between pains and the duration of the pains. His observations indicated that the pressure of the labor pains increases as the process of delivery advances and reaches the maximum at the end of labor.

In the literature of recent years, new methods have been described for the graphic recording of the contractions of the parturient human uterus. Because the intra uterine methods of registration were complicated and not without danger of infection, external hystero-graphic methods were devised. Crodell (*Ztschr f Geburtsh u Gynak* 97/138, 1930) described a method of tocography. Crodell's method was employed also by E. Frey and Doris Wenner (*Arch f Gynak* 152/447 [Feb 27] 1933 abstr *THE JOURNAL*, May 20, 1933, p 1648). Frey (*Zentralbl f Gynak* 57/548 [March 11] 1933) devised a hysteronotograph and S. M. Dodek of Cleveland has described a method of external hystero-graphy (*Surg, Gynec & Obst* 55/45 [July] 1932).

Temesvary of Budapest introduced in 1932 a method of procotocography. He introduces a metreurynter into the rectum (*Zentralbl f Gynak* 56/130 [Jan 16] 1932, abstr *THE JOURNAL*, April 2, 1932, p 1235).

K. Podleschka of the German University in Prague has described a method of cystotocography (*Arch f Gynak* 152/159 1932). He registers the pressure of labor pains by measuring the pressure that becomes manifest in the urinary bladder. Following are some additional references to the subject.

#### USE OF COD LIVER OIL BY PROETZ DISPLACEMENT METHOD IN SINUSITIS

To the Editor—Please give me information on the value of the instillation of cod liver oil into the sphenoid and ethmoid sinuses by the Proetz displacement method for the treatment of a chronic sinus infection of very long standing. I have recently tried this method of treating my own sinusitis using Squibb cod and halibut liver oil. The improvement has been rather marked. Over the last four years almost every other method outside of operation has been tried without any apparent improvement. MD Pennsylvania

ANSWER—The use of cod liver oil in the treatment of sinusitis by any method is new, although other oils have been used with success. Apparently the action is merely one of lubrication, as liquid petrolatum serves as well as the other oils employed in these cases. Thus, Proetz says:

The effectiveness of lubricants in relieving sinus irritation and its attendant headaches was brought to my attention by Granger, who describes a case in which there was continuous headache day and night for four weeks, and which disappeared promptly and completely following an injection of lipiodol for diagnosis. Potts cites the case of a woman with a headache of several weeks duration who was similarly relieved. I have since encountered instances of this nature and attribute the relief to the lubricating properties of the lipiodol rather than to any intrinsic therapeutic action of this oil (which is inert, at least with respect to its iodine content), because like results have followed the administration of simple liquid petrolatum of low specific gravity. It is not unlikely that the headaches in these instances were due to the inspissation and possibly the contraction of the secretions in sensitive locations, or to the drying of the membrane itself through unequal ventilation, and that the oil relieved them by simple lubrication. One may employ the light liquid petrolatum referred to, or some simple oily solution, such as the familiar phenol-iodine petrolatum combination (phenol 0.06 Gm, iodine 0.01 Gm, petrolatum 100 Gm). The latter is especially helpful in ozena. The bland vegetable oils are equally effective, provided that there is no

individual sensitivity to them. They have the disadvantage of becoming rancid"—Proetz, A. W. *The Displacement Method of Sinus Diagnosis and Treatment*, St. Louis: Annals Publishing Company, 1931, p. 59.

#### BRITTLE FINGER NAILS

*To the Editor*—A well nourished spinster aged 50 complains of brittle finger nails which detract from the appearance of her hands. She is of a nervous temperament but does not bite her nails. Her home life is unpleasant as her parents are semi-invalids and somewhat tyrannical. She has servants and does not have to do any work that requires immersion of her hands in water. I noticed a beauty article which advised immersing the finger tips in warm olive or almond oil at night and also a high calcium diet. Is there any scientific backing for these measures or is there anything else that might be of help in this case? The patient appears to be in good health otherwise and has a negative history. Kindly omit name and address.  
M D Illinois

*ANSWER*—Brittle finger nails may be dependent on local causes that produce excessive dryness of the nail plate such as nail polishes, polish removers and strong soaps. The constitutional causes in otherwise healthy persons are obscure. As in any condition of the skin or appendages associated with dryness the application of bland oils is beneficial. The internal administration of calcium, with associated vitamin therapy (vitamins A and D) is also of benefit in cases resistant to local measures.

#### SENSITIVITY TO TETANUS ANTITOXIN

*To the Editor*—Does the administration under an ether anesthetic of tetanus antitoxin to a hypersensitive individual eliminate the danger of anaphylaxis and the necessity of desensitization? Please omit name and address.  
M D Maryland

*ANSWER*—In spontaneous sensitiveness to horse emanations and horse protein ether anesthesia could not be relied on to prevent acute anaphylactic shock following the injection of tetanus antitoxin. In sensitiveness due to previous injection of horse serum, ether anesthesia might appear to delay or mask to some extent the possible immediate reaction that might follow reinjection of horse serum.

#### NURSING BY SYPHILITIC MOTHER

*To the Editor*—Proper antisyphilitic treatment was begun in a pregnant woman with a 4 plus Wassermann reaction during her second month of pregnancy. A normal child was born. The blood Wassermann reaction of the child was negative at birth and at 1 month and 3 months. Can the mother breast feed the child without fear of infecting the child with syphilis through the milk? The mother of course is still under antisyphilitic treatment. Her blood Wassermann reaction is still 4 plus. Please do not publish name.  
M D New York

*ANSWER*—The mother may safely nurse the baby as long as she is under adequate treatment.

#### BELCHING

*To the Editor*—What is the best preparation to use for patients who complain of frequent belching of gas even after drinking water? Please omit name.  
M D Michigan

*ANSWER*—Patients complaining of frequent belching should be given the benefit of a thorough examination, including gastric analysis, gallbladder visualization and gastro intestinal investigation. If no organic disturbance is found a diet should be prescribed avoiding the highly seasoned greasy and fried foods and either alkaline powders or dilute hydrochloric acid may be given after meals. Occasionally patients are air swallowers and one must be careful to caution them against continuation of this habit.

#### PHOTOGRAPHIC CYSTOSCOPES

*To the Editor*—I am anxious to take some photographs of the inside of the urinary bladder. I have attempted unsuccessfully to use a Leica camera held close to the cystoscope. I will appreciate any information that you may have on this subject or suggestions where I can find it.  
M D Pennsylvania

*ANSWER*—There are many different makes of so called photographic cystoscopes. Any medical instrument house can supply information.

#### DERMOGRAPHISM

*To the Editor*—A man aged 23 has no abnormalities so far as I can find except marked dermographism. This is so noticeable that it is very embarrassing for him. Would you please advise a plan of treatment? Please omit name.  
M D Oregon

*ANSWER*—The treatment of dermographism is apt to be disappointing. The subject was discussed in *THE JOURNAL* Aug. 3, 1935, page 386.

#### APICAL ABSCESES OF TEETH

*To the Editor*—Under *Queries and Minor Notes* in *THE JOURNAL* January 4 a physician asks what should be done about several asymptomatic apical abscesses discovered by roentgenograms in an apparently healthy person. In your reply you question the proof of apical abscess based wholly on a radiolucent area about the apex of a tooth but you accept the term apical abscess which is commonly a misnomer as implying rarefaction of bone about a pulpless or devitalized tooth and is not usually an abscess in the accepted sense of the word.

Then you proceed to say what should be done after a correct diagnosis has been made by roentgenograms: direct observation and clinical history. Direct observation and clinical history often throw no light on the diagnosis of asymptomatic pulpless teeth. And all this seems of little import when our chief aim is to discover by roentgenograms the presence or absence of pulpless teeth, pyorrhea and other conditions apart. In questionable cases of pulpless teeth in which the pulp canal has not been filled the vitality should be tested by heat and cold and the electric current. Granted a correct diagnosis of a devitalized tooth what shall be done about it? Devitalized or pulpless teeth are almost invariably infected ultimately as shown by the innumerable and painstaking experiments of Rosenow and others and are always a menace to health. But you go on to state that a cure of pulpless teeth is possible without extraction and that the clinical and laboratory history in thousands of such cases have shown that such conditions [pulpless teeth] can be cured and the patients remain permanently well in more than 70 per cent of cases.

This taken literally is an untenable statement. How is it possible to know that such conditions are cured without extraction of the teeth and taking cultures of them after treatment? But the truly extraordinary assertion is that 70 per cent of thousands of persons remain permanently well by this treatment. Do any persons remain permanently well after any treatment whatever? It would pay adults to have their teeth devitalized if they could thereby achieve such a percentage of permanent health by this treatment. If there is any treatment (except extraction) by which a devitalized tooth may be restored to vitality it is as yet unknown. The failure to describe this marvelously successful form of cure of devitalized teeth is an inexplicable omission. The treatment presumably consists of either the resection of the apex of the pulpless tooth or the complete filling of the supposedly sterilized pulp canal. Neither of these methods prevents future infection of devitalized teeth as proved by the exhaustive researches of Rosenow and others since infection arises from the blood stream owing to the lowered resistance of the infected structures about the devitalized or pulpless tooth. Moreover the ablest clinicians have found by experience that devitalized teeth however skilfully treated not infrequently become a source of infection.

Three points I wish to stress: 1. The term apical abscess is usually incorrect. The condition so called is ordinarily (not always) not an abscess as affecting chronic asymptomatic pulpless teeth but roentgenologically refers to rarefaction of bone from infection of devitalized or pulpless teeth. 2. The degree of hazard to which the patient is subjected cannot be determined by roentgenograms. Thus so-called large apical abscesses particularly menacing to the roentgenologist may be less dangerous to health from old walled in infection than what may be taken as a normal roentgenogram of a completely filled devitalized tooth. 3. The treatment of devitalized teeth other than by extraction is fallacious and does not prevent future infection.

But it does not follow that pulpless or devitalized teeth should be extracted as soon as discovered. That is a matter that must be left to the experienced practitioner who understands that the presence of a pulpless tooth in the mouth is always a potential menace to the possessor.

This subject is of extreme importance as nearly 90 per cent of adults have pulpless teeth and the chief resource of the modern practitioner in a vast number of chronic disorders susceptible of alleviation is the removal of focal infections. Among these devitalized or pulpless teeth are probably the most important and frequent.

KENELM WINSLOW M D Seattle

#### APPLICATION OF X RAYS IN CANCER OF THE BREAST AND TO THE OVARIES

*To the Editor*—I read with some surprise in *THE JOURNAL* March 14 page 944 in *Queries and Minor Notes* the remarks under the heading of "Application of X Rays in Cancer of the Breast and to the Ovaries." In your answer to the letter asking for information you state that roentgen therapy to the ovaries has no place in cases of cancer of the breast. This would seem to me rather dogmatic. In 1896 Bert advocated removal of the ovaries as a palliative measure in the treatment of cancer of the breast. Several articles on the subject have appeared recently based on a more careful and scientific study of the relation of the ovaries to the breast. In December 1924 Taylor published a paper in the *New England Journal of Medicine* (221:1138) reviewing the literature. In his conclusions he states that radiation castration following radical operation may inhibit or postpone the development of metastasis. He gives a good bibliography. The subject is reviewed also in the *New England Journal of Medicine* in the December 1935 issue (213:1202).

In June 1935 Dresser presented a paper before the American Radium Society in which he reported the results of a series of cases of cancer of the breast treated by roentgen castration. The analysis suggests that the treatment was beneficial. This paper is to appear shortly in the *American Journal of Roentgenology and Radium Therapy*.

While much more investigative work is necessary before any authoritative statement can be made the evidence at present suggests a distinct relation between the ovarian hormones and cancer of the breast and that radiation castration in women before the menopause is a justifiable procedure. We are advocating it in the Tumor Clinic at the Massachusetts General Hospital and at the Collis P. Huntington Memorial Hospital (Cancer Hospital). It is advised also at the State Cancer Hospital at Portland.  
CHARLES C. SIMMONS M D Boston

## Book Notices

*The Human Foot Its Evolution Physiology and Functional Disorders* By Dudley I Morton Associate Professor of Anatomy College of Physicians and Surgeons Columbia University Cloth Price \$3 Pp 244 with 100 illustrations New York Columbia University Press 1935

The author traces the origin of vertebrate limbs from the protoplasmic primordial forms of organic life. The gradual development of the human foot is presented in an interesting and authoritative manner. The physiology of the foot and the mechanics of weight bearing and locomotion are well described and analyzed. The author states that the great majority of common types of "arch trouble" are caused by accumulative traumatism resulting from uneven weight distribution and faulty movement of stresses through the foot. This gives the average reader something to think about.

By means of two ingenious mechanical devices, the staticometer and the kinetograph, the author shows that the body weight is borne equally on the four lateral metatarsal heads and that the first metatarsal head bears twice as much weight as any one of the lateral heads. He concludes therefore, that there is actually no anterior transverse metatarsal arch. This corroborates the opinion of some other writers and is probably correct. He emphasizes the importance of "hypermobility of the first metatarsal segment," which means the existence of an unusual amount of motion between the medial and the middle cuneiform bones. He believes that this is demonstrated in x-ray films in certain cases. This hypermobility predisposes the individual to abnormal stresses. An unusual shortness of the first metatarsal bone is another element of importance contributing to abnormal stress in weight bearing in that it places too much strain on the second metatarsal bone as evidenced by a definite hypertrophy of the shaft of the second metatarsal. This hypertrophy is well shown in the accompanying roentgenograms, although it does not prove the correctness of the deduction.

Shortening of the gastrocnemius and soleus is an important factor in foot disorders and may be either congenital or acquired. High heeled shoes and prolonged recumbency during illness without proper prevention of foot drop, are mentioned as contributing causes. The x-rays are of great importance in the examination of the feet and are too often neglected. The most common reason for the functional disorders among women is the temptation to use the more abusive type of shoes. T G Morton's metatarsalgia is not due to the pinching of nerves but to traumatic arthritis with effusion of the second tarsometatarsal joint in association with congestion and irritability of the median plantar nerve. The effusion permits a certain amount of abnormal movement between the bones. When these movements occur, a stabbing pain is referred along the nerve. Some orthopedic surgeons might hesitate to accept this explanation in view of the fact that attacks of Morton's metatarsalgia

occur only while the patients are wearing shoes. When walking without shoes no pain is felt. "The symptoms of painful or clinical, disorder are directly traceable to traumatic cellulitis involving the nerves." This statement, while possibly correct, has not been substantiated by pathologic demonstration, so far as the reviewer is aware.

The book is not a compendium of the disorders of the foot and their treatment. The author has spared his readers any discussion of 'athletes foot'. He advocates no new and original operation for bunions. He shows diagrams of only two simple and practical devices to correct improper weight bearing and thus earns the reader's undying gratitude. He has on the other hand, presented in a clear and logical manner the conclusions reached through an enormous amount of research and experience. It is a fascinating and instructive volume.

**The Application of Absorption Spectra to the Study of Vitamins and Hormones.** By R. A. Norton D.Sc. Ph.D. F.R.C. Department of Chemistry, The University of Liverpool. Cloth. Price 10s. 4d. Pp. 70 with 31 illustrations. London: Adam Hilger Ltd. [n.d.]

In this little volume the author presents in an attractive manner the contributions of absorption spectrophotometry to the identification and isolation of vitamins and hormones with a scant mention of carcinogenic compounds. Vitamins A, B<sub>1</sub>, B<sub>2</sub>, C, D and E are treated in the space of fifty-eight pages only three pages being devoted to the hormones. Among the hormones mentioned are the follicular hormone corporin, thyroxine, insulin and epinephrine. It is pointed out that in the hormone field the scantiness of available data makes it impossible to predict how useful spectrophotometric methods may ultimately be because the chances for successful application are greatest for ring compounds possessing two or three double bonds and/or carbonyl groups. The value of the spectrophotometric data given by the author is enhanced considerably by the fact that they are presented in correlation with essential chemical and physiologic properties of the compounds in question. In this context the reader is made to feel that spectrophotometric methods constitute a most useful tool for the study of important biologic compounds while fully recognizing the fact, as pointed out by the author, that for the detection and identification of vitamins and hormones the animal constitutes the court of first and last resort. The publication of this volume is especially timely, as spectrophotometry in biologic research has been a neglected tool. Undoubtedly the scope of its use will be considerably widened by the information now made easily available.

**A Geography of Disease. A Preliminary Survey of the Incidence and Distribution of Tropical and Certain Other Diseases.** By Earl Baldwin McKelvey M.D. Dean and Professor of Bacteriology, School of Medicine, George Washington University. A study made possible by a grant from The American Leprosy Foundation (formerly The Leonard Wood Memorial) to the division of medical sciences of The National Research Council, Washington, D.C. Published as a supplement to The American Journal of Tropical Medicine. Cloth. Price \$5. Pp. 49. Washington, D.C.: George Washington University Press, 1935.

In 1929 it suddenly seemed imminent that a philanthropist in America might endow the subject of tropical medicine with a fund estimated at about \$40,000,000. reads the introduction. The provocative mirage faded but a book was born possibly a souvenir of what has been termed the 'whoopie era' of medical expansion. It represents a compilation of answers to voluminous questionnaires sent to innumerable health officers in various parts of the world. The project must have given employment to a considerable number of clerks and the compiled results may in addition prove useful to public health workers and investigators interested in tropical diseases. It is obviously handicapped by the limitations of the accuracy of the reports that form the basis of the work. Fifteen American states have been included in the morbidity survey, if the material from these is used as a criterion of the usefulness of the data from other countries that usefulness will probably not be great. It might have been advantageous to provide population statistics for the states selected because ready comparisons are difficult without them. For the foreign countries surveyed adequate information of this type has been supplied in the text. Throughout the effort has been made to provide morbidity statistics. It need not be pointed out that morbidity statistics

are misleading in the best regulated countries, in the less advanced regions of the world such tabulations are sheer guesswork. Nevertheless an investigator interested in the tropical diseases of the island of Mauritius, for instance, will immediately have available a 1934 report, from which he can observe that malaria, blackwater fever, dengue fever, leprosy, syphilis and with them amebic dysentery and typhoid, are prevalent and so too there is information concerning twenty-five other diseases that are commonly recorded as typically tropical. There are 116 tables of this type covering practically all countries of the world. Part 5 of the volume consists of short topical summaries contributed by a distinguished group of authors. In these bacillary dysentery is well presented (considering its uncertainty) and so is brucellosis and dengue fever. Indeed, in every instance an expert in the field of the particular disease has evaluated the results of the survey and has in succinct fashion presented suggestions for further study and research attack. Probably this portion of the book is really of greatest value.

**A Text Book of Medicine for Nurses.** By E. Noble Chamberlain M.D. M.Sc. M.R.C.P. Assistant Physician, Royal Infirmary, Liverpool. With a foreword by Miss E. M. Vusson C.B.E. R.R.C. Chairman, General Nursing Council for England and Wales. Second edition. Cloth. Price \$7. Pp. 444 with 46 illustrations. New York & London: Oxford University Press, 1935.

This edition has been prepared in order that important advances in medicine, especially in relation to the blood diseases and disorders of the urinary tract might be included. Sections have also been added which discuss such diseases as undulant fever and coronary thrombosis. The publication of a new British pharmacopoeia has also made it necessary for the authors to rewrite the material on therapeutics and to make adjustments in the doses of various drugs. Throughout the book the nursing aspects of treatment are given especial attention. Nurses as well as all others whose work requires some knowledge of medicine should find this work of value.

**Food for the Diabetic. What to Eat and How to Calculate It with Common Household Measures.** By Mary Pascoe Huddleson. With an introduction by William S. McCann, Dewey Professor of Medicine, University of Rochester School of Medicine and Dentistry. Third edition. Cloth. Price \$1.50. Pp. 110 with 2 illustrations. New York: Macmillan Company, 1934.

Mrs. Huddleson's experience as a dietitian and editor of the *Journal of the American Dietetic Association* is reflected in the simple method she uses for teaching. The program given at the beginning of the text outlines a definite schedule, which is the foundation of all diabetic treatment. The importance of the protective foods is emphasized and the diet planned for the child includes four glasses of milk each day. It is refreshing to read the statement 'There is little danger of going over the carbohydrate allowance with the use of 5 per cent and 10 per cent vegetables even when these are roughly measured. Complete food tables for use in planning a diabetic diet and a few simple recipes are given. The chapter on the testing of urine for sugar and the explanation of insulin its action and proper administration is given in a detailed and definite manner and should prove to be of special value.

**Post Mortems and Morbid Anatomy.** By Theodore Shennan M.D. F.R.C.S. Professor of Pathology in the University of Aberdeen. Third edition. Cloth. Price \$9. Pp. 716 with 241 illustrations. Baltimore: William Wood & Company, 1935.

This book is essentially a postmortem manual and as such should be of value to younger pathologists, particularly if they are doing medicolegal work. Details of necropsy techniques are carefully described. The principal objections to the book are the price and the poor quality of binding (the reviewer's copy needed rebinding when received). The illustrations are good but are similar to those in regular textbooks of pathology and offer no educational advantages to a pathologist competent to perform necropsies. One wonders whether they do not add unnecessarily to the cost. The purposes of the book are praiseworthy and the author is to be commended but the manual can in no way replace a good textbook of pathology and therefore should be marketed in the price range of other dissection manuals.

## Miscellany

### THE HALL OF MEDICAL SCIENCE AT THE SAN DIEGO EXPOSITION

The Hall of Medical Science is one of the most striking attractions of the California Pacific International Exposition, at San Diego. This building, situated on the main Plaza de Pacifico is one of the finest and most advantageously located buildings in the exposition. The entire building is devoted to educational exhibits, showing the progress of modern medicine. The California Medical Association in cooperation with the San Diego County Medical Society, has had complete charge of the project from the finishing and furnishing of the building to the selection, installation and censoring of all exhibits. This

The progress of modern surgery is told by an operating suite, showing the surgery of 1882 in contrast with the surgery of an approved hospital of today. The operating rooms are complete in every detail, with a surgical staff presented in full sized figures.

An exhibit on maternal welfare by the Pacific Coast Society of Obstetrics and Gynecology is combined with one of the finest exhibits of graded embryos in America, lent by the Department of Embryology of the College of Medical Evangelists. Unique in this group are perfect specimens measuring 3 and 4 mm and a pair of 3 cm twins with all membranes intact. The exhibit of the Los Angeles Maternity Service presents three miniature homes showing all the arrangements for delivery and care of the baby in the home. The exhibit tells the story of the care of 21,000 charity patients delivered at home with a maternal mortality of only fourteen patients and also methods of reducing maternal mortality.

is probably the first time that an exposition has devoted all of one of its principal buildings to medical science and given the medical profession a free hand in the development of the exhibits. The exposition has financed the entire expense of the building.

The central and most important feature in the Hall of Medical Science is the exhibit of the American Medical Association covering about 1,400 square feet. The exhibit features public health problems, periodic examinations and the danger of self diagnosis. A constant projector gives the answers to the most frequent medical questions asked by the public. The display of the activities and publications of the American Medical Association with its constantly moving figures and brilliant changing illumination has a unique and intense popular appeal.

The California Medical Association has an equally large exhibit of public health subjects telling the story of tuberculosis, appendicitis, heart disease, vaccination, diet and medical education.

The care of the crippled child is demonstrated by exhibits lent by the Los Angeles Orthopedic Foundation, Los Angeles Children's Hospital and San Diego Society for Crippled Children.

An extensive exhibit on human pathology has been assembled from Pasadena Hospital, the College of Medical Evangelists, Los Angeles County Hospital, Stanford University Medical School and University of Southern California Medical School.

The San Diego County Health Department has prepared an exhibit on bacteriology, showing transparencies of photomicrographs of common pathogenic organisms, also growing cultures of bacteria and demonstrating methods of identifying bacteria.

The California Medical Association is sponsoring exhibits of plastic and reconstructive surgery and also exhibits of bronchoscopy and allergy.

Additional exhibits have been placed by the California Tuberculosis Association, the American Society for Control of Cancer, the Los Angeles Board of Health, the Department of Public

Health of California, the California State Board of Medical Examiners, the California Dairy Council, the Automobile Club of South California, the General Electric X-Ray Corporation, the Chicago Roentgen Society and Pacific Roentgen Club, the Stanford University Medical School, the University of Southern California College of Dental Surgery, the E H Angler Society for Orthodontia and the Pacific Coast Society for Orthodontists

The Hall of Medical Science has a large auditorium which will be devoted to presentations of moving pictures of public health and medical subjects and to scientific lectures throughout the exposition

The members of the Woman's Auxiliary of the San Diego County Medical Society has taken over the important task of acting as hostesses in the Hall of Medical Science. They preside over a large and attractive lounge, where visiting physicians and their families will be welcomed and where they may make their headquarters while visiting in San Diego

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Workmen's Compensation Acts Pneumonia Attributed to Facial Infection**—The workman, in the course of his employment, got a splinter in his cheek, which became infected. Cellulitis developed and hospitalization was necessitated. While at the hospital, the workman had pneumonia. He thereafter sought compensation for wage loss by reason of the pneumonia attributing that disease to the infection caused by the splinter. The industrial commission awarded compensation finding that "in view of the nature of the infection, and the sequence and continuity of events, the preponderance of probabilities point to the development of pneumonia because of the bacteria resulting from the facial infection having gained entrance into the blood stream and localized in the lungs". The circuit court affirmed the award and the employer appealed to the Supreme Court of Wisconsin.

Two medical witnesses testified for the workman. One testified that infections of the face have a tendency to get into the blood stream more easily than those of the hand or arm, and that he believed that there was an infection of the blood stream. He consequently thought there was a close association between the infection and the pneumonia. The other witness stated that the facial infection was a streptococcal infection and that pneumonia may result both directly and indirectly from an infection—directly from blood stream transmission and indirectly by a lowering of the patient's general resistance. He admitted that the connection between the facial infection and the pneumonia in the instant case could not be proved. He testified that it was possible that there was an infection in the blood stream although there was no demonstrable evidence of that infection, two blood tests having been found negative. On this evidence said the Supreme Court, there was not only no preponderance of probabilities of development of pneumonia because of bacteria resulting from the facial infection entering the blood stream but there was no probability at all. There was nothing more than a possibility and the industrial commission was not base awards on possibilities. There must be at least some proof of every essential fact to support an award. The award in the present case the court said was based on the inferred fact that the facial infection entered the blood stream and there was absolutely no evidence that it so entered. So far as the award was based on the pneumonia therefore the court held that it must be set aside but since the workman suffered some wage loss from the facial infection the case was remanded so that the industrial commission might determine what compensation should be allowed based on the facial infection alone—*Mayer & Co v Industrial Commission* (115) 263 N W 88

**Workmen's Compensation Acts Death from Sunstroke**—Death from exposure to the elements, including the heat of the summer and the cold of the winter said the Supreme Court of Iowa, is not compensable if the hazard is the same to which the general public is exposed. For compensation to be recoverable for death from sunstroke, the deceased must have been subjected to a greater hazard from heat than that to which the public generally in that locality was subjected. This distinction is recognized by all the authorities. Compensation was denied in this case—*Wai v Des Moines Asphalt Paving Corporation* (107) 263 N W 333

**Compensation of Physicians Liability of Third Person for Medical Services**—The plaintiff, a physician, sued the defendant to obtain payment for medical services rendered a Negro employee of the defendant. The Negro, suffering from a gun-shot wound, was taken to a hospital owned and operated by the plaintiff. Immediately thereafter the defendant came to the hospital and, according to the plaintiff, said "If you will go ahead and take care of the case, I will pay the bill". The testimony of several witnesses tended to corroborate the plaintiff. The defendant, however, denied that he had made the promise just noted and, from a judgment for the plaintiff, he appealed to the Supreme Court of Oklahoma.

The Supreme Court, however, believed that the evidence reasonably tended to support the verdict of the jury. In *May v Roberts* 28 Okla 619 115 P 771, relied on by the court in the present case the plaintiff, a physician, brought suit for services rendered the wife of the defendant's tenant. The defendant had requested the physician to visit the tenant's wife and told him that he would see that the bill was paid. Such evidence was held to be competent and material and to establish a primary liability not within the statute of frauds. Finding no error in the record in the present case, the Supreme Court affirmed the judgment in favor of the physician—*Gloccles v Weeden* (Olla) 50 P (2d) 634

**Optometry Corporate Practice of Optometry Illegal in Arizona, Injunction to Restrain Practice**—The Funk Jewelry Company, a corporation, employed a licensed optometrist to examine eyes and to prescribe glasses. The state of Arizona on the relation of the attorney general instituted action to enjoin the corporation from practicing optometry. From an adverse judgment in the trial court, the corporation appealed to the Supreme Court of Arizona.

The optometry practice act said the court, prescribes certain qualifications to be possessed by applicants for licenses to practice optometry. These qualifications necessarily exclude a corporation from practice. It cannot qualify. It does not possess the necessary moral and intellectual qualities. The corporation therefore when it employed a registered optometrist as a part of its business to examine eyes and to prescribe glasses, violated the optometry act. It was apparently contended however that even though the corporate practice of optometry was illegal, an injunction would not lie to restrain that practice. The optometry act observed the court prescribes no punishment for those who violate its provisions. Consequently the ordinary criminal sanctions such as fine and imprisonment are not available to prevent continued violations of the act. Unless the writ of injunction is available there is available no remedy to enforce the act. Furthermore the court continued while the civil process of injunction may not ordinarily be used to prohibit persons from committing a crime where the crime is a public nuisance or affects the interests of the state, injunctions will lie. *State v Smith* (Ariz) 29 P (2d) 718 31 P (2d) 102 92 A L R 168. The tendency is to grant injunctions to prevent unlicensed persons from practicing the professions. If the present action said the court had been brought by the state board of optometry or by members of the optometry profession, there would be no question of their right to maintain the action in view of the trend of judicial opinion. The present action, however was brought by the state, on the relation of the attorney general. The optometry act, continued the court, was

passed for the general welfare of the people of the state. Its purpose is to protect the health of the people, and, while the state may not have any pecuniary interest in the enforcement of the act, it has a very much higher interest, and that is in the protection of the health and well being of its people. That being the case, it seemed to the court that the state, acting through the attorney general, could lawfully apply to the courts to exercise their equity powers to enjoin violations of the act.

The corporation apparently further contended that the state board of optometry had entered into some kind of an agreement with the licensed optometrist whereby the board agreed that the optometrist might render the services for which he was employed for a limited length of time. Such an agreement, the court said, would not have the effect of suspending the requirements of the optometry act. Furthermore the agreement did not purport to authorize the corporation to practice optometry, and if it had the agreement would have been void.

The judgment of the trial court granting the injunction, was therefore affirmed—*Funk Jewelry Co v State ex rel La Prade (Ariz)*, 50 P (2d) 945

**Malpractice Ankylosis of Wrist Following Treatment of Infection**—A nurse, while attending a child afflicted with streptococcal infection of the throat Nov. 5 1930 pricked the thumb on her right hand deeply with a pin. Infection of the thumb developed and the defendant a physician was consulted. The nurse was removed to a hospital and the hand placed in a hot saline solution to localize the infection and hot wet compresses were applied. Later incisions were made and gradual subsidence of swelling and a lowering of the temperature resulted. On November 22 and 23 however, the nurse's hand gave evidence of ankylosis and the defendant applied a banjo splint to put the hand in a position of functioning. A cast was applied around the splint and the forearm. Claiming that a resulting stiffness of her fingers and wrist was due to the defendant's negligent treatment, the nurse brought suit against him. The trial court gave a judgment for the plaintiff and the defendant appealed to the Supreme Court.

There was a conflict in the evidence, said the Supreme Court, as to whether in the application of the banjo splint the defendant retroflected the hand at an angle of about 90 degrees or at an angle or from 40 to 45 degrees. The plaintiff contended that the defendant had applied to the hand a splint holding the hand in an exaggerated reflexed position, the hand being drawn back at an angle of about 90 degrees, and that the cast was applied around the splint and the forearm so tightly that it interfered with the circulation and with proper drainage. The defendant and the physician who administered the anesthetic prior to the application of the splint testified that the hand was placed in the splint at an angle of from 40 to 45 degrees. Without passing on the evidence, the Supreme Court was compelled to reverse the judgment of the trial court because of the court's refusal to instruct the jury as follows:

If under the evidence and these instructions you should find in favor of the plaintiff you can only allow her damages for so much of her disability as you believe from the evidence is due solely to the negligence of the defendant and not for any disability that you may find was due to the infection.

Under the circumstances of the present case, said the court, since the defendant was not responsible or liable for the original injury, but liable only, if at all, for subsequent negligent treatment, those phases should have been carefully separated by instructions in order that the jury might not be allowed to award damages on mere speculation and conjecture.

The hospital record continued the court, kept in the ordinary course of business was admissible in evidence as an exception to the hearsay rule where the particular entry in question was identified as having been made by a nurse who worked at the hospital and who attended the plaintiff although the nurse had subsequently left the hospital and her present whereabouts could not be accounted for. An instruction given by the trial court that the jury was not bound by the testimony of expert witnesses was not violative of a constitutional prohibition against judges commenting on the evidence.

For the error committed the judgment of the trial court was reversed and the cause remanded for a new trial—*Murgatroyd v Dudley (Wash)* 50 P (2d) 1025

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

Inflammatory Exophthalmos in Cranial Disorders of Accessory Sinus. M Cohen New York —p 457  
Minute Structure of Retina in Monkeys and in Apes. S Polak Chicago —p 477

**Exophthalmos in Catarrhal Disorders of Sinuses**—Cohen states that in inflammatory exophthalmos the venous circulation plays the important part. The veins being valveless permit infection to be carried to and from the orbit. The lesions in the orbit depend on the severity of the sinus infection. During the last three years 1517 patients with sinusitis have been treated in the wards of the Manhattan Eye Ear and Throat Hospital. In twenty-two cases the condition was complicated by inflammatory exophthalmos. There were two deaths, one from meningitis and the other from septic thrombosis of the cavernous sinus. Among the twenty-two patients with inflammatory exophthalmos there were eleven with acute ethmoiditis who were treated with medication to the eye and the nasal cavity. The remaining eleven patients were treated by conservative surgery, five by incision and drainage for subperiosteal or orbital abscess, four by external ethmoidectomy with opening of the sphenoid and two by surgical treatment of the frontal and ethmoid sinuses. The ocular signs of inflammatory exophthalmos are self-evident except in the mild acute cases in which the condition is caused by an inflammatory edema of the retrobulbar tissue. In this condition the exophthalmos, the ocular inflammation and the nasal condition are mild and respond rapidly to appropriate treatment. The patient recovers in a few days. The ocular and nasal signs in the more acute and subacute types are more marked and distinctive and are discussed with an illustrative report of a case. Cases of empyema of any of the sinuses with rupture into the orbit are recognized by a local swelling with fluctuation over the area involved which is accompanied by general symptoms such as pain, headache and increased temperature. Rhinologic and roentgen examination give positive evidence in addition to swollen nasal mucosa and discharge. The acute symptoms in this type persist for

about three or four weeks, after which the ocular signs gradually disappear. In the chronic type the symptoms are similar to those observed in the subacute type, but they are prolonged over a period of eight months or longer. The exophthalmometer is an aid in diagnosing doubtful cases of exophthalmos, this instrument also assists in judging the results of treatment. The treatment in these cases is concerned not only with the ocular condition but also with the sinus disease which is its primary cause. The prognosis is generally favorable in all types of cases, especially if the ocular and general symptoms are not progressive.

Clinical Study of Control of Bladder by Central Nervous System. O R Langworthy, L G Lewis, J E Dees and F H Hesser Baltimore —p 89  
\*Diagnosis of Obscure Fever. I. Diagnosis of Unexplained Long Continued Low Grade Fever. L Hamman and C W Wainwright Baltimore —p 109

**Diagnosis of Obscure Fever**—Hamman and Wainwright divide cases of obscure fever into two groups. The first group comprises cases with low grade fever, the temperature only occasionally exceeding 100 F and rarely reaching 101 F. The symptoms are not severe and the patients are usually ambulant. The second group comprises cases with higher fever and symptoms that are usually incapacitating. The patients as a rule are confined to bed. Without being able to determine accurately the cause of the fever in any specific case, one may conclude that it must have been due to (1) some mild specific infection, tuberculosis, Malta fever, rheumatism, (2) some focus of septic infection, tonsillitis, appendicitis, pyelitis or uncertain causes about which instruction is meager, metabolic disorders, neurogenic fever. Of the uncertain causes it may be said that there can be little doubt that hysterical manifestations may be accompanied by fever. In psychotic patients, whether agitated or depressed a little fever is almost regularly observed in spite of the fact that careful examination reveals no cause for its occurrence other than the abnormal mental state. Psychiatrists have often commented on variations in the temperature of psychoneurotic patients regularly recurring in relation to psychiatric treatment and mental trauma. That obscure clinical condition called effort syndrome, exhaustion syndrome, disordered action of the heart or neurocirculatory asthenia is nearly always accompanied by slight fever. Finally, some few persons may have a thermoregulatory mechanism set at a high level and for them a temperature between 99 and 100 F may be normal. Even though the physician may be convinced that such anomalies do sometimes occur he is never justified in making this diagnosis under any concrete circumstances.

- Maggot and Allantoin Therapy in Tuberculous and Nontuberculous Suppurative Lesions of Lung and Pleura Report of Eight Cases N Bethune Montreal—p 322

**Pleuropulmonary Complications of Amebiasis**—Ochsner and DeBakey state that pleuropulmonary complications of amebiasis occurred in 158 per cent of 2490 reported and in 157 per cent of their ninety-five consecutive cases of amebic hepatic abscess. Men are involved much more frequently than women. Such complications occur as a rule from an extension of amebic hepatic abscess. Perforation of the abscess occurs rarely into the free pleural space but more frequently into the lung or bronchus. Exceptionally hematogenic pulmonary amebic abscesses may occur. Pleuropulmonary amebic infections are classified into five groups, depending on the type of pleuropulmonary involvement: (1) hematogenic pulmonary abscess without liver involvement; (2) hematogenic pulmonary abscess and independent liver abscess; (3) pulmonary abscess extending from liver abscess; (4) bronchohepatic fistula with little pulmonary involvement; and (5) empyema extending from liver abscess. The clinical manifestations of pleuropulmonary amebiasis consist chiefly of cough and expectoration, fever, diarrhea, enlarged and tender liver, pain in the chest and cachexia. Cough and expectoration were observed in 92.5 per cent of the collected cases, fever in 43.2 per cent, a history of a previous diarrhea was obtained in 41 per cent, an enlarged liver present in 39.7 per cent, diarrhea at the time of admission in 33.5 per cent, and pain in the chest in 31.3 per cent. The expectoration of chocolate sauce pus is indicative of a communication between a liver abscess and a bronchus and is of diagnostic importance. Pulmonary manifestations consist of consolidation and cavitation. There is a moderate leukocytosis without concomitant increase in the polymorphonuclear leukocytes; marked leukocytosis is indicative of a secondary infection. Roentgen examination shows elevation and fixation of the diaphragm and a shadow at the right base particularly in those cases in which a pulmonary abscess extends from a liver abscess. The shadow is triangular with the base below and the apex above. Diagnosis can be established by the charac-

teristic chocolate sauce pus and the finding of amebas in the sputum and aspirated material. The prognosis in pleuropulmonary amebiasis is dependent on the type of the lesion and the therapy employed. The mortality rate in the collected series was extremely high (41.1 per cent). The treatment of pleuropulmonary amebiasis consists of the administration of emetine and the aspiration of those abscesses not sufficiently evacuated through the bronchus. Open drainage should never be done except in cases in which there is secondary infection. The incidence of recovery in cases treated without emetine in the collected cases was 43.9 per cent and in the authors' cases 40 per cent, whereas in cases in which emetine was administered the respective incidences were 91.8 and 100 per cent.

**Surgical Revision of Unsatisfactory Thoracoplasty**—Kinsella obtained improved results in a number of patients who were subjected to reoperation whose thoracoplasties have proved unsatisfactory. When combined with some form of extrapleural (subscapular) packing the results have apparently been more certain, although the procedure is somewhat more formidable. The results to date justify a more extensive use of this procedure. The application of some type of subscapular pressure at the time of primary operation would seem advisable in certain selected cases and may obviate the necessity for reoperation later.

**Roentgen Study of Encapsulated Interlobar Effusions**—Rigler presents roentgen observations of cases of pleural effusion, of cases of pneumonia and one detailed report of a case in which there was an encapsulated interlobar empyema in order to demonstrate that: 1 Free pleural effusions may extend into the interlobar fissures, particularly in the horizontal positions; 2 Roentgenologically these extensions may simulate encapsulations; 3 Encysted interlobar effusions may develop as a result of such an extension if adhesions form during the course of the effusion; 4 This may be the common mechanism for the development of the interlobar encapsulations which complicate pneumonia.

**Treatment of Acute Colds with Bacteriophage**—In 1933 Schreuder gave bacteriophage-lysed bacterial antigen subcutaneously in dosages of 0.4, 0.7 and 1 cc on three successive days to 169 patients with symptoms limited to the nose and upper part of the pharynx who had the cold less than forty-eight hours. Sixty-six patients were definitely improved, sixty-five were slightly benefited and thirty-eight experienced no relief. In view of these results it was decided to treat the common infections of the respiratory tract in the winter of 1934-1935 by the same means and to run a control by giving inoculations with sterile physiologic solution of sodium chloride.

No other treatment was given except general advice as before. Of twenty-nine cases treated by injections of bacteriophage-lysed bacterial antigen ten were definitely benefited, nine slightly benefited and ten unimproved. Of the thirty-one patients given injections of physiologic solution of sodium chloride sixteen were definitely relieved, ten experienced slight benefit and five had no relief. The conclusion is that subcutaneous injections of bacteriophage-lysed bacterial antigen is of no benefit in the treatment of acute colds.

Traumatic Cerebral Edema in a Child of Six Months with Associated Skull Fracture F. L. Wilson and R. I. Gorrell Stuart—p. 95  
Diagnosis and Treatment of Anemia III Pernicious Anemia J. C. Sharpe Omaha—p. 98

**Diagnosis and Treatment of the Psychoneurotic Patient**—Bennett and Semrad found that seventy-two of 100 psychoneurotic patients were admitted with erroneous diagnoses of some severe organic disease. In twenty-nine instances serious organic gastro-intestinal disease was diagnosed yet did not exist. In fourteen cases endocrine diagnoses were made usually of toxic hyperthyroidism when anxiety hysteria was the disabling disorder. Fifteen patients were admitted as suffering from serious organic cerebral disease. Other diagnoses of serious organic trouble referable to almost all the bodily systems were made erroneously. These mistakes in diagnosis come largely from lack of a general understanding of the principles of psychopathology, failure to elicit an adequate history and to consider situational and psychogenic factors, and failure to appreciate the importance of the personality makeup of the patient. In evaluating symptoms many physicians overlook the emotional setting out of which the physical sensations develop in the neurotic patient. Ill advised therapeutic procedures were very common in the group, 179 surgical operations had been performed on seventy-three patients, at least half of which were probably unnecessary. Adequate psychogenic and personality factors to account for the etiology were found in all cases. At least half of the patients had marital domestic or sex conflicts. Hypersensitive and introverted constitutional traits were frequent. Economic conflicts and hereditary factors accounted for the remainder. After psychotherapeutic procedures 70 per cent of the patients were definitely improved. More adequate training in the principles of psychobiology and psychopathology are necessary for the general physician to understand the psychoneurotic patient. Psychotherapy is the logical approach and offers the only scientific method of relief for this large group of maladjusted personalities.

Inversion of Uterus in Two Consecutive Pregnancies Case Report R. E. Stewart Boston—p. 373

**Hutchinson-Boeck's Disease**—The evidence from previously reported cases and from the case cited by Hunter is that Hutchinson Boeck's sarcoid is a systemic disease. It affects at times not only the skin but the lymph glands—both peripheral and those at the hilus of the lungs—the spleen, the parenchyma of the lungs, the phalanges of the fingers and toes, the mucous membranes, the conjunctivae and the parotid gland. In its power of invading many organs it simulates lympho-

blastoma. Iritis is not infrequently a precursor or accompanies the skin lesions. One of the probable reasons why it has been overlooked so long by the internist is the multiple and formidable nomenclature given it by dermatologists and others. The case presented showed changes limited to the skin and reticulo endothelial system—lymph nodes and spleen, for, although Kismeyer doubts the involvement of the spleen in many of the reported cases, the fact that under treatment this patient showed a decrease of the splenic enlargement which paralleled the regression of the lymphadenopathy cannot, in the author's judgment, be dismissed as fortuitous. It seems logical, therefore to assume that the spleen would have shown the same morbid histology as that demonstrated in the biopsy of a lymph node, typically sarcoid. This malady offers a possible solution to another problem, that of the true diagnosis in instances in which apparently healthy patients without skin lesions, give evidence of increased hilus shadows accompanied by diffuse infiltration of the lungs at roentgen examination, an appearance not infrequently reported by roentgenologists as tuberculosis. More careful roentgen and clinical observation may in the future determine whether these patients are suffering from Hutchinson-Boeck's "sarcoid."

Addison's Disease Report of Case J. M. Coppoletta Cliffside Park and W. J. Monaghan Laurel Hill—p. 90

**Endocrinology and Convulsive Conditions**—Pigott is of the opinion that in a certain proportion of convulsive conditions there is a possible relationship between some endocrinopathy and the convulsions. There are too many epileptic patients coming into institutions showing gross evidence of dysfunction of the glands of internal secretion to disregard them entirely as an etiologic or a concomitant factor, and the fact that substitution therapy has failed to relieve the attacks in most of these cases is not sufficient evidence for one to ignore the endocrines, but rather a reflection on one's ability to determine which gland or glands are at fault and the inadequacy of the preparations used in the treatment. However, the author hesitates to make a positive claim to a specific connection between the endocrines and convulsions, especially epileptic convulsions, and he bases his deductions almost entirely on clinical observation with little or no experimental data to substantiate them. He discusses each of the endocrine glands separately. In addition to a consideration of each of the endocrines as a separate unit, there are numerous interrelationships that probably play a part in the production of convulsive seizures, and, as Turner has pointed out, the rather frequent occurrence of physiologic and morbid changes in the endocrines in cases of epilepsy gives an indication of the relationship of these glands to this condition and one is readily able to suppose that convulsive crises may be lessened by a normal physiologic balance and aggravated by an abnormal balance.

Investigations into Urea Nitrogen Content of Blood Following Anesthesia Eileen A. Boyd introduction by R. Jarman—p. 56  
Combined Evipan-Novocain Anesthesia G. Bankoff—p. 66

**Anesthesia**—Sykes points out that it is possible to reduce postoperative mortality below the 4 to 5 per cent average. Certain minimal essentials are required to create a satisfactory service: 1. Resident anesthetists should be appointed at all large hospitals without exception. 2. No person should be appointed as visiting anesthetist without previous experience as resident, thus bringing anesthesia into line with all other branches of medicine and surgery. 3. Anesthetic clerkships should be compulsory for the better instruction of students. 4. It should be an absolute rule that no dresser be allowed to give an anesthetic except under direct supervision. 5. Patients in private wards should invariably get what they pay for—the personal care of an experienced anesthetist. Under no circumstances should the same fee be payable to a senior member of the staff and to a newly qualified house surgeon. 6. The equipment of many hospitals requires a drastic overhauling. Good modern gas machines should always be available. 7. These machines, though robust, are not fool proof. Therefore, no one except people familiar with their construction and mechanism should be allowed to use them or they will never be in working order, nor will satisfactory anesthesia be obtained. Financial considerations in the form of repair bills may thus do what the interests of the patient have failed to do, that is, protect patients against the dangers of unskilled and unsupervised anesthesia. 8. As the science of anesthesia is constantly changing and constantly advancing in common with the rest of medicine and surgery, provision should be made so that suggestions for reforms and improvements may be brought to the notice of the governing body without loss of time.

Resurvey of Hookworm Disease in Fiji in 1935: Ten Years After Mass Treatment S. M. Lambert—p. 19

**Yeastlike Fungi in Sputums of Tuberculous Patients**—Ying examined the sputums of 100 patients with pulmonary tuberculosis and twenty normal subjects. The patients are instructed to brush their teeth and to wash their oral cavities with Dobell's solution. A few minutes afterward the sputums expectorated are collected in different sterilized receptacles and are immediately washed with 70 per cent alcohol for five minutes and with physiologic solution of sodium chloride for a few minutes and then cultured on Sabouraud's medium and 8 per cent dextrose agar respectively. Of the 100 specimens nine showed positive cultures and in the twenty healthy individuals there was one positive culture. In the positive cultures tiny cream colonies were noticed on the second to the fourth day. The author classifies the ten yeastlike organisms on the bases both of morphology and of their biochemical characteristics. Basing the classification on the morphologic characteristics according to Langeron he classifies his strains as *Candida Mycocandida*, *Mycotorula* and *Mycotoruloid*. Basing the classification on their biochemical characteristics after Castellani, they are classified as *Monilia bronchitica* Castellani, *Monilia pinovi* Castellani, *Monilia krusei* Castellani, *Monilia tropicalis*

Castellani and *Monilia (cryptococcus) macroglossiae* Castellani. Animal inoculation shows that these monilias obtained from the sputums of the tuberculous patients are more pathogenic. From his study the author is of the opinion that the presence of yeast like fungi in the lung is possible without giving rise to symptoms or signs. Or it may be that these symptoms are so slight that they do not attract the attention of the patient, and at the same time the signs are so slight that they cannot be detected clinically.

## Medical Journal of Australia, Sydney

- Surgical Sequels of Acute Cerebral Trauma G. Phillips—p. 41  
Sequels of Head Injuries C. G. McDonald—p. 45  
\*Acute Upper Abdominal Pain J. C. Storey—p. 52

**Acute Upper Abdominal Pain**—Storey divides true abdominal pain of the upper part of the abdomen into three classes: (1) the colic due to the spasmodic contraction of a hollow viscus or duct during its attempt to expel anything acting as an obstruction, (2) the continuous pain of tension in similar organs and (3) pain due to irritation of the peritoneum. The worst pain of the upper part of the abdomen is probably associated with acute hemorrhagic pancreatitis, and no less unbearable is that of perforation of a duodenal ulcer. Gallstone colic can be almost as bad. When one is called to a patient who is overwhelmed with pain in the upper part of the abdomen, action should be prompt, for delay may mean death. The signs, symptoms and treatment of gallstone colic, cholecystitis, acute pancreatitis and perforation of duodenal ulcer are heralded by pain in the upper part of the abdomen are discussed. A leaking or ruptured hydatid cyst must be considered in all patients with acute pain of the upper part of the abdomen. Coronary thrombosis is a fashionable diagnosis, and while it is bad enough to mistake this condition for a perforation, the reverse error is worse. Spasm of the celiac vessels can be mistaken for a surgical emergency. The author has seen a patient with tetanus admitted to the hospital with a diagnosis of an abdominal crisis. Renal colic is sometimes projected forward, but as a rule no confusion need arise. Perforation of a gastric carcinoma is rare, as is the bursting of the gallbladder. Malaria may mimic any disease. Acute appendicitis is the most common cause by far of all abdominal emergencies, and the initial pain is often high, so that it may be difficult to exclude the old favorite.

Postclimacteric Hemorrhages and Their Relation to Malignant Neoplasms W Wittenbourg and A Zlatmann—p 1026  
Urinary Tract Diseases as Indication for Sterilization of Women B Zlatmann—p 1054

**Menstrual Disorders Treated by Roentgen Rays**—Wittenbourg and Porthovnik report observations on 117 young women with functional menstrual disturbances treated by roentgen rays. All seemed to be connected with the ovarian function but presented considerable variation in symptoms. Sometimes the difficulty was in the length of the cycle sometimes hypomenstruation or hypermenstruation, and sometimes a combination of the two. The cyclic disorders or their combination with hypomenstruation respond best to roentgen therapy. Amenorrheas are more refractory. The prognosis as to complete cure is less favorable when the patient is older. It becomes especially uncertain when the patients presenting amenorrhea are more than 30 years of age. The more hypoplastic the uterus, the less is the chance for a good effect. In some cases (about 15 or 18 per cent) the sterility that had accompanied the menstrual disorders also disappeared. The author concludes that this method of treatment of menstrual disorders of functional nature in young women should be practiced only by an experienced roentgenologist in conjunction with a capable gynecologist.

Celiac Disease Case E Mondolfo—p 237  
Combined Treatment with Ethylchaulmoogra and Ethylmorphine Preparations in Diseases of Respiratory Tract F Falasca—p 245

**Arteriography of Thoracic Aorta**—Nuvoli performed arteriography of the thoracic aorta as a means of diagnosis in two cases of aneurysm by introducing the contrast medium into the ascending aorta in one case and into the left ventricle in the other. The puncture of the ascending aorta and the injection of 28 cc of a 100 per cent solution of sodium iodide, given at a constant pressure of 1,800 Kg during the injection did not produce complications in the first case while in the second the puncture of the left ventricle and the injection of the same amount of the solution, given at a constant pressure of 2,200 Kg, produced a syncope of brief duration followed by bradycardia (56) which lasted for thirty-six hours. The author believes that the syncope was due to the sudden distention of the myocardium and increased intraventricular pressure caused by the injection. He concludes that, while arteriography of the thoracic aorta by puncture of the ascending aorta is justified, puncture of the left ventricle should not be performed unless a substance giving satisfactory shadows without producing increase of the intraventricular pressure can be discovered.

## Prensa Medica Argentina, Buenos Aires

23 419 480 (Feb 12) 1936

- Bronchography in Asthma and Chronic Bronchitis N Romano R Eyberabide and R Tarradellas—p 419  
\*Atrophy of Hemidiaphragm Following Phrenicectomy J C Galan G Fonseca and J Dutreux—p 427

Fracture of Larynx Case A Bercovich—p 456

**Atrophy of Diaphragm Following Phrenicectomy**—Galan and his collaborators state that the results of experiments and necropsies prove that a well performed phrenicectomy with simple resection of the phrenic nerve results in the production of atrophy of the muscles of the corresponding hemidiaphragm. The anatomopathologic study performed by the authors in two cases in which the paralysis of the diaphragm had lasted for three years and a half and for eight months showed that the hemidiaphragm corresponding to the phrenicectomized side had undergone the following changes: intense atrophy of the muscle

a large part of which had disappeared and had been replaced by cellulosic fatty tissues, and intense alterations of the remaining muscular fibers, a large portion of which were dissociated and thinned. The authors state that the anatomopathologic changes of the hemidiaphragm after phrenicectomy prove that the phrenic nerve is the one which controls movement of the diaphragm and that, if there is any collateral motor innervation due to the presence of intercostal, either contralateral or accessory phrenic nerves, and other nervous impulses, it is insufficient to maintain the trophic conditions of the diaphragm after phrenicectomy and still more insufficient to maintain the motor functions of the diaphragm after the same operation.

**Failure in Tubal Sterilization**—Peralta Ramos states that all the methods used for permanent sterilization of women may prove inefficient in preventing pregnancy. The tubes may regain their functions by a partial reopening or by replacing themselves in the abdominal cavity after operations, such as simple ligation of the tubes, ligation followed by section, partial or complete tubal resection, peritonization of tubal stumps, transposition of the tubes or the combined methods of these operations. Total removal of both tubes followed by performance of a cuneiform excision of the fundus of the uterus and by a double seroserosal and musculomuscular suture is the operation that offers the best chance of preventing pregnancy, but even this is relative.

Study of Tuberculous Giant Cavities J L Garcia y Garcia Mifion—p 509

**Diaplacental Transmission of Tuberculosis**—Lucksch maintains that congenital tuberculosis is comparatively rare. The most frequent kind of transmission through the mother is by way of the placenta. However, there seems to be a disproportion between the incidence of placental tuberculosis and of congenital tuberculosis, and it seems difficult to understand why a tuberculosis of the placenta should remain without influence on the fetus. This problem and the frequent reports about filtrable forms of the tubercle bacillus induced the author to make further studies on the problem of congenital tuberculosis. He made histologic and animal experiments on placental materials, animal experiments with the blood of umbilical cords, and cultural and animal studies on the organs of fetuses. He frequently detected changes in the placenta and decidua which although they appeared nonspecific and did not present the typical aspects of tuberculosis, nevertheless were proved to be of a tuberculous nature in the animal test. Bacteriologic studies and animal experiments on the blood of umbilical cords and on the fetal organisms revealed the presence of filtrable forms of the tuberculosis virus. The author believes that the tuberculosis virus has become mitigated in recent times, pointing out that filtrable forms of the virus nonspecific tissue changes and mitigation of the causal organism mutually explain and support one another. It appears that infection as well as immunization of the fetus is much less frequent by the blood stream (by way of the placenta) than is the case after birth by the respiratory or digestive tracts or by the parenteral route.

**Atelectasis**—Knipping stresses that in this report he discusses only the type of atelectasis that develops in case of closure of the air passages. He disregards entirely compression atelectasis and atelectasis of the new-born. In case of acute atelectasis of larger parts of the lung the clinical aspects are usually pain on the diseased side particularly under the sternum, acceleration of the pulse and normal or elevated temperature. There is more dyspnea than cyanosis. The diseased side drags and seems smaller than the normal one. The intercostal spaces are retracted, the heart is displaced toward the diseased side and the diaphragm stands higher than normal. The respiratory sounds are reduced over the diseased part of the lung and there may be moist and sonorous rales. The percussion sound is shortened. Exudate and spontaneous pneumothorax can usually be ruled out. The shadow of the diseased

part of the lung is unusually homogeneous and readily differentiated from pneumonic and other infiltrates. However, in the majority of cases it is impossible to demonstrate the closure of the pertaining bronchus. Preceding pulmonary hemorrhage suggests a stenosing clot. But the occlusion may be caused also by syphilitic changes of the bronchial wall, bronchial calculi, bronchial edema, foreign bodies, aneurysms, swelling of the hilus glands and bronchial tumors. After discussing these various forms of atelectasis, the author gives his attention to the small atelectases and to the forms of atelectasis that develop in tuberculosis. As an accompanying symptom of tuberculosis, atelectasis may be a favorable factor. He discusses the therapeutic use of artificial bronchial closure and atelectasis. He suggests that it might be used in cavities that do not yield to pneumothorax therapy. To be sure, the artificial closure of the bronchus should not be irreparable.

**Desensitization of Mucous Membrane in Fractional Roentgen Irradiation**—Glauner points out that in the course of protracted fractional roentgen irradiations, particularly in case of malignant tumors of the oral cavity, of the pharynx and of the larynx, there frequently develop reactions in the mucous membrane, which Coutard has called radiation epithelitis. In order to reduce this epithelitis, the author sought to achieve a reduction in sensitivity by reduction of the blood perfusion of the tissues by means of painting with an epinephrine solution of 1:1,000. The anemia thus produced persists for from thirty to forty minutes or even for one hour, that is, for the duration of the irradiation. In order to demonstrate definitely that the epithelitis could be reduced, the author applied the epinephrine solution only to one side. He reports eight cases of oral carcinoma in which he resorted to the one-sided epinephrinization. In five of these cases the epithelitis was completely suppressed on the side that had been treated with epinephrine; in two other cases it was considerably less severe on the treated side, the remaining case cannot be estimated in this connection since epithelitis did not develop on the treated or on the untreated side.

**Late Effects of Epilation Irradiations**—Symann reports the results of examination of fifty-three patients who had been subjected to roentgen epilation during the years from 1917 to 1926 on account of fungus diseases (favus, microsporia) of the head. He points out that in recent years the question has been discussed whether roentgen epilation or thallium epilation is better. This induced him to investigate whether roentgen epilation produces permanent impairments. He found that in four of the patients the hair had become denser after the irradiation, while in eight others it had become less dense. In one case a roentgen lesion was noticeable in the form of atrophy of the skin and bone. The author assumes that the dosage had been incorrect in this case. Eight patients stated that their hair had become darker after the epilation, but in two others the opposite was the case. In fourteen patients the hair had become curly, but the curliness disappeared again in from twelve to eighteen months. One patient who had undergone roentgen epilation at the age of 2 years and 10 months, has complained since that time of frequent headaches and attacks of vertigo. The author thinks that the brain may have been impaired in this case owing to the greater ray sensitivity of the infantile brain. Intelligence tests revealed slight or severe mental deficiency in eighteen patients. However, no definite proof could be furnished that these subnormal intelligences were the result of the roentgen epilation, for in a number of cases the siblings of the patients also were of subnormal intelligence; others had had difficulties with their school work even before

the roentgen epilation, and in still others repeated infectious diseases make it appear possible that an encephalitis is responsible for the mental deficiency. Nevertheless there remain several cases of mental deficiency in which roentgen impairment seems possible.

- Influence of Pregnancy Urine on Surviving Rabbit Uterus K. Fukushima and H. Kameda—p 378

**Action of Estrogenic Substance on Blood Pressure**—Steinkamm and Giesen point out that Liebhart observed in normal, menopausal and castrated women and in those with hypofunction of the ovaries that the injection of estrogenic substance was followed by a reduction in the blood pressure. To determine whether this reduction in blood pressure was really the result of estrogenic substance, the authors made tests on thirty-five women belonging to the same groups as those examined by Liebhart. They observed that the intravenous injection of 200 mouse units of estrogenic substance resulted in a decrease in blood pressure, which in menopausal women reached as high as 25 mm of mercury. Since, at least in menopausal women, the blood pressure is unstable, the authors questioned the justification of ascribing the reduction in blood pressure to the action of estrogenic substance. They repeated the experiments with physiologic solution of sodium chloride and found that the blood sugar curve was influenced in the same manner as had been the case after the injection of estrogenic substance. They conclude that as yet it has not been proved that estrogenic substance reduces the blood pressure.

- \*Influence of Endocrine Organs on Genesis of Epilepsy J. J. H. M. Klessens—p 1119

**Influence of Endocrine Organs on Epilepsy**—From a curve indicating the initial ages at which epilepsy appeared in 750 men and 750 women, Klessens draws the following conclusions. Genuine epilepsy most frequently begins at prepuberty, but even in the presence of brain lesions the onset of the attacks may be between 10 and 12 years. The onset of epilepsy is causally related to the processes that lead to sexual maturity, which is shown by the observation that the brisk elevation of the curve indicating this maximal onset shows the same age difference between boys and girls that is shown by sexual maturing itself. After complete sexual maturity has been established, the onset of epilepsy becomes much rarer in boys after the fifteenth and in girls after the eighteenth year. This difference in the lowering of the curves between the sexes is based on delayed pubescence, which, as is the case with lasting incomplete maturity, is found in women more often than in men. The course of the curve in man as well as in woman, no matter how great the difference may be, supports the assumption that the mature gonad checks the irritability of the brain cells or at least originates other processes which promote cerebral response. As the most essential feature of epilepsy is the great lability of various functions, it is obvious that during the period of development epilepsy more often begins in women than in men, 44 per cent of the female cases beginning between 10 and 18 as against 33 per cent in the male. In opposition to the greater vulnerability of women during the period of sexual development, males are found to be more vulnerable in the early years of life showing 26 per cent of cases of epilepsy beginning during this period, while only 20 per cent develop in women, similarly, in adult life epilepsy more often sets in in men (14 per cent) than in women (10 per cent).

## DEMENTIA PARALYTICA

### RESULTS OF TREATMENT WITH DIATHERMY FEVER

SAMUEL H. EPSTEIN, M.D.

HARRY C. SOLOMON, M.D.

AND

ISRAEL KOPP, M.D.

BOSTON

Since 1917 fever therapy has become an established procedure in the treatment of dementia paralytica. As early as 1887, Wagner von Jauregg started to use fever-producing agents in the treatment of various psychoses of syphilitic origin. Within recent years many reports have accumulated from all over the world on the use of malaria in the treatment of dementia paralytica, and almost without exception these reports have been favorable. There is still some controversy regarding the mechanism of action of this method, and recently considerable interest has been given to the hypothesis that fever alone is the active agent in bringing about successful therapeutic results. Therefore various mechanical methods of producing fever have been devised in this country and have been employed over a period of about six years. Many of the recent reports on the use of hyperpyrexia in the treatment of neurosyphilis have been very favorable and in contrast, there have been a fewer number of unfavorable reports.

It is our purpose in this communication to present the results of the treatment of dementia paralytica with fever produced by diathermy in the Boston Psychopathic Hospital, where this method has been used since the early part of 1931. This report includes a series of thirty-three patients to whom we gave diathermy treatment between February 1931 and February 1935 and the results were analyzed as of February 1935. Therefore the longest period from the time the treatment was given to the time of the analysis was four years, whereas the shortest period in which the patients were studied after the treatment was one year. As will be shown later, some patients in the series received other treatment prior to or subsequent to the treatment with diathermy, but the common factor in the treatment of all the patients was diathermy. This group of cases and the results obtained therefore are not exactly comparable to other series reported by other authors. As previously noted in the reports on malaria

treatment<sup>1</sup> there are hardly two groups of cases in the literature that are comparable with each other, as many variants enter into consideration, such as the exact type and amount of treatment, the selection of patients, and the length of time the patients were followed before the report was made not to mention the personal equation that enters into the conclusions reached. As one goes through the reports, one is struck by the relatively small number of cases that were followed up after diathermy treatment. Therefore percentage statistics in the individual reports are not significant, although it may be fair to compute percentages on the basis of the total number of cases reported in the literature. There are, however, only twenty reports to be found in a search of the literature, including papers dealing with diathermy, radiotherapy, electric blanket and electric cabinet. It is fair to assume that emotion clouds the judgment, in some cases at least, as the enthusiasm of using a new procedure is likely to lead to wishful thinking. On the other hand, there is reason to believe that in at least one instance of reported poor results the desire to defend the superiority of malaria has clouded the judgment.

Table 1 gives in tabular form the reports of all the series of cases of dementia paralytica treated with diathermy and related forms of mechanical hyperpyrexia. In the mass statistics given in this table, made up from series of cases varying from a small number of six to the largest group of 133, it will be seen that the majority of the series number less than fifty cases. It is also apparent that the results vary greatly. For example, Freeman, Fong and Rosenberg<sup>2</sup> report no good remissions in a series of fifty cases treated, while Neymann and Koenig<sup>3</sup> report twelve good remissions and thirty-eight partial remissions out of a total of fifty cases treated with diathermy. The total number of cases reported in this table is 648, of which 177 cases are considered to have good remissions and 260 cases are having a partial remission. This gives a percentage of 27.1 for good remissions and 40.1 for partial remissions.

As in our previous reports on the treatment of dementia paralytica by triparasamide and by malaria, in each case in this series diagnosis was made on the basis of clinical studies and on the spinal fluid, it being held requisite for the diagnosis that the spinal fluid give the typical strong reaction characteristic of the disorder. Table 2 gives a detailed analysis of all the cases in this series. The period of observation after the onset of the symptoms in these cases varied from

two months to four years. It is to be pointed out that those patients who were followed for less than one year died and that no living patient in this series was followed for a period of less than one year.

The results of the treatment are analyzed from two points of view: (1) the clinical status of the patient and (2) the observations on the spinal fluid. Our customary classification consists of the following groups: 1. Under "improved and working" are patients who have made an improvement sufficient to allow them to resume their places in the life of the community and return to work. This group is comparable

to that described in the literature as having "good remissions." 2. We classify as "improved but not working" the group of patients who have shown an improvement which allowed them to live outside a hospital that is those who had become socially adjusted but who were not self supporting. 3. We consider as "improved but hospitalized" those patients who have shown physical and mental improvement who are apparently maintaining a stationary condition so far as the disease is concerned and who are able to adjust well and work in the environment of a hospital for patients with mental disease. 4. Patients who have shown little or no improvement are considered as "unimproved." Our fifth group consists of patients who have died of any cause.

In table 3 we present an analysis of the clinical status of the entire group in 1935. According to our analysis, eight patients out of the total number of thirty three were improved and working, and seven patients were living outside the hospitals although not self supporting, four patients, while remaining hospitalized, were known to be improved and were able to do work in an institution and had parole privileges, four patients were living but unimproved, ten patients had died.

In table 4 we present the observations on the cerebro spinal fluid. The observations for only thirty two patients are given because in one case it was not possible to make an examination of the spinal fluid subsequent to the treatment. We will not consider the serologic reaction of the blood, because experience has repeatedly indicated that there is no relation between the course of the disease and the reaction of the blood, either with or without adequate treatment. The spinal fluid examination gives more satisfactory evidence of the effect of treatment on the disease process. It has long been our opinion that a completely normal spinal fluid is a good indication of an arrest of the activity and progress of inflammation of the brain and represents an arrest of the disease. A completely normal spinal fluid was obtained in seven patients of the series, in four additional patients the condition of the spinal fluid was greatly improved, in five patients the spinal fluid showed moderate improvement and in sixteen it was considered as unimproved. By a "completely normal fluid" is meant a fluid showing a cell count under five, a negative reaction for globulin, a total protein content under 40 mg per hundred cubic centimeters, a negative reaction to the colloidal gold test and a negative Wassermann reaction with 1 cc of fluid. A "greatly improved" fluid was one in which the reactions were very weak, approaching but not quite negative, whereas a "moderately improved" fluid showed a reasonable reduction from the original strongly positive formula.

We have previously pointed out, as have many others, that there is no complete parallelism between the clinical results and the observations on the spinal fluid in cases of dementia paralytica under treatment. However, even in our reports of the results of treatment with trypanamide alone there appeared to be a fairly close correlation between the clinical and the serologic results. As regards our series of patients treated with diathermy, again some degree of correlation may be seen in table 5. This reveals the striking phenomenon that none of the fourteen patients who clinically were unimproved had a normal spinal fluid and in only two patients was the spinal fluid substantially improved. One can conclude that there is some correlation between the clinical status and the reaction of the spinal fluid, at least so far as the group that showed no improvement is concerned. With regard to the patients who were clinically improved, it will be seen that of the fifteen patients eight, or approximately one half of them, had completely normal or nearly normal spinal fluids.

It has been repeatedly emphasized that at least two factors play a role in the spinal fluid results following effective treatment, namely the time element and the number of subsequent injections of trypanamide. In any series of patients with dementia paralytica under treatment, more and more patients show normal cerebro spinal fluids as the years go by. It is also true that

4. Solomon H C and Epstein S H. Dementia Paralytica. Results of Treatment with Trypanamide. Arch Neurol & Psychiat 23 1716 (June) 1935.

the amount of tryparsamide given has an important influence on subsequent normality of the spinal fluid. We have stated in a previous communication<sup>5</sup> that with the persistent use of tryparsamide negative spinal fluid reactions are practically inevitable, irrespective of the

after diathermy fever. It should be noted that one year or more had elapsed before the spinal fluid became normal in all but one of the cases. With regard to that single patient, it must be pointed out that he had a spinal fluid which was only weakly positive before dia-

clinical status. Table 6 shows the time element and the amount of treatment before and after diathermy fever in the seven cases of this series in which the cerebrospinal fluid became normal. From a study of so few cases it is not possible to draw any conclusions with regard to the effect of the amount of treatment

thermy treatment and considerable treatment had been given previously. Consequently, it may be assumed that the final serologic result in this case was attributable, at least in part, to the treatment other than diathermy fever.

The question of the duration and degree of fever necessary to produce successful therapeutic results is still undetermined. Various authors differ on this

<sup>5</sup> Solomon H. C. and Epstein S. H. Tryparsamide in the Treatment of Neurosyphilis. New York State J. Med. 31: 1012 (Aug. 1931).

point Among those who sponsor prolonged fevers (five hours) at high levels (106 F) are notably Neymann<sup>5</sup> and Simpson,<sup>6</sup> whereas Perkins<sup>7</sup> believes that short bouts of fever of around 104 F are just as effective in bringing about clinical remissions From

our own experience it has not been possible to draw any hard and fast conclusions Table 7 gives an analysis of our cases from the standpoint of the amount of fever given and the clinical results obtained in the individual case It will be seen that there are no significant differences in the number of diathermy treatments among the various groups of clinical results It is further apparent that the few cases in which fevers were prolonged at high temperature levels were about equally divided between the improved and the unimproved groups However, it must be noted that those patients who did receive a large number of diathermy treatments at high and prolonged temperatures

were those who were not responding well to treatment and therefore represent relatively recalcitrant cases

It is quite possible that our results in the total group would have been much better had the treatment been more prolonged and at a higher temperature That is a point about which there is no unanimity of opinion, nor is there any adequate experimental control The same situation holds true for malarial paroxysms There are some statistical data, notably those of Bunker and Kirby,<sup>8</sup> which tend to show the optimum number of paroxysms and height of malarial fevers that produce the best therapeutic results On the contrary, there are some good results reported in the literature which occurred with a relatively small number of malarial paroxysms at low temperature levels All in all, the evidence seems hardly convincing and it still remains an open question as to what is the optimum condition for the most effective malarial and diathermy fever therapy

In the detailed analysis of cases outlined in table 2, there are a few points of interest that merit consideration Patient 19 had severe convulsive seizures dur

was kept under observation for a total period of eight years, it is to be noted that this patient had had treatment with rat-bite fever four years prior to his diathermy treatment. In spite of this, his serologic reaction remained unimproved and his clinical condition was such that institutionalization was necessary during most of the time.

In our series of thirty-three patients treated with diathermy there occurred one definite relapse. This was in case 6, in which a normal spinal fluid had been obtained in one and one-half years after the fever therapy and in which the clinical condition was considered as arrested. Shortly after this study was made, which was nearly four years after diathermy fever therapy had been used in this case, the patient was brought back to the hospital and showed marked mental changes and a fairly strong spinal fluid. This is of extreme importance, because in our report<sup>1</sup> covering 173 patients treated with malaria we have not encountered a single relapse.

According to the figures in this relatively small series of patients, it would appear that 30.3 per cent of the entire group had died by the end of the four year period of observation and 27 per cent within two years after treatment. The only report in the literature covering a four year period is that of Freeman and his associates,<sup>2</sup> and in that series of fifty patients, 28 per cent had died. Most of the other reports show a much lower percentage of deaths, but it is to be noted that those patients were followed for relatively short periods of time. At any rate, the mass statistics of the entire series reported in the literature show a figure of 8 per cent for the death rate of patients with dementia paralytica treated with artificial hyperpyrexia.

The longevity of untreated and treated patients with dementia paralytica is an interesting subject for comparative study. The life expectancy for untreated patients is considered to be about two and one-half years in man. In marked contrast is the period of survival of the patients in our malaria series,<sup>1</sup> in which

TABLE 8—Analysis of Ten Cases in Which Death Occurred After Treatment with Diathermy

Table 8 shows an analysis of the deaths in this series. It will be seen that of the ten patients who died the duration of life was not greater than that of the average untreated patient with dementia paralytica. Of the ten deaths, all but one occurred within one and one-half years, the majority of the patients having died within a few months after the diathermy treatment. None of these patients showed any clinical improvement and only two of them showed any appreciable improvement with regard to the response of the spinal fluid before death. The latter point must be evaluated in the light of the fact that the patients died sooner than the time when spinal fluid changes usually occur following treatment. The causes of death as listed in the table indicate that the parietic disease was active in most of the cases with one possible exception. Patient 27 was known to have diabetes, underwent treatment and died one and one-half years later without having a postmortem examination. In the one patient 26 who lived for three years after treatment and finally succumbed to a renal infection postmortem examination of the brain showed evidences of dementia paralytica.

77.5 per cent of the total number of 173 patients had lived three or more years. In this series 14.8 per cent of the patients died within two years after treatment. Likewise, in our series of eighty-one patients treated with tryparsamide<sup>4</sup> the patients dying within two years represented only 13.5 per cent of the series. Table 9 shows the comparative figures regarding longevity. It will be seen that the figures are not exactly comparable, since the cases compiled from the literature were not followed for any great length of time, most of them having been followed for considerably less than two years. For this reason the percentage of patients dying after hyperpyrexia treatment in these series is given as 6.1. This figure, we believe, would be greatly increased if the cases had been under observation for two or more years.

There is a striking contrast between the mortality rates of patients treated with malaria and tryparsamide on the one hand and by diathermy on the other. In the mass statistics given by Moore,<sup>9</sup> based on an analysis of 5000 cases treated by malaria the deaths

<sup>9</sup> Moore, J. E. The Modern Treatment of Syphilis. Springfield, Ill. Charles C. Thomas, 1933.

during or shortly after treatment form 10 per cent of the cases. In our malaria series the death rate covering a nine year period is 22.5 per cent. Of the thirty-nine deaths recorded, twenty-six had occurred within two years following treatment. The death rate in our tryparsamide series<sup>4</sup> is 6.2 per cent, and it is to be noted that none of the fourteen deaths occurred in less than two years after treatment, and in only five cases did death appear to be due to unarrested dementia paralytica.

It is of some interest to compare the results in this series of patients who were treated by diathermy with

TABLE 9—Longevity Percentage of Patients Dying Within Two Years after Treatment

Malaria Series, 178 Cases	Tryparsamide Series 81 Cases	Diathermy Series <sup>4</sup> 33 Cases	Hyperpyrexia Series 489 Cases*

\* Hyperpyrexia series compiled from literature followed less than two years.<sup>5</sup> Freeman's series followed four years had 28 per cent mortality.

those in the literature who received other forms of therapy. The clinical results are tabulated (table 10) and show clearly that malarial treatment gives the highest percentage of improvement, with tryparsamide treatment a close second, whereas treatment with artificial hyperpyrexia gives a low percentage of improved cases. Table 11 gives the comparison of serologic results among our three series of patients treated respectively by malaria, tryparsamide and diathermy. It will be seen that 21.9 per cent of the total number of cases treated by us with diathermy showed a normal spinal fluid, which is a substantial figure although distinctly less than our malaria and tryparsamide series. The literature on diathermy treatment has been combed with a view to computing the percentage of favorable serologic results but it is to be regretted that, of the total number of 648 cases reported in the literature, serologic data are available in only 237 cases. Among these cases no detailed analyses of the spinal fluid examinations are to be found, and we note that the

TABLE 10—Comparison of Clinical Results

	Malaria Series 178 Cases	Malaria Series 5 000 Cases*	Hyperpyrexia Series 648 Cases†	Diathermy Series <sup>4</sup> 33 Cases	Tryparsamide Series 81 Cases
Arrested	48.5%	45.0%	27.1%	24.2%	42.0%
Partially improved	15.2	25.0	40.1	33.3	29.0

\* J. E. Moore's mass statistics compiled from the literature.  
† Hyperpyrexia series compiled from literature.

spinal fluid following treatment was improved in sixty-four cases, and in an additional eight cases, reported by Simpson,<sup>6</sup> the spinal fluid Wassermann reaction was found to be negative. Therefore we have to compute percentages on the basis of our own small series of thirty-three cases treated with diathermy.

The foregoing account of therapeutic results of diathermy fever therapy includes follow-up treatment with tryparsamide. These results are comparable to our malaria series of patients, to whom other forms of treatment in addition to fever were also given. The importance of our results herein reported lies in the contrast between the two febrile methods of treatment. In our hands, and in a review of the literature as well,

diathermy treatment did not give as good results as malaria. On the practical side there is considerable hazard in the diathermy method, the patients are extremely uncomfortable and require constant supervision during the treatment, and the expense is much greater than with the malaria method. The only advantage of diathermy treatment is that it can be used in some cases in which malaria cannot be given, and in other cases it can be used in addition to malaria. We are not convinced that diathermy is an advantageous substitute for malaria, either from the review of the literature or from our own experience.

#### SUMMARY

1 A review of the literature of the results of treatment of dementia paralytica with fever produced by diathermy and related mechanical modes of hyperpyrexia indicates that, out of a total of 648 cases reported between 1929 and 1935, good remissions were reported in 27 per cent.

2 In our series of thirty-three patients who were treated by diathermy between February 1931 and February 1934, according to our analysis, made in February 1935, eight patients were improved and working, and an additional seven patients were improved but not self supporting. Four patients, while remaining hospitalized, were known to be improved. Four patients were living but unimproved, and ten patients had died.

TABLE 11—Comparison of Serologic Results

	Malaria Series 178 Cases	Tryparsamide Series <sup>4</sup> 81 Cases	Diathermy Series <sup>4</sup> 33 Cases
Normal	36.7%	37.5%	21.9%
Greatly improved	20.7	16.3	12.0
Moderately improved	18.3	10.0	15.6
Unimproved	24.3	36.2	50.0

3 In one case out of our total series there was a definite clinical and serologic relapse four years after the administration of diathermy fever therapy.

4 There appeared to be a correlation between the clinical status and the reaction of the spinal fluid in this series. Of the fifteen patients who were clinically improved, eight, or approximately one half of them, had completely normal or nearly normal spinal fluids.

5 With regard to the duration and degree of fever productive of the best therapeutic results, it is not possible from our experience to draw any hard and fast conclusions. But it is quite possible that our results in the total group of cases would have been much better if the diathermy treatment had been more prolonged and at a higher temperature level.

6 The longevity figures based on the percentage of patients who died within two years after treatment indicate that 27 per cent of the diathermy series represent deaths which occurred within two years after treatment. This is contrasted with the figure 14.8 per cent for our malaria series and 13.5 per cent for our tryparsamide series previously reported.

7 A comparative study of the clinical results among patients treated with malaria, artificial hyperpyrexia including diathermy, and tryparsamide indicates that the best remissions are obtained in a little over 45 per cent of the malarial treated cases and 42 per cent of the cases treated by tryparsamide, contrasted with 27 per cent of the cases treated by artificial hyperpyrexia.

8 A comparative study of the serologic results in our series of cases indicates that about 22 per cent of our diathermy series showed a normal spinal fluid following treatment, in contrast to 37 per cent obtained in our malarial and tryparsamide treated cases

#### CONCLUSION

In our hands, fever produced by diathermy has some value in the treatment of dementia paralytica but it is not so good as malaria therapy. Likewise, in a review of the literature it fails to prove to be a valuable substitute for malaria, although from our studies it appears to have distinct therapeutic value. Moreover, it would seem that treatment with tryparsamide is capable of producing beneficial results similar to those produced by malaria therapy.

### RAGWEED (CONTACT) DERMATITIS

OBSERVATIONS IN FORTY-EIGHT CASES AND REPORT OF UNSUCCESSFUL ATTEMPTS AT DESENSITIZATION BY INJECTION OF SPECIFIC OILS

LOUIS A. BRUNSTING, M.D.

AND

DONALD H. WILLIAMS, M.D.

Fellow in Dermatology and Syphilology, the Mayo Foundation  
ROCHESTER, MINN.

In a previous paper we<sup>1</sup> reported our experience with eighteen patients who presented a recurrent, eczematous seasonal dermatitis due to sensitivity to oil of ragweed. During the seasons of 1934 and 1935 we observed thirty similar cases, and a summary of our observations for the entire group of forty-eight cases forms the basis of the present report. In addition we shall describe the results of attempts at desensitization of twenty-four of these individuals who were given injections preseasonally of the specific oils to which they were found to be sensitive.

#### SYMPTOMATOLOGY

The most typical feature of ragweed dermatitis is its seasonal incidence, coinciding as it does with the season of pollination of the weeds during the summer and autumn months and clearing spontaneously with the first frost, at least in the earlier cases. The eruption, which is at first limited to the exposed skin of the face, neck and arms, is characterized by diffuse erythema and superficial desquamation and by a minimum of vesiculation, it is extremely pruritic. On continued exposure, the eczematous manifestations become more chronic, lichenification and fissuring occur and occasionally, involvement of the entire surface of the body, with resulting total disability.

Men are chiefly affected, usually farmers or those who frequent rural districts in work or sport. In the present series there were forty-four men and only four women. The condition affects adults exclusively and seasonal recurrences are the rule. In the forty-eight cases herein described the average age at which symptoms began was 39 years and the average duration of recurrences covered twelve seasons. There were three men in the group who had each been troubled each season for more than twenty years.

#### PATCH TESTS

Patients were tested by patch applications of a wide range of common cutaneous irritants, including weeds, chemicals and cosmetics. The unbroken skin of the upper portion of the back was the usual site chosen. In the case of weeds, pyrethrum or orris root the unwashed powder was used in the case of chemicals, a standard solution not irritating to the normal skin, was used. Test materials were allowed to remain in place from twenty-four to forty-eight hours, and readings were made at the site of testing at intervals ranging from one to seven days after removal of the patch. Those reactions showing edema or vesiculation or both were graded positive, very weak reactions with no more than transient changes were not classified as positive reactions.

Although our chief interest lay in the study of reactivity to the ragweeds, most patients were tested to a variety of common cutaneous irritants in order to appraise the trend and range of sensitivity of the group of patients as a whole (table 1). There were 131 positive patch reactions out of the total number of 597 tests that were applied, and the greater share of positive reactions were to the ragweeds. Of thirty-five tests made to pyrethrum, six were positive, of a similar number to turpentine the same number were positive, although not necessarily in identical patients.

In most instances sensitivity was multivalent; however, there were nine instances in which sensitivity was limited to short ragweed alone and in one instance to burweed marsh elder alone. There was sensitivity to

short ragweed and burweed marsh elder in the same patient on four occasions, to short ragweed and western ragweed once and to burweed and western ragweed once. In these cases of univalent or bivalent sensitivity an average of fifteen patch tests were performed in each case.

A comparative analysis of tests made to the various species of ragweed (short, giant and western ragweed, and burweed marsh elder and cocklebur) is of special interest. Records of tests on thirty-eight patients to these five varieties of ragweed were sufficiently complete to permit of tabulation (table 2). Short ragweed

Negative	0	—	3
Total	3	32	35

On the other hand, a summary of the patch reactions to short ragweed and giant ragweed in the same group of patients presents a sharp contrast (table 3). There was a positive reaction to giant ragweed in only three instances among the thirty-eight patients tested. Presuming that the irritating fraction of the plant or pollen is contained in the oil, we might question whether there was sufficient oil in the pollen of the giant ragweed used in our tests to produce a positive reaction. There was no lack of oil. In fact, the unwashed pollen of giant ragweed invariably yields more oil proportionately than the pollen of either burweed marsh elder or short ragweed.<sup>2</sup> From our observations we must assume that the oil of giant ragweed lacks the irritating quality of the oil of short ragweed. Perhaps a further study of the unsaponifiable, as compared to the saponifiable fractions of the two oils, following the suggestion of Engman and others,<sup>3</sup> will throw more light on the subject. In any event the discrepancy exists and is of more than passing interest in view of the evidence which tends to show that the two varieties of ragweed from the standpoint of the active protein constituents are otherwise so nearly identical.<sup>4</sup>

#### ALLERGIC BACKGROUND

In our previous report we<sup>1</sup> stated that we found there was no more than a casual relationship between contact sensitivity and the allergic state. In the present series of forty-eight cases of ragweed dermatitis there were ten patients who gave a history of allergic associations in the form of infantile eczema, hay fever, asthma or the like in themselves or among members of their families. In these ten cases we found positive reactions of an urticarial type to the intracutaneous injection of assorted proteins of foods or inhalants.

Six of these ten reactors responded with an urticarial wheal to the intracutaneous injection of protein of short ragweed. A special study was made in this regard of twenty-eight patients who gave a positive reaction to the patch test to short ragweed and who were tested by the intracutaneous injection of the protein fraction of the same plant; in this group there were only the six positive responses which were just mentioned.

#### ATTEMPTS AT TREATMENT BY DESENSITIZATION

Brown, Milford and Coca,<sup>5</sup> after pointing out that the contact irritant of ragweed was an oil, recommended that such specific oil be given by injection to patients with ragweed dermatitis for purposes of desensitization. During the seasons of 1933, 1934 and 1935 we selected certain patients with ragweed dermatitis for trial with this type of treatment.<sup>6</sup>

In most instances patients were given the oil of mixed ragweed, that is, equal parts of short and giant ragweed by intramuscular injection in doses ranging from 0.1 to 0.5 cc in varying intervals of time and for varying numbers of treatments. For certain patients who presented patch reactions of the multivalent type an attempt was made to include oils comparable to all the types of irritants that gave positive reactions, but this was not always feasible. A few individuals with a history of recurring dermatitis of this type came to us with the diagnosis having been established elsewhere and with a history of having received previous injection.

tions of specific oil intramuscularly. When it could be arranged, we endeavored to give the oil treatment periodically, beginning in the spring and carrying through the early summer months in an attempt to avoid the expected seasonal recurrence in the fall.

The results for those patients who received oil treatment of this type at any time before 1935, and including the spring season of 1935, were judged by the

6 The oil used in all cases was the standard material prepared by Lederle Laboratories, Inc. in 1 per cent dilution in almond oil.

degree of relief obtained during the ragweed season in the fall of 1935. A summary of the type of treatment given and of the results in twenty-four cases is presented in table 4. In only two cases was there no relapse (41 and 51). Both of these patients were men who were able to carry on their usual work in the rural districts during the fall of 1935 without recurrence of dermatitis, whereas for several seasons previously they had had annual attacks of dermatitis. During 1934 one of them had been given six injections of the oil of mixed ragweed, and the other, four injections of oil of mixed ragweed and two of oil of burweed marsh elder. In three other cases (25, 40 and 42) treatments were of doubtful benefit, and in these three cases the oil treatments numbered six, three and seven, respectively. In every one of the remaining nineteen cases there was recurrence of dermatitis during the season of 1935. Unfortunately, in the latter group there were one or two patients who received no more than two treatments, on the other hand there were five who obtained no measure of relief who had received eighty-five, twenty-one, thirty-six, twenty and twelve injections, respectively. Six patients, each of whom had received oil treatments, were examined on subsequent occasions and patch tests to short ragweed were made, in no instance was a negative reaction obtained.

In an analysis of the results of treatment it does not appear that there is any correlation between the patients who received benefit and the univalence or multivalence of the respective positive patch reactions in these cases. Several of the patients who obtained no relief were treated through more than one year, in two cases for three years, and preseasonally in each instance. Others<sup>7</sup> have mentioned that there was relief from symptoms of pruritus within a period of a few hours following injection of the oil of the specific irritant. We noticed such a favorable influence on symptoms in only one instance. On the other hand we have records of thirteen patients who were unfavorably influenced by the injections of the specific oil in doses as low as 0.1 cc intramuscularly, or even by the application of the irritant to the skin by patch test. In three instances in which there was a flare of this type the eruption became more generalized, and in one case it became universal.

The discouraging results of attempts to confer immunity in this type of contact dermatitis is in agreement with the lack of success which we have had in other types of contact sensitivity, namely those in which there is reaction to oils of ivy, chrysanthemum and pyrethrum. This is in harmony with the observations of investigators over the country who have communicated to us their personal experience. Scattered instances have been reported of occasional patients with contact dermatitis who have received benefit from this type of desensitization by oil treatment, but they are the exception rather than the rule. It is obvious that further study is needed with regard to the particular fraction of the oil that contains the specific irritant capable of producing sensitivity. Furthermore, now that it has been shown that this type of contact sensitivity to specific irritants can be induced experimentally in animals, there is need for controlled attempts at desensitization before the method, at least in its present stage, can be generally recommended for use in man.

## SUMMARY

Forty-eight patients had the typical syndrome of recurrent seasonal dermatitis in the fall due to sensitivity to oil of ragweed, and the reactions of these patients to nearly 600 patch tests to common cutaneous irritants were studied.

Outstanding positive reactions were obtained by the patch tests to short ragweed, burweed marsh elder and western ragweed. Positive reactions to patch tests of giant ragweed were strikingly insignificant.

Twenty-four patients who were selected for attempts at desensitization were given a total of 282 injections intramuscularly, of specific plant oils, 252 of which were of oil of mixed (short and giant) ragweed, during the two or three years preceding 1935 and including the spring of 1935. In nineteen of these twenty-four cases in which oil treatments in varying amounts had been given there was no relief of symptoms, as shown by relapse during the expected season of dermatitis in the fall of 1935.

## CAUDA EQUINA SYNDROME FOLLOWING SUBARACHNOID ALCOHOL INJECTION

## REPORT OF TWO CASES

LOUIS L. TUREEN, M.D.

AND

JOSEPH J. GITT, M.D.

ST. LOUIS

In describing his technic of the subarachnoid injection of alcohol for intractable pain, Dogliotti<sup>1</sup> warns against possible sequelae, particularly of injury to the cauda equina. Transient bladder and bowel embarrassment following lumbar sac injection is mentioned by those who are familiar with this procedure. A recent report by Sloane<sup>2</sup> described the permanent relief of pain, but sphincteric disturbances which had developed had been persisting for eight months when the report was made.

In the two cases described in this paper, very transient relief was afforded from the pain for which Dogliotti's treatment was used. On the other hand, the bladder disturbances have persisted for over a year in one case and for the entire period of observation (eight months) in the second case. Furthermore, it is of significance that although the lesion produced by the alcohol was unilateral, there nevertheless resulted a profound urinary incontinence.

## REPORT OF CASES

CASE 1—A tailor, aged 50 admitted to the Neurological Service of the Jewish Hospital, Oct. 23, 1934 complained of constant pain in the right lower extremity of two years' duration. On physical examination he was found to be suffering from a far advanced hypertrophic spondylitis of the fifth, sixth, seventh, eleventh and twelfth dorsal and the third and fourth lumbar spinous processes, and a sacro-iliac arthritis on the right. As a result he exhibited all evidences of an involvement of the right sciatic nerve, with a mild foot drop, loss of the achilles tendon reflex and vaguely defined sensory disturbances of the foot. Spinal puncture gave normal results. The left lower extremity was uninvolved.

From the Neurological Service of the Jewish Hospital, the Department of Internal Medicine and Neurology, Washington University School of Medicine and the Barnes Hospital.

November 7, with the patient lying on his left side and the right hip sharply elevated, 1 cc of absolute alcohol was injected into the subarachnoid space between the third and fourth lumbar spines. The patient was kept in this position for about thirty minutes, and on his left side for several hours. There was no immediate reaction. That night the patient was able to sleep comfortably for the first time in two years. The following morning he complained of numbness in the right lower buttock. He was unable to void for forty-eight hours. Then a urinary anesthesia and incontinence developed. The bladder was distended and palpable through the abdominal wall. Constipation was also present. November 9 he exhibited a loss of pain and touch sensation in the distribution of the second, third, fourth and fifth sacral segments. There was anesthesia of the right half of the penis and scrotum. Sciatic pain had disappeared entirely and the patient was quite happy, despite the development of cystitis and an overflow bladder.

November 14, analgesia persisted in the four lower sacral segments on the right, but the sense of touch was not so widely affected. The right half of the scrotum and penis was anesthetic to pin prick. The anal sphincter was anesthetic to pin prick only on the right. Pain was perceptible on the left. The anal sphincter was relaxed and not under voluntary control. The palpating finger within the canal was not felt. There was a partial loss of voluntary urinary control although the bladder emptied intermittently instead of dribbling constantly as it had done at first. Following the voluntary voiding of 150 cc of urine, 650 cc of residual urine was removed by the catheter. November 18 the patient seemed to recognize the urge to void and would call for the urinal. There was no incontinence, but during micturition he was totally unaware of the passage of urine. Sensation of touch was slowly returning, but pain sense was still absent in the primarily involved areas. Dissociation of pain and touch in the right half of the penis and scrotum seemed to have occurred, pain being absent.

November 22 the patient was discharged from the hospital, completely freed from his sciatic pain but with a persisting cauda equina syndrome. The sciatic pain recurred November 28 and has continued unabated to the date of the last examination Dec 19 1935. At this time there was no subjective sensation of a full bladder, urination or desire to defecate, he had taught himself to go to the toilet at stipulated times during the day.

CASE 2—A woman, aged 47, white, a housewife, admitted to the Medical Service of the Jewish Hospital, Aug 5, 1934, complained of pain in both legs of sixteen days' duration. She was known to have diabetes and had been in the hospital three years previously with circulatory disturbances of both legs, the symptoms lasting for seven months. In March 1934 there had been indeterminate renal symptoms for eleven weeks. Two weeks prior to admission the patient suffered severe pains in both legs, which became discolored. Vomiting occurred.

Physically the patient was somewhat undernourished. She was confused, the memory was faulty and there was a marked emotional instability colored by suicidal ideas. Because of her irritability she was difficult to manage and had been subjected to large doses of morphine, to which she had become addicted. She suffered from a moderately enlarged heart, which was fibrillating. Systolic and diastolic murmurs were heard at the apex. The heart tones were of poor quality. The blood pressure was 170 systolic 90 diastolic. There was a moderate degree of arteriosclerosis of the upper extremities. On admission she was unable to move the right leg and within twenty-four hours she lost motor power in the left leg. Over the dorsal surface of the right foot near the metatarsophalangeal joints there was a reddish purple discoloration. The toes of both feet were cyanotic more so on the right. The legs were tender to palpation and manipulation. On the small left toe was a green crusted lesion. The dorsalis pedis and the posterior tibial pulsations were not obtained on either foot. The popliteal pulse could be felt on the left, but its presence was doubtful on the right. Both femoral arteries had normal pulsations. Laboratory observations included a diabetic sugar tolerance curve and a slight retention of nonprotein nitrogen (36.6 mg per hundred cubic centimeters). The electrocardiographic diagnosis was left ventricular preponderance and auricular fibrillation. Roentgen examination demonstrated the presence of calcification of the common iliac arteries.

The patient rejected the recommendations of periaarterial sympathectomy and of chordotomy. She submitted to injections

of absolute alcohol into the subarachnoid space and on Aug 21, 1 cc was injected in the second lumbar interspace. This was entirely without relief or complication. November 27, at 10 a. m., the injection of 1 cc of absolute alcohol was repeated in the same space. The following morning there was no subjective improvement. Sensory examination could not be done satisfactorily, but apparently no sensory changes had taken place. At 5 p. m., November 28, the bladder was dribbling, 1,200 cc of residual urine was removed by catheter. No new sensory changes could be detected in the legs. On the morning of November 29 the patient reported that she had less pain. The night's sleep had been without discomfort. There was a small area of anesthesia on the anterior aspect of the right thigh and around the anus. There were hypesthesia and analgesia over the right thigh, anteriorly and posteriorly. The left thigh was analgesic to pin prick front and back, but touch was intact. Both legs and feet were hyperesthetic, all touch sensation was interpreted as pain. All symptoms of pain returned on December 3. On this day all stimulation of the lower extremities was painful. Incontinence of the bladder continued. Eventually psychotic episodes appeared necessitating the transfer of the patient to a sanatorium. Before her removal from the hospital, neurologic examination, April 13 1935, demonstrated the presence of anesthesia of the fourth and fifth sacral segments on the right, with a slight extension of the anesthesia to the left perianal region. The remainder of the lower extremities was hyperesthetic to touch. Incontinence of the bladder persisted.

#### COMMENT

The action of alcohol on nerve roots is to fix the tissue, thereby blocking all impulses. If it were possible to destroy in a selective way the fibers that transmit pain, leaving all other fibers intact, an ideal therapeutic measure would be available for the relief of intractable pain. Dogliotti<sup>3</sup> and Stern<sup>4</sup> state that the injection of alcohol intraspinaly offers this opportunity. They maintain that the unmyelinated pain fibers of the posterior roots of the spinal nerves are blocked, while the myelin sheaths of the fibers of touch and position sense protect their axis cylinders from damage. Manipulations of the body during the injection permit the anterior roots to escape, while selection of the spinous interspace for injection offers a reasonable degree of certainty in limiting the involved nerves to the desired levels.

The method is based on the principle that absolute alcohol, being lighter in specific gravity than cerebrospinal fluid, will rise to a superior stratum before it diffuses and mixes with the cerebrospinal fluid. This can readily be demonstrated in vitro. The side that is uppermost is the one affected by the alcohol, permitting the production of unilateral block, and by elevating the desired region of the spine sharply it is possible to limit the number of involved nerves to some reasonable extent. However, it is probable that the alcohol frequently diffuses over a wider area and involves more nerve roots than is desired.

Dogliotti cautions against possible cauda equina complications in lumbosacral injections because of the close grouping of many nerve roots in a small confined space. Less selectivity is possible here than in the dorsal region, and for this reason he recommends the use of not more than 0.6 cc of absolute alcohol in lumbar sac injections. By excessive tilting of the pelvis it is possible to affect the lowest sacral roots on both sides, which may also occur if too low an interspace is selected for the injection, with a resulting sphincteric disturbance.

<sup>3</sup> Dogliotti, A. M. Recent Methods of Analgesia and Anesthesia. *M. Rec.* 140: 347 (Oct 3) 1934.

<sup>4</sup> Stern, E. L. Relief of Intractable Pain with Intraspinal Alcohol. *Am. J. Surg.* 25: 217 (Aug.) 1934. The Intraspinal (Subarachnoid) Injection of Alcohol for Thrombo Angustis Obliterans. *M. Rec.* 141: 244 (March 6) 1935.

However, Dogliotti observed in no instance of his series of cases sphincteric disturbances of more than twenty days' duration.

In both of our cases 1 cc of alcohol was injected. Saltzstein<sup>5</sup> used this amount without complications. Analysis of the records of five cases from the medical wards of the Barnes Hospital discloses that 1 cc of absolute alcohol was injected into the lumbar sac without the development of any sphincteric disturbances. However, it is not difficult to understand how involvement of the lower sacral nerve roots occurred in our cases, especially in case 1, in which the site of injection was rather low. In both cases there was a persistent unilateral disturbance of both pain and touch sensation in the lower three or four sacral segments, although the zones of analgesia were wider than the zones of hypesthesia or anesthesia. Although this does not contradict absolutely the contention of the greater susceptibility of the pain fibers to alcohol fixation, nevertheless it is a warning that the myelinated fibers are not invulnerable to this technic. The use of the larger dose of alcohol may be responsible for these results.

We were impressed by the impermanence of the relief from pain and the persistence of sphincteric disturbances in both our cases. The sciatic pain syndrome in case 1 was relieved for five weeks, but its recurrence left the patient as disabled as ever. As our injections were made relatively low, the upper lumbar nerve roots must have been hardly involved at all, while the lower lumbar roots were temporarily blocked. The sacral roots, however, may be presumed to have been severely injured, requiring long periods for regeneration, if any is to occur. In case 2 the pain was due to a vascular disease of the legs, the pain mechanisms of which are vaguely understood. Perhaps the pathways of pain in this case were scarcely touched. It is well to recall that Dogliotti felt that pain from vascular disease of the extremities did not respond to this method of treatment. Stern, however, has reported favorable results, but in each case he made the injection between the twelfth dorsal and the first lumbar vertebra.

Vesical disturbances are well known symptoms of cauda equina lesions. According to Allen,<sup>6</sup> 50 per cent of all caudal tumors not involving the conus medullaris are accompanied by both bladder and bowel disturbances at some time, while only 34 per cent of his series of cases escaped sphincteric disturbances. Bladder symptoms in hemicaudal lesions may be transient, but with the early appearance and persistence of incontinence one is to suspect a conus lesion.

Curling,<sup>7</sup> Shattock,<sup>8</sup> Smith and Engel,<sup>9</sup> Barrington<sup>10</sup> and Creevy<sup>11</sup> emphasized the importance of intact bladder sensation in the maintenance of normal function. Since the sensory roots of the first to the fourth sacral nerves carry the afferent fibers from the bladder, the hemicaudal nature of the lesions in our cases, since they affected the bladder, is not contradicted by the apparent bilateral fifth sacral root involvement. Spiller<sup>12</sup> described the occurrence of permanent sphinc-

teric disturbances in a case of hemicaudal injury. The anatomic conditions in his case closely approximate those in our own. Whether the tip of the conus medullaris was injured by the alcohol we are not prepared to say.

#### CONCLUSIONS

1 Bowel and bladder disturbances followed lumbosacral subarachnoid injections for the relief of intractable pain in two cases.

2 In both cases, loss of pain and touch sensation in the lower sacral segments occurred unilaterally, with the exception of the last segment, which was bilaterally involved.

3 Only temporary relief from pain followed the treatment.

## THE TREND OF DIABETES MELLITUS IN NEW YORK CITY

STATISTICS FROM BELLEVUE HOSPITAL  
1911 TO 1935

ARTHUR MARTIN TIBER, MD

Assistant Visiting Physician and Physician in Charge of the Diabetes  
Clinic, Fourth Medical Division, Bellevue Hospital, Assistant  
Visiting Physician, Sea View Hospital

NEW YORK

A survey of the diabetes records from Jan 1, 1911, to Jan 1, 1935 was made at Bellevue Hospital, the largest general charity hospital in the city of New York. All cases in which the diagnosis of diabetes mellitus could be substantiated by the history or laboratory observations were included in the study, although this diagnosis may have been of secondary importance. The twenty-four year period was divided into four smaller periods of six years each: 1911-1916, 1917-1922, 1923-1928 and 1929-1934. Since the routine use of insulin was begun in Bellevue Hospital in February 1923, a comparison may be made of the incidence of diabetes and the effectiveness of the therapy employed during two preinsulin periods, and an early and a late Banting—that is, insulin—period.

#### FREQUENCY OF DIABETES

Table 1 shows for each of the four six-year periods the total number of general admissions and of diabetes admissions, the number of diabetic patients per thousand general admissions, the number of diabetic patients admitted for the first time, and the number of treated diabetic patients. The general hospital admissions increased 44.6 per cent between 1911-1916 and 1929-1934, whereas the diabetes admissions increased 395 per cent. This disproportionate rise of diabetes cases is also shown by the increase of the frequency of the disease from 2.8 per thousand general admissions in 1911-1916 to 9.7 in 1929-1934. The 246.4 per cent rise in the frequency of the disease is probably due to the discovery of new cases as there is an associated increase of 309.2 per cent in the first admissions for diabetes.

From the Fourth Medical Division, Bellevue Hospital, Dr. Charles H. Nammal, director.

Presented as part of the New York Diabetes Association exhibit at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 10-14, 1935.

Appreciation is hereby expressed to the directors of the various divisions of Bellevue Hospital for placing their records at my disposal and to Dr. H. O. McEntal and C. F. Bolduan and to Mr. G. J. Drolet of the New York Tuberculosis Association for their invaluable advice.

<sup>5</sup> Saltzstein H. C. Intraspinal (Subarachnoid) Injection of Absolute Alcohol. *N. Y. M. J.* 103: 242 (July 28) 1934.

<sup>6</sup> Allen J. M. Tumors Involving the Cauda Equina. *J. Neurol. & Psychopath.* 11: 111 (Oct.) 1930.

<sup>8</sup> Shattock S. C. Is There an Idiopathic Dilatation of the Urinary Bladder. *Proc. Roy. Soc. Med. (Sect. Path.)* 2: 88, 1908.

<sup>9</sup> Smith C. K. and Engel I. P. Neurogenic Vesical Dysfunction in Children. *J. Urol.* 28: 675 (Dec.) 1922.

<sup>10</sup> Barrington J. J. quoted by Creevy.<sup>11</sup>

<sup>11</sup> Creevy C. D. Neurogenic Vesical Dysfunction. *Arch. Neurol. & Psychiat.* 34: 277 (Oct.) 1935.

<sup>12</sup> Spiller W. G. Congenital and Acquired Lncure is from Spinal Lesion. *Am. J. M. Sc.* 151: 469 (April) 1916.

Lemann,<sup>1</sup> reporting from the New Orleans Charity Hospital, showed that there were 12 diabetic per thousand general admissions for 1909-1919 and 3 per thousand for 1921-1926, an increase of 150 per cent. The rates at Bellevue Hospital for approximately similar periods were 3.2 and 7.3 per thousand respectively, an increase of 128 per cent. Thus the frequency of diabetes in two large charity hospitals in widely separated sections of the country increased at nearly the same rate, although their initial levels were different.

#### READMISSION OF DIABETIC PATIENTS

The percentage of diabetes readmissions in 1911-1916 was 8.4, and in 1917-1922 it was 7.9, but after the introduction and use of insulin the percentage of readmissions increased to 13.9 in 1923-1928 and 19.2 in 1929-1934 (table 2). It is significant that not one of the patients treated for diabetes in the period 1911-1916 was readmitted in 1917-1922. Of those treated in 1917-1922, only thirty,<sup>2</sup> or 3.1 per cent, were readmitted during the early Banting period 1923-1928, whereas 182, or 9.8 per cent, of those treated in 1923-1928 were readmitted during the later Banting period, 1929-1934.

Hence it is evident from this record of readmissions that the life span of the diabetic patient has been prolonged by the use of insulin.

#### DIABETES CASE FATALITY

The case fatality rate is a statistical expression of the ratio of the number of deaths to the total number of treated cases and therefore may be used as an index of the effectiveness of treatment.

In tabulating the frequency of diabetes, all cases were included regardless of any other associated diagnoses, therefore it is logical that the same procedure should be followed in computing the case fatality rate. For this reason every fatal case was charged to diabetes, although diabetes may not have been the cause of death.

The total number of treated diabetic patients, the total number of fatal cases and the number of deaths per hundred treated cases (the case fatality rate) for

TABLE 1—Frequency of Diabetes in Bellevue Hospital

	Total General Hospital Admissions	Total Diabetes Admissions	Diabetes Admissions per 1 000 General Hospital Admissions	First Diabetes Hospital Admissions (New Cases)	Treated Diabetic Patients
1911-1916	253 406	714	2.8	634	634
1917-1922	255 096	109	4.2	975	975
1923-1928	296 377	2 164	7.3	1 854	1 864
1929-1934	366 444	3 535	9.7	2 676	2 858
Total	1 171 323	7 472		6 139	6 311

each six-year period, are shown in table 3. The fatality rate per hundred diabetic patients in 1911-1916 was 29.1, in 1917-1922 it was 24.3, in 1923-1928 it was 21.1 and in 1929-1934 it was 17.5. A comparison of these rates shows that the reduction between 1911-1916 and 1917-1922 was 16.5 per cent between 1917-1922 and 1923-1928 it was 13.2 per cent, and between 1923-1928 and 1929-1934 it was 17.1 per cent. Thus the downward trend of the diabetes case fatality rate began before the introduction of insulin, and the rate of reduction was somewhat curtailed in the early Banting period. However, in the later Banting period the rate

of reduction was accelerated, owing probably to the more effective use of insulin.

Hajek<sup>3</sup> reported the diabetes case fatality rate at St. Luke's Hospital in New York as 19 per hundred for the two-year period 1920-1921 and 11.6 for the eight-year period 1923-1930, a decrease of 38.9 per cent. Fitz and Murphy<sup>4</sup> showed that the average annual case fatality rate at the Peter Bent Brigham Hospital in Boston was 9 per hundred for 1913-1922 and Flynn,<sup>5</sup> reporting from the same hospital, showed that the rate was 7 per hundred for the period 1923-1933, a decrease of 22.2 per cent. For approximately the same periods, the diabetes case fatality rates at Bellevue

TABLE 2—Readmission of Diabetic Patients into Bellevue Hospital

	Total Diabetes Admissions	Treated Diabetic Patients	Readmissions		Readmissions First Admissions Preced.
			Number	Per Cent	
1911-1916	714	634	60	8.4	634
1917-1922	1 090	975	84	7.9	975
1923-1928	2 164	1 864	300	13.9	1 854
1929-1934	3 535	2 858	617	19.2	2 616

Hospital were 26.2 for 1911-1922 and 18.9 for 1923-1934, a decrease of 28 per cent. Although the diabetes case fatality rate in Bellevue Hospital is higher than that reported from other hospitals, the rate of reduction in this large charity hospital since the use of insulin compares favorably with that found in private institutions.

#### DIABETES AS A CAUSE OF DEATH

In this study, deaths occurring in patients with diabetes were tabulated as diabetes deaths. The diabetes mortality statistics from Bellevue Hospital may be compared with those of the entire city of New York, as the method of classification in use in the New York City Department of Health is quite similar, except that the diagnoses of certain important infectious diseases, such as pulmonary tuberculosis, typhoid and syphilis as well as cancer and occupational poisonings and violent deaths take precedence over diabetes.

The total number of deaths from all causes, the number of deaths charged to diabetes, and the percentage of deaths from diabetes in the total number of deaths from all causes, as found in Bellevue Hospital and reported for the entire city of New York,<sup>6</sup> are shown in table 4. The rise in the number of diabetes deaths per hundred total deaths in Bellevue Hospital from 0.95 in 1911-1916 to 2.1 in 1929-1934, an increase of 121 per cent, and from 1.26 to 2.63, or 108.7 per cent in the entire city of New York, indicates that there has been a relatively greater increase in diabetes deaths as compared to the total deaths, and that the rate of increase was practically the same in Bellevue Hospital and in New York City.

It has been suggested that there is an upward trend of deaths from diabetes because of the greater total number of diabetic patients in the entire population owing to more careful and efficient diagnoses and to the longer life span made possible in this disease.

2 The patients were admitted for the first time in 1921 or 1922.

through the use of insulin.<sup>7</sup> The present survey supports this hypothesis. The number of deaths from diabetes in Bellevue Hospital increased from 190 in 1911-1916 to 499 in 1929-1934, or 162.6 per cent, whereas the number of diabetic patients in the hospital increased from 654 to 2,858 or 337 per cent. In other words, the number of deaths increased with the number of diabetic patients, but the rate of increase was much lower.

#### ESTIMATED FREQUENCY OF DIABETES IN NEW YORK CITY

Diabetes not being a reportable disease, the only accurate method for estimating its frequency is to examine thoroughly a large representative group of the population and apply the results to the community as a whole. This method, being impracticable, it has been necessary to base estimates on data obtained from sickness surveys, health department mortality reports, and life insurance and health group examinations. However, sickness survey and mortality statistics reveal only the number of known sick and dead diabetic patients, thus no clue as to the number of well or unrecognized cases is obtained whereas life insurance company and health group statistics disclose the situation in the adult population (mostly male) of the higher economic and social groups. Hence these groups of statistics are not representative of the entire community and it is therefore necessary to find data that are more representative and base an estimate on them.

In table 4 it will be noted that the ratio of deaths from diabetes to total deaths in 1911-1916 was 1.3 times greater in New York City than in Bellevue Hospital, 1.3 in 1917-1922, 1.1 in 1923-1928, and 1.3 in 1929-1934. Since this relationship remained practically constant for four consecutive six-year periods, during which the number of deaths from diabetes increased at a greater rate than deaths from all other causes, it seems reasonable to assume that the change of the diabetes situation in Bellevue Hospital reflects the trend in the entire city. Consequently it is of the utmost importance to examine the Bellevue diabetes statistics and determine their value, as a basis for estimating the frequency of the disease in New York City.

TABLE 3—*Diabetes Case Fatality Rate in Bellevue Hospital*

	Treated Dia- betic Patients	Diabetes Deaths	Fatality Rate per Cent
1911-1916	654	190	29.1
1917-1922	975	236	24.3
1923-1928	1,864	394	21.1
1929-1934	2,858	499	17.5
Totals	6,351	1,319	

The limitations inherent in hospital morbidity and mortality statistics as a basis for estimating the number of diabetic patients in any community are acknowledged. Bellevue, however, is a general charity hospital of 2,200 beds admitting acute cases, with more than 60,000 annual admissions and an age distribution quite similar to that of the entire city population. Approximately 23 per cent of its discharged diabetic patients were unaware of their condition before admission,<sup>8</sup> and a large number of known diabetic patients were admitted and treated for conditions other than diabetes, furthermore the majority of the admissions are from

the lower economic and social groups, which, it has been shown,<sup>9</sup> have a lower percentage of diabetic patients.

It appears then, that the Bellevue Hospital diabetes morbidity and mortality statistics combined with the mortality statistics of the entire city of New York may be the basis for estimating, with a fair degree of accuracy, the maximum frequency of diabetes in the entire city. Thus the frequency of diabetes in the

TABLE 4—*Diabetes as a Cause of Death*

	Bellevue Hospital			New York City		
	Total Deaths from All Causes	Deaths Charged to Diabetes	Per Cent of Deaths in Total Deaths from All Causes	Total Deaths from All Causes	Deaths Charged to Diabetes	Per Cent of Deaths in Total Deaths from All Causes
1911-1916	19,942	190	0.95	451,150	5,700	1.26
1917-1922	20,964	236	1.13	458,325	6,762	1.48
1923-1928	22,133	394	1.78	437,171	8,450	1.94
1929-1934	23,752	499	2.10	435,117	11,934	2.63

general population, during each of the four six-year periods, may be estimated by substituting the known values in the following ratio:

$$\frac{\text{Number diabetic per 1,000 population A}}{\text{Number diabetes deaths per 100 deaths from all causes B}} = \frac{\text{Number diabetes admissions per 1,000 general admissions C}}{\text{Number diabetes deaths per 100 deaths from all causes D}}$$

With this formula the frequency of diabetes in the entire city of New York was estimated to be about 3.7 per thousand of population in 1911-1916, 5.5 in 1917-1922, 8.0 in 1923-1928 and 12.2 in 1929-1934.

It must be emphasized that these estimates are based on a survey of completely examined individuals of all ages, many of whom were wholly unaware of their condition until after admission into the hospital.<sup>8</sup> Hence they indicate the frequency of the total diabetes cases, diagnosed and as yet undiagnosed. On the other hand, most estimates previously reported in the literature were based on statistics of individuals cognizant of their condition and therefore are indicative only of the recognized cases of diabetes.

On the basis of their recent analysis of the available data on the incidence of diabetes, Joslin, Dublin and Marks<sup>9</sup> estimated the frequency of known diabetic patients in the entire United States as between 2.5 and 3 per thousand of population. However, they pointed out that diabetes is more prevalent in the Northeastern states—probably 4 per thousand of population, as was found in Massachusetts.<sup>10</sup> Since, as these authors further pointed out, the disease is more frequently encountered in urban areas than in rural ones, the incidence of diagnosed cases of diabetes would thus be between 4 and 5 per thousand of population in New York City.

Since the frequency of all diabetic patients diagnosed and as yet undiagnosed, averaged, according to the study here presented, 12.2 per thousand during the period 1929-1934, and the frequency of the diagnosed cases was between 4 and 5 per thousand, the frequency of unrecognized cases of diabetes may be estimated as between 7.2 and 8.2 per thousand. Thus from one half to two thirds of all diabetic persons in the city of New York are unaware of their condition. Evidence in

course and prognosis,<sup>12</sup> it is extremely important that this large group of unrecognized diabetic persons should be accorded proper medical supervision.

#### ESTIMATED DIABETES CASE FATALITY RATE IN NEW YORK CITY

The case fatality rate during each of the four six-year periods was computed from the estimated total number of diabetes cases and the reported deaths. The estimated diabetes case fatality rate for the entire city of New York fell from 5 in 1911-1916 to 3.6 in 1917-1922, to 2.8 in 1923-1928 and to 2.3 in 1929-1934 (table 6).

The decline in the case fatality rate from 4.3 in the preinsulin period of 1911-1922 to 2.55 in the Banting period of 1923-1934 reveals the effectiveness of modern diabetes treatment. In the face of this 40.7 per cent drop in the diabetes case fatality rate since the introduction and use of insulin, the skeptical observer may ask "Why has the crude diabetes death rate increased from 19.3 in 1911-1922 to 25.0 in 1923-1934?"

The crude diabetes death rate is the ratio of the total number of diabetes deaths, taken as a unit, to the general population.<sup>13</sup> Consequently, any factor that tends to raise the number of diabetes deaths contributes to an increase in its death rate, whereas a decrease will be caused by a fall in the case fatality rate and/or an increase in the general population. Since this survey shows that the total number of diabetic patients increased 177.2 per cent from 1911-1922 to 1923-1934 while the fatality rate fell 40.7 per cent and the general population increased 26.1 per cent, it is evident that the 29.5 per cent increase in the diabetes death rate only reflects the greater increase in the total number of cases of diabetes.

#### SUMMARY

1 The frequency of diabetes in Bellevue Hospital rose from 2.8 per thousand general admissions in 1911-1916 to 9.7 in 1929-1934, an increase of over 246 per cent.

2 The diabetes first admissions (new cases) increased nearly 310 per cent between 1911-1916 and 1929-1934.

3 The diabetes readmissions increased from 8.4 per cent in 1911-1916 to 19.2 per cent in 1929-1934.

4 Not one of the patients treated in 1911-1916 was readmitted in 1917-1922, but 9.8 per cent of the patients treated in 1923-1928 were readmitted in 1929-1934.

5 The percentage of deaths among diabetic patients (case fatality rate) in Bellevue Hospital fell from 29.1 in 1911-1916 to 17.5 in 1929-1934, a decrease of 40 per cent.

6 The number of diabetes deaths per hundred deaths from all causes in Bellevue Hospital increased from 0.95 in 1911-1916 to 2.1 in 1929-1934, or 121 per cent, whereas in the city of New York as a whole it increased from 1.26 to 2.63, or 109 per cent.

7 The frequency of diabetes in New York was estimated as 3.7 per thousand of population in 1911-1916, 5.5 in 1917-1922, 8.0 in 1923-1928 and 12.2 in 1929-1934.

8 The total number of diabetic persons in New York City during 1929-1934 was estimated as nearly 90,000 annually. It is believed that from one half to two thirds of these individuals are unaware of their condition.

9 The diabetes case fatality rate in New York City was estimated as 5 per hundred in 1911-1916, 3.6 in 1917-1922, 2.8 in 1923-1928 and 2.3 in 1929-1934. Since the introduction of insulin, the average yearly case fatality rate fell 40.7 per cent.

#### CONCLUSIONS

1 The frequency of diabetes mellitus in Bellevue Hospital has been increasing over a period of twenty-four years.

2 The life span of the diabetic patient has been definitely prolonged by the use of insulin.

TABLE 6—Diabetes Fatality and Death Rate in New York City

	Average Yearly Population	Frequency of Diabetes per 1 000 Population*	Average Yearly Diabetic Patients*	Average Yearly Diabetes Deaths†	Crude Diabetes Death Rate per 100 000	Diabetes Case Fatality Rate per Cent

\* Estimated  
† Official records

3 The downward trend of the diabetes case fatality rate began before the introduction of insulin but has been accelerated in the later insulin period.

4 The number of diabetes deaths increases with the number of diabetic patients, but the rate of increase is much lower.

5 There is a relatively greater increase of diabetes deaths as compared to the total deaths, and the rate of increase is practically the same in Bellevue Hospital and in the city of New York.

6 There are facts which indicate that Bellevue Hospital reflects the trend of diabetes in the entire city of New York.

EFFECT OF GONADOTROPIC EXTRACT  
OF THE PITUITARY IN  
CRYPTORCHIDISMAUGUST A WERNER, MD  
DOUGLAS KELLING MD  
DOROTHY ELLERSIECK, MD

AND

GEORGE A JOHNS MD  
ST LOUIS

Cryptorchidism is a congenital failure of descent of one or of both testicles in the male. The position of these glands may be, first in the peritoneal cavity, secondly, in the inguinal canals, and thirdly, a migratory type in which the testicles alternate between the lower inguinal canals and just outside the external inguinal rings. In the last type the testicles may descend into the upper part of the scrotum when the patient is relaxed, but any manipulation such as palpation causes their withdrawal into the canals.

NECESSITY FOR PRESENCE OF THE TESTES IN  
THE SCROTUM

It is known that the testes will not develop normally if they are not in the scrotum. Moore<sup>5</sup> proved the thermostatic value of the scrotum for normal function of the testes. He demonstrated that the germinal cells take on an irregular appearance and that the seminiferous tubules are irregular throughout if they are allowed to remain in the peritoneal cavity or high up in the inguinal canals. He also proved that when the testes are caused to assume a normal position in the scrotum the germinal epithelial cells of the tubules rearrange themselves in a normal manner and spermatogenesis occurs.

The testes normally descend into the scrotum shortly before birth. It has been said that if the testes do not descend within the first twelve months after birth they will not descend. This is not literally true, for occasionally they do descend as late as from the 15th to the 18th year. However one cannot allow a child to take such a risk. The sooner the cryptorchid condition

Gonadotropic principle derived from the anterior pituitary. This was supplied by Parke Davis & Co. All treatments started Sept. 30, 1935, with the exception of case 17 in which treatments were started October 26.

Etiology for failure of testicular descent may be divided into (1) obstructive conditions and (2) endocrine disorders. The obstructive factors are well known. That the anterior pituitary (gonadotropic) hormone is necessary for gonadal development has been conclusively proved.

Aschheim and Zondek<sup>1</sup> found both an estrogenic and a gonadotropic substance in the urine of pregnant women. For a while it was thought that this extract from the urine was identical with the anterior pituitary gonad-stimulating hormone, but this has been disproved by the work of Evans<sup>2</sup>, Collip and his co-workers,<sup>3</sup> Fevold and Hirsch<sup>4</sup> and others.

is recognized and corrected, the better it will be for the patient.

## TREATMENT OF UNDESCENDED TESTES

Until quite recently the treatment of undescended testes has been operative with variable results and more or less danger to the patient.

There have been more than forty different operations described in the literature for alleviation of this condition.

That surgical measures should be used only as a last resort to place the testicles in the scrotum has been proved by the successful induction of descent of these organs by the use of anterior pituitary-like extracts from pregnancy urine and a gonadotropic extract derived from the anterior pituitary gland which was used in this experiment.

Schiapero<sup>6</sup> in 1930 reported the treatment in thirteen cases of cryptorchidism with pregnancy urine extract with improvement in all cases. Engle hastened the

Klinische Studien über die Wirkung des Hypophyseenvorderlappens auf den männlichen Genitalapparat. *Ztschr. f. klin. Med.* 114: 610 1930.

growth of testes in immature rats and monkeys.<sup>7</sup> Brosius<sup>8</sup> reported descent of the testes in six cases and partial descent in two following the injection of gonadotropic substance from pregnancy urine. Brosius and Schaefer<sup>9</sup> produced spermatogenesis in a case presenting bilateral testicular atrophy following orchitis as a complication of mumps by the use of gonadotropic substance from the urine of pregnancy. The question remains in this instance as to whether the spermatogenesis was due to the latter substance or was a result of stimulation of the anterior pituitary to secrete gonadotropic hormone. Since then many instances of the successful treatment of cryptorchidism by the use of the various preparations of pregnancy urine extract have been reported.

regions, the sides being alternated each time. Every day or every other day 1 or 2 cc was injected, depending on which group the subject was in.

The table shows that both testicles descended into the scrotum in nine out of twelve boys within fifteen days after the onset of the injections. The remaining three boys required twenty-six, twenty-nine and thirty-three days.

The testicles in case 14, which descended into the scrotum on the twenty-third and the twenty-sixth day, alternated in position between the lower inguinal canals and the scrotum at different times since their descent and as yet have not remained descended permanently. Since they have been in the scrotum, which is evidence of no obstruction to their descent, it can be reasonably

Appearance before and after injections of gonadotropic extract of pituitary in eleven cases of cryptorchidism

#### TREATMENT OF CRYPTORCHIDISM WITH ANTERIOR PITUITARY GONADOTROPIC EXTRACT

It was interesting to know what effect the anterior pituitary gonadotropic extract would have on human cryptorchidism. A group of seventeen cryptorchid boys ranging in age from 5 to 13 years, as shown in the accompanying table, were treated with an extract derived from the anterior pituitary gland, standardized to contain 10 rat units of gonadotropic principle per cubic centimeter.

The boys were arranged according to age from the youngest to the oldest and gonadotropic hormone was administered intramuscularly in the upper gluteal

expected that they will finally remain descended at some not far distant date.

At the end of forty-nine days the dosage was changed so that each boy received 2 cc of anterior pituitary gonadotropic extract daily for a period of six weeks, regardless of whether the testes had descended or not. This was done to determine what effect the increased dosage would have on the development of the descended testes and whether it would cause descent of the testes in the boys who had had failure of descent.

There was some development of the testes after their descent. In most instances they were firm, but increase in size was not beyond that normal for the age of the individual. Increased dosage did not cause descent of the testes in five boys of this group who had failure of descent with smaller dosages, which indicates that probably these five boys have anatomic anomalies of development or obstruction which will require surgical procedures to place the testes in the scrotum.

9. Brosius, W. L. and Schaefer, R. L. Spermatogenesis Following Therapy with the Gonad Stimulating Extract from the Urine of Pregnancy. *J. A. M. A.* 101: 1227 (Oct. 14) 1933.

## CONCLUSIONS

1 Anterior pituitary gonadotropic extract is effective in causing descent of the testes in many cryptorchid boys

2 These results indicate that, before operative procedure is considered to correct cryptorchidism, anterior pituitary gonadotropic extract or anterior pituitary-like substance should be administered for approximately thirty days

3 If the testes do not descend into the scrotum after the administration of these hormone extracts, surgical procedures are justified

INDIRECT FRACTURE OF THE RIB  
IN PULMONARY TUBERCULOSIS

ERIC C RICHARDSON, MD

RAY BROOK, N Y

In a series of 1,903 tuberculous patients admitted to the sanatorium during the past five years, there were twenty individuals in whom a fracture of one or more ribs occurred as a result of muscular violence associated with coughing. There was one instance among 1,194 incipient cases (0.08 per cent), twelve among 601 moderately advanced (2 per cent) and seven among 108 far advanced (6.5 per cent). Ten additional cases were discovered in our outpatient department, making a total of thirty. In no instance was there a history of direct trauma and this factor may be reasonably excluded at least in ten of the patients who were confined to bed at the time the fracture occurred.

Fig 1 (case 1)—Roentgenographic appearance of chest showing fracture of the sixth rib on the right side

The incidence of fractures in this series leads me to agree with the view expressed by Stimson<sup>1</sup> some fifty years ago: "Fractures of one or more ribs are not infrequently caused by violent coughing," a statement to which in 1905 he added the significant phrase "especially in the consumptive." However, from a review of the literature one would conclude that the condition is rare. Graves<sup>2</sup> reported the first instance of indirect fracture of the rib in 1833, yet Wahl<sup>3</sup> in a comprehensive survey of the literature in 1926 found only sixty-six cases and since that time only a few others have been added. In the cases recorded in the literature the accident occurred occasionally in healthy individuals but usually in patients with pulmonary disease notably tuberculosis. Aside from coughing the

fracture was ascribed to muscular efforts during parturition, vomiting, sneezing, straining at stool, and lifting heavy objects.

The present paper reports the occurrence of fractures of the ribs during the course of pulmonary disease in thirty patients, comprising twenty-three women and seven men between the ages of 18 and 47. Twenty-four were suffering from pulmonary tuberculosis, three from silicosis complicated by tuberculosis and the remaining three from chronic bronchitis. In the cases observed, the fractures occurred in one or several of the ribs from the fifth to the eleventh inclusive. In no instance were fractures of the upper four ribs found. The fractures were single in seventeen instances and multiple in thirteen, unilateral in twenty-six instances and bilateral in four. The highest number encountered in any one patient was four, the result probably of a series of accidents, although it is not unlikely that more than one rib may be fractured simultaneously by muscular violence. The majority of the fractures occurred at approximately the junction of the anterior and middle thirds of the rib. Pain, although not severe, was an almost constant symptom and like the characteristic pain of pleurisy was aggravated on inspiration. The nature and location of the pain and the absence with few exceptions, of any displacement of the fragments on physical or radiographic examination usually led to the erroneous diagnosis of pleurisy. However this mistake in diagnosis was subsequently corrected by the study of the x-ray film taken a few weeks later, which disclosed the shadow cast by the callous formation at the site of the fracture. Once the location of the fracture was known, a review of the x-ray films taken when the pain first occurred frequently revealed a delicate linear shadow denoting the line of cleavage of the rib.

Fig 2 (case 1)—4 sectional enlargement of figure 1, B six months later showing complete union

The following two brief clinical histories illustrate the significance and course of fracture of the ribs occurring as a result of muscular violence in pulmonary tuberculosis.

Miss A, a pale thin febrile patient with advanced pulmonary tuberculosis and a severe productive cough complained of a

dull, aching pain in the axilla on the right side, aggravated on inspiration and relieved on expiration. Although there was no evidence of pleurisy except the location and characteristic nature of the pain, the diagnosis of pleurisy seemed justified in the presence of pulmonary tuberculosis and the absence of any other condition that would adequately explain the cause of the pain. Three weeks after the onset of the pain, a chest roent-

Fig 4 (case 2) —Sectional enlargement

genogram revealed a shadow at the junction of the anterior and middle thirds of the sixth rib, cast unmistakably by callous formation (fig 1 and fig 2 A). A chest film six months later showed that the callus had been completely absorbed leaving no evidence of the preexisting fracture (fig 2 B).

Miss B, with advanced pulmonary tuberculosis and a severe productive cough, had inspiratory pain in the left axilla. Pleurisy was diagnosed because of the character of the pain. A chest film a month later revealed a shadow cast by callous formation at the junction of the anterior and middle thirds of the seventh rib. After almost three years the inspiratory pain recurred in the left axilla and by the x-rays a fracture of the sixth rib in the axillary line was discovered (figs 3 and 4). The patient

died ten months later. At necropsy, the seventh rib at the site of the fracture presented a pseudarthrosis; the more recent fracture of the sixth rib, a sound callus (fig 5).

#### COMMENT

In view of the clinical histories, direct trauma may be reasonably excluded as the cause of the fractures in the patients included in the present study. The site of election of the fractures at the junction of the anterior and middle thirds of the ribs below the fourth, predominantly the sixth and seventh, suggests that the muscles involved are the serratus magnus and its antagonists, the external oblique, the rectus abdominus and the diaphragm.

In the cases observed there are certain contributory factors of possible significance. In the thirty instances reported in this paper, it is noteworthy that the occurrence of fractures bears a definite relationship to the stage of the tuberculous disease, the incidence being ten times greater in the advanced than in the incipient stage.

Fig 5 (case 2) —Roentgenographic appearance of excised sixth and seventh ribs

The higher incidence in patients with advanced tuberculosis may be attributed not only to the greater severity and frequency of the cough but also to an undue softening of the ribs noted by Smith<sup>4</sup> in a number of tuberculous

subjects coming to necropsy in the later stage of the disease. The incidence of the fractures was more than three times higher in women than in men, owing possibly to the comparative frailness of the ribs in women. The ages of the patients in this group ranged between 18 and 47 but since aged patients are not

treated at the sanatorium, no correlation can be established between incidence and age. In the cases cited it appears that infection plays no part in the causation of the fractures. Thus no relationship was found to exist between the site of fracture and the underlying disease. The callus as a rule was absorbed rapidly and completely, and in the two cases coming to necropsy the site of the fractures showed no evidence of infection. Consequently, it seems justifiable to assume that the fractures were brought about by muscular violence during the act of coughing. In tuberculous patients the location and the character of the pain associated with fracture of the ribs suggests the diagnosis of a complicating pleurisy in the absence of a history of direct trauma, and in those instances in which displacement of the fragments is not evident on physical and roentgenographic examination. The differential diagnosis generally cannot be established until later roentgenograms reveal the shadow of callous formation at the point of fracture.

Errors in differential diagnosis between an indirect fracture of the rib and pleurisy, based on our experience, would adequately explain the paucity of cases cited in the literature. The ribs are fractured more frequently than are the other bones of the body by muscular violence. The accident is not uncommon and occurs "especially in the consumptive," as stated by Stimson many years ago.

## HYPERNEPHROID CARCINOMA OF THE KIDNEY

WITH A TUMOR-THROMBUS FILLING THE INTERIOR VENA CAVA AND RIGHT HEART CAVITIES  
REPORT OF CASE

LEWIS W. WOODRUFF, M.D.  
AND  
VICTOR LEVINE, M.D.  
JOLIET, ILL.

Hypernephroid carcinoma of the kidney, more frequently than any other tumor, may spread into the inferior vena cava by direct extension of a tumor thrombus, may fill this vessel almost completely and in rare instances may penetrate the cavities of the right atrium and ventricle. In the most recent review, Polayes and Taft<sup>1</sup> found eleven cases in which such a tumor-thrombus of renal origin had invaded the heart in this manner, and they added a case of their own. Of these twelve cases, five presented the tumor thrombus extending into both atrium and ventricle, while in the remaining cases the atrium alone was involved. Most of these cases have been characterized clinically by slow, insidious onset with edema of the lower extremities, hematuria, enlarged liver, jaundice, and ascites in the late stage. The case reported here is of interest because of the large size of the tumor thrombus in the right ventricle and the absence of some of the clinical signs that are usually present.

#### REPORT OF CASE

J. K., a man aged 42, a farmer, was admitted, Nov. 1, 1934, in a state of collapse. Since the development of a cold four months previously he had complained of gradually increasing weakness and quick exhaustion, with dyspnea and palpitation.

From St. Joseph's Hospital  
I. Polayes, S. H. and Taft, H. Case of Hypernephroma with  
Tumor Thrombosis of Vena Cava and Heart. *Am. J. Path.* 7: 6170  
(Jan.) 1931.

and a slight cough. Jaundice had been present for several weeks and had increased in the past few days. He had lost 4 pounds (18 Kg) up to October 17, at which time he had been examined in a physician's office. The essential observations at that time were a temperature of 100 F, a palpable but not tender right kidney, only slightly increased hilar shadows as shown in roentgenograms of the chest, hemoglobin,

with a few 1 to 2 mm blood clots. These cavities had a direct connection with the branches of the renal veins which were also filled by partly softened light yellow-gray to purple-gray masses. These masses continued into the right renal vein and inferior vena cava. The inferior vena cava was blocked by a firm light yellow-gray to light purple gray mass, which extended for 4 cm below the opening of the renal veins up to the opening in the right auricle and occluded the openings of the hepatic veins.

The heart was distended and softened and weighed about 350 Gm. When the right side was opened it was found that the firm thrombus in the inferior vena cava extended as a cylindric mass that completely filled the atrium and the tricuspid orifice (fig 1). The mass was 5 cm in diameter and extended for a distance of 5 cm into the ventricle. On its tip was a tail 3 cm long and 1.5 cm in diameter. This thrombus-like mass was slightly adherent to the auricular surface of the tricuspid valve.

Microscopic examination disclosed that the large mass in the upper pole of the right kidney was composed of a solid mass of large polygonal cells with clear ample cytoplasm and deep staining anaplastic nuclei. Large areas were completely necrotic. The thrombus like mass in the right ventricle was composed of irregular cords of cells, similar to those seen in the mass in the kidney intermingled with fibrin (fig 2). The nodules in the lung were composed of groups of cells similar to those in the mass in the kidney.

Fig 1—T tumor thrombus filling right atrium, tricuspid orifice and extending into right ventricle. About one third natural size.

70 per cent with 3,600,000 red blood cells and 14,200 white blood cells. Urinalysis showed albumin one plus, a trace of bile and a few white and red blood cells in clumps and a negative Kahn reaction of the blood. Two days before admission into the hospital a loud systolic murmur was audible over the lower part of the sternum.

Examination was difficult because of the patient's extreme weakness. There was a marked jaundice of the skin and sclerae. The state of nutrition was good but there appeared to be considerable pallor. The heart tones were barely audible, the pulse was palpable but very weak. No rales or rhonchi on percussion were noted in the chest. The abdomen was moderately distended with the liver edge palpable two finger-breadths below the costal border. The kidneys and spleen were not palpable. Edema of the lower extremities or of the scrotum was not present. No blood could be obtained from the veins and only sufficient from the finger for a hemoglobin determination which was 50 per cent and a differential count which showed neutrophils 82 per cent, lymphocytes 12 per cent, monocytes 3 per cent, and eosinophils and basophils each 1 per cent. Urinalysis showed albumin 2 plus, bile 1 plus, several coarse granular casts and from 100 to 150 red blood cells per high power field. A transfusion of 500 cc of citrated blood was given but the patient died sixteen hours after admission. The only diagnosis suggested was carcinoma of the liver or biliary tract.

Postmortem examination was done by Dr. L. J. Wilhelm. The body was rather well nourished. The skin was markedly jaundiced. The abdomen contained about 1500 cc. of a clear straw-colored fluid. The lungs were everywhere studded with innumerable firm spherical nodules from 1 to 2 mm in diameter which were slightly raised above the external and cut surfaces. They varied from light gray to purple gray.

The right kidney was 18 by 9 by 8 cm. Its upper pole was replaced by a yellow-gray to purple-gray irregular mass 6 cm in diameter. The central portion was solidly light yellow. Throughout the parenchyma of the kidney, especially in the lower half, there were numerous cavities from 5 to 10 mm in diameter, partly filled with semiliquid yellow-gray material

Fig 2—Tumor thrombus showing tumor cells (T) intermingled with fibrin (F). Hematoxylin-eosin stain,  $\times 450$ .

The anatomic diagnosis was hypernephroid carcinoma of the upper pole of the right kidney with marked necrosis in the center of the tumor, multiple metastases to both lungs, extension of the carcinoma into the renal veins with the formation of a tumor thrombus, extension of the tumor-thrombus into the inferior vena cava, right atrium and right ventricle with obstruction of the hepatic veins and tricuspid orifice, icterus, gravis, slight ascites.

## COMMENT

Simpson<sup>2</sup> in 1924 also reviewed the literature on tumor-thrombus of the inferior vena cava. He found that 50 per cent of tumor-thrombi in this location were due to extension from a kidney, 20 per cent of testicular origin, 10 per cent following primary carcinoma of the liver and 9 per cent secondary to an adrenal tumor. Simpson found that in half of the cases of this type due to kidney tumors the tumor-thrombus extended into the heart. He also discussed the difficulty of making the diagnosis of this condition during life, pointing out that, even in instances in which it was necessary to ligate the inferior vena cava, the ill effects are usually transient and consist of a temporary edema of the lower extremities and an inconstant phlebectasia of the superficial collateral vessels.

The possibility of making a correct clinical diagnosis of obstruction of the inferior vena cava is therefore rather slight. Edema of the lower extremities and scrotum, ascites, dilatation of collateral veins, hematuria, jaundice and enlarged liver are the most frequent symptoms reported in the cases of obstruction following kidney tumor. The early subjective symptoms in our patient were increasing weakness, cough and dyspnea. In addition, a moderate anemia and a slight hematuria were also present. The early examination disclosed a palpable right kidney. Later a definite heart murmur, which was loud, systolic and located over the sternum, and a palpable liver also were noted. Slight ascites also developed terminally. Edema of the lower extremities and scrotum and dilatation of the superficial veins were never present, and their absence made it practically impossible to make a correct diagnosis before death. The probability is that the obstruction developed gradually and that the collateral circulation had sufficient time to compensate, thus causing no edema. In several of the cases quoted by Polayes and Tift,<sup>1</sup> edema was absent or transient.

The correct diagnosis in this type of case might be made, however, by the use of circulation time tests. Katz<sup>3</sup> has done this in one case using calcium bromide and determining the time required to develop a sensation of heat. He found that the normal circulation time from the foot was from seventeen to nineteen seconds. In the case in which there was obstruction of the inferior vena cava the circulation time was seventy seconds.

Other substances that have been used in determining circulation time were sodium dehydrocholate (decholin sodium) used by Winternitz, Deutsch and Brull,<sup>4</sup> and by Tarr, Oppenheimer and Sager,<sup>5</sup> which gives a bitter taste, saccharin, used by Fishberg, Hitzig and King,<sup>6</sup> which gives a sweet taste, and ether, used by Hitzig,<sup>7</sup> which gives an odor of ether. Allen and Barker<sup>8</sup> used injections of colloidal thorium dioxide, 25 per cent and de Takats<sup>9</sup> has used injections of skiodan to

outline veins on roentgen examination. None of these investigators tried their methods in obstruction of the inferior vena cava, but one or all of the methods might be used, especially the ether method of Hitzig, which may be used on an unconscious or a noncooperative patient.

## SUMMARY

A case of tumor-thrombus of the inferior vena cava arising from a hypernephroid carcinoma of the kidney and extending into the right atrium and ventricle, was not diagnosed during life, largely because of the absence of edema of the lower extremities. Circulation time tests might make a correct diagnosis possible in this type of case.

THE CARDIOVASCULAR STATE IN  
THYROTOXICOSIS

CHAUNCEY C MAHER, MD

AND

W WALTER SITTLER, MD

CHICAGO

Our purpose in this paper is to review the historical concept of the cardiovascular state in thyrotoxicosis, compare it with current points of view and present the status of the heart in 180 cases of thyrotoxicosis in modern terms.

Caleb Hillier Parry<sup>1</sup> in 1825 reported a case of exophthalmic goiter and rheumatic infection. The patient eventually died of congestive heart failure with out record of autopsy. Subsequently, he reported five other cases describing thyrotoxicosis with organic heart disease in at least two of them.

Graves<sup>2</sup> in 1835 again wrote of this disease, reporting three cases. The nervous symptoms, tachycardia, exophthalmos and palpitation were well described. In these case reports there was no evidence favoring organic or structural cardiac disease.

Basedow<sup>3</sup> next wrote of the goiter syndrome in 1840. His first patient was a woman with exophthalmic goiter complicated by acute articular rheumatism, malaria and two pregnancies. She was treated with iodine and digitalis. The second patient also had acute articular rheumatism and congestive heart failure with edema and with exophthalmic goiter. The third case was also exophthalmic goiter, which the author states presented a "carditis" or "aortitis." A fourth case of exophthalmos was described in which iodine was used by intunction. Basedow felt that during pregnancies improvement was noted in two of the cases.

Stokes<sup>4</sup> in 1854 wrote of goiter and discussed Parry's and Graves' case reports. He mentioned two of Parry's cases, saying "the thyroid swelling evidently followed a long existing cardiac disease." He concludes his discourse with a series of conclusions, the last of which is "that the essence of the disease appears to consist in a functional disturbance of the heart, which may be followed by organic change."

Trousseau<sup>5</sup> in 1856 wrote as follows: "I must add that valvular disease was present in some of Stokes'

cases, although he already saw that this was not the rule and he therefore described separately exophthalmic cachexia complicated by organic disease of the heart when treating of the disease. This clinical division should, I think, be retained, because, although exophthalmic goiter is not in my opinion, attended with dilatation of the cavities or alteration of the valves of the heart yet such lesions may coexist with it and may perhaps have been instrumental in bringing it on.

The patient's previous history and the presence of signs indicating organic lesions will enable the practitioner to ascribe each disease its proper share in the production of the cardiac condition." He further states that, in his opinion, hypertrophy does not result from exophthalmic goiter but a state of enlargement may develop, which he compares to the change occurring in the heart in pregnancy.

Fig 1—Left axis deviation in hypertensive vascular disease

In the century following Parry's original description, innumerable reports have been written on the subject of the cardiac status in thyrotoxicosis, and the subject still remains a very controversial problem.

The present varied concept of this question is typified by the data presented at the meeting of the American Heart Association held in New Orleans May 12, 1932, when a symposium was given on thyroid disease. The papers presented at this meeting came from divergent geographic sources in the United States and mainly

Fig 2—Right axis deviation in cor pulmonale

from internists interested in the study of heart disease rather than surgeons to whom the profession is indebted for a great number of reports on the subject of disease of the thyroid. It is of interest to note that there are two schools of opinion concerning the effect of thyroid disease on the heart. One group apparently believes that the thyroid has no effect on the cardiovascular system except to increase the metabolic activity while

the other is inclined to believe that the thyrotoxic disease causes myocardial damage, cardiac hypertrophy and change in the weight of the heart at autopsy and produces various clinical cardiac manifestations. In

Fig 3—Prolonged auriculoventricular conduction. First degree heart block in acute rheumatic carditis

some of the reports mention is made that thyrotoxicosis and structural heart disease coexist in the same patient.

Weller and his associates,<sup>6</sup> in reporting the histopathological changes of the heart in thyroid disease, say "Morphological study of thirty-five patients with exophthalmic goiter showed, with but few exceptions, no gross or microscopical changes not equally represented in a carefully matched control series." They quote several authors whose observations are in accord with

Fig 4—Incomplete left bundle branch block and complete auriculoventricular dissociation in acute rheumatic carditis

their own and a number of other observers including Wilson,<sup>7</sup> Fabr,<sup>8</sup> Ceelen,<sup>9</sup> and Kerr and Rusk,<sup>10</sup> who have demonstrated definite histopathologic lesions.

Rake and McEachern<sup>11</sup> reported that "many authors testify to the fact that when congestive heart failure appears in hyperthyroidism there is usually some other organic factor, rheumatic carditis, syphilis or the like, which tends to lower the cardiac reserve."

Burnett and Durbin<sup>12</sup> made a study of 148 cases of toxic goiter in the Colorado area. They found that

46 per cent of their patients either were "unimproved or had doubtful improvement after operation" Six of their patients are listed as having rheumatic carditis They write "We found definite electrocardiographic evidence of myocardial damage in addition to the disturbances in rhythm in a sufficient number of cases to warrant the conclusion that myocardial damage does occur in toxic goiter"

Lev and Hamburger<sup>17</sup> reported a study on angina pectoris in hyperthyroidism They say "We do not feel that angina pectoris in hyperthyroidism represents a separate entity due to any specific effects of the thyroid gland but rather that in these hearts there is already some underlying groundwork for the occurrence of anginal heart pains in the presence of hyperthyroidism"

Fig. 5—Rheumatic mitral stenosis as shown in a 2 meter roentgen study

Fig. 6—Hypertensive heart with left ventricular hypertrophy as shown in a 2 meter roentgen study

Jones, Seabrook and Menne<sup>13</sup> reported a series of goiter cases in the Pacific Northwest from the standpoint of the heart and thyrotoxic disease They say "The presence of a related cardiac syphilis, a rheumatic heart lesion or a cardiovascular hypertensive disease may influence the occurrence of fibrillation and failure, but such diseases mask rather than clarify the question as to the cause of the peculiar toxic type of heart which most clinicians of experience are agreed are not duplicated by other toxic agents"

Andrus<sup>14</sup> of Baltimore presented a series of 200 cases of hyperthyroidism He stated that other preexisting factors such as hypertension, arteriosclerosis and rarely syphilis, increased the incidence of congestive heart failure

Read<sup>15</sup> in California reported on the cardiac status following thyroidectomy He stated that inherent cardiac valvular disease may be hastened in its development by added work placed on the heart in thyrotoxicosis He also wrote "In summary, it may be said that these patients who, from the duration and intensity of their thyroid disease, might be expected to show the most characteristic and extreme cardiac damage are singularly free from evidence thereof although they average 45 years of age"

Kepler and Barnes<sup>16</sup> of Rochester, Minn., studied a series of 178 fatal cases of hyperthyroidism, of which 49 per cent were found to present structural heart disease

Other representatives of this assembly were Yater,<sup>18</sup> Lerman and Means,<sup>19</sup> and Menne and his associates.<sup>20</sup> Barker and his co-workers<sup>21</sup> reported a 15 per cent incidence of auricular fibrillation in thyrotoxicosis Anderson<sup>2</sup> of Cleveland reported an incidence of from 6 to 9 per cent

A somewhat different point of view of thyrotoxic-cardiac disease has been taken by Eggleston<sup>23</sup> in his recent report of patients with thyrotoxicosis Four classifications were made

- 1 Thyrotoxicosis with structurally normal heart
- 2 Thyrotoxicosis with rheumatic heart disease
- 3 Thyrotoxicosis with arteriosclerosis or hypertensive heart disease
- 4 "Masked" hyperthyroidism

Lahey,<sup>24</sup> who with his associates has been interested in this problem, makes the following statement as a result of their studies

Additional evidence that there is no such thing as a true thyroid heart is the fact that one does not see cardiac failure associated with intense degrees of hyperthyroidism even up to states which result fatally, provided there is no associated

Fig. 7—Syphilitic aortic regurgitation Aortic dilatation and left ventricular hypertrophy

Fig. 8—Cor pulmonale due to syphilitic pulmonary arteritis

cardiac damage We have seen a number of young people die of acute hyperthyroidism and yet at no time in these patients with undamaged hearts were there evidences of cardiac failure

Further evidence that there is no true thyroid heart is available in the fact that even when patients have had hyperthyroidism over a long period of time if they are relieved of their hyperthyroidism their cardiac capacity is then just as great as it was before their hyperthyroidism appeared. In other words, there is no permanent cardiac damage done even though intense hyperthyroidism has existed over a considerable period of time.

Many other reports might be quoted from the literature, similar in character to those cited concerning the cardiac status in hyperthyroidism.

The criteria for diagnosis of thyroid heart due to adenoma with hyperthyroidism or exophthalmic goiter, as listed by the American Heart Association,<sup>25</sup> are as follows: "1. Evidence of hyperthyroidism and enlargement of the heart. 2. Evidence of hyperthyroidism associated with abnormal cardiac function such as paroxysmal or permanent auricular fibrillation."

A study of the cardiac status of any individual with hyperthyroidism must obviously include the effect of the thyrotoxicosis on the heart and blood vessels and due consideration of all other etiologic factors that may affect the cardiovascular system. Thyrotoxicosis may act subsequently or coincidentally with any other known etiologic factor.

A committee of the American Heart Association has published a monograph<sup>26</sup> describing the various etiologic factors and the pathologic changes in the muscle, valves, pericardium and blood vessels. Several studies of these etiologic factors causing heart trouble show that rheumatic infection, hypertension, arteriosclerosis, syphilis, thyrotoxicosis, pulmonary disease, congenital causes, toxins and bacterial entities are the cause of most cardiovascular disease.<sup>26</sup> Each of these etiologic factors produces distinct structural or anatomic deformities that are recognizable with sufficient clinical study, and objective proof may usually be obtained through the laboratory with fluoroscopic and x-ray studies and with the electrocardiogram.

In the past the general term "organic heart disease," embracing several specific disease entities, and the popular designation "chronic myocarditis," have been indiscriminately employed both clinically and pathologically.

In the years 1926 to 1935 inclusive we have had the opportunity of studying 180 cases in which thyrotoxicosis was an etiologic factor of the cardiac problem. These cases were encountered in a private and consultation cardiac practice in a general male medical ward (No. 25) in the Cook County Hospital, and in the heart clinic at Northwestern University Medical School in the following proportions: private practice 111 cases, Northwestern Cardiac Clinic thirty-four cases, and Cook County Hospital thirty-five cases.

The method of study of these cases included a routine history, physical examination, electrocardiograms, 2-meter heart films and fluoroscopy, and routine laboratory examinations of the blood and urine and a Wassermann test as a minimum requirement. Numerous basal metabolic studies were made on each patient with sufficient clinical observation to establish correctly the

diagnosis of thyrotoxicosis. Cardiac diagnosis was established on the composite evidence obtained from the history, the physical changes and the laboratory data, particularly from the 2-meter x-ray film and the electrocardiograms. Many of the patients were studied by other physicians and we are indebted to them and to the institutions that have furnished us with their records and observations to complete our own studies.

We have found that a number of these patients have had coexisting organic heart disease such as rheumatic valvulitis, coronary disease, hypertension, cor pulmonale or syphilitic heart disease that has had a definite bearing on the clinical observations, operative risk and subsequent course of the patient.

A study of our data shows that these cases were divisible into three distinct groups: (1) thyrotoxicosis uncomplicated by structural heart disease (20.6 per cent), (2) thyrotoxicosis with organic heart disease (75.5 per cent), (3) neurocirculatory asthenia with possible thyrotoxicosis (3.8 per cent). The group with

Fig. 9—Relative incidence of the various types of heart disease complicated by thyrotoxicosis.

organic heart disease and thyrotoxicosis may be further classified into definite etiologic entities. The relative incidence of the various types of heart disease that have been found associated with thyrotoxicosis is shown in figure 9. The various types of complicating heart disease will be discussed separately in detail in later parts of this paper.

#### THYROTOXICOSIS UNCOMPLICATED BY ORGANIC HEART DISEASE

Thirty-seven patients were placed in the group of thyrotoxicosis uncomplicated by organic heart disease, representing 20.6 per cent of the total. Structural change in the cardiovascular system was not excluded in these individuals on a single criterion but on the composite negative evidence obtained from the history, physical examination and laboratory studies.

In this group of thirty-seven patients twelve (32.4 per cent) showed exophthalmos and twenty-five (67.7 per cent) had an adenomatous type of goiter. The age range was from 24 to 62 years with the majority (75 per cent) under 45. Practically all of them were residents of the Chicago area for most of their lives. Fifteen had had a thyroidectomy performed, three had been treated with x-rays and one with radium, and the remaining eighteen had had only medical management.

From a historical standpoint, the antecedent medical histories were comparatively negative. A history of

rheumatism, syphilis, hypertension or antecedent heart disease was elicited in none of the cases. A family history of apoplexy was present in only two cases, one patient had a childhood history of rheumatism and one patient had a history of an increase in blood pressure during a pregnancy.

Subjectively, the common cardiac symptom was palpitation and tachycardia. Symptoms of congestive failure such as cough, marked dyspnea, hemoptysis or swollen extremities, were absent. Anginal pain was not noted. Dyspnea was elicited as a symptom in only 25 per cent of these cases and was of minor degree.

From the standpoint of objective physical manifestations, the majority were essentially negative with reference to increase in size of the percussion dullness, cardiac murmurs, arrhythmias or peripheral sclerosis. Murmurs were encountered in less than 12 per cent of the entire group and these were located over the base of the heart and classified as functional.

The blood pressure records showed wide variations and a great lack of stability in the systolic readings, varying from 115 to 148 depending on the emotional status of the patient at the time the record was obtained. In the hospital environment at bed rest, consistently normal readings were secured. The diastolic readings showed a variation ranging from 58 to 85.

The orthodiagrams or 2-meter film studies never revealed cardiac hypertrophy, and the transverse width of the heart never measured more than half the width of the chest. The position and shape of the heart image varied with the physique of the individual patient.

The electrocardiograms were essentially negative. Very minor conduction deformities of the ventricular complex were encountered in less than 14 per cent of the total. Extrasystoles were infrequent. Heart block was absent in any degree. Auricular fibrillation was encountered in only one case.

Essentially, the diagnosis of the absence of structural heart disease was borne out by each phase of the cardiac examination and by the absence of subjective or objective evidence of cardiac failure.

#### HYPERTENSIVE GROUP

The criterion for the diagnosis of hypertensive vascular disease as defined by the American Heart Association<sup>25</sup> is "persistent hypertension with peripheral sclerosis and a characteristic hypertrophy of the left ventricle." The current concept of the course of hypertensive vascular disease has been described by Fishberg,<sup>27</sup> Christian<sup>28</sup> and Janeway.<sup>29</sup>

Patients with this problem pass through a period (usually measurable in years) of hypertension without symptoms. At the end stage in the majority of them congestive heart failure develops lasting from several months to a few years with death as the outcome. In a lesser number localized vascular lesions develop, frequently cerebral hemorrhage or thrombosis with that mode of death. In a few renal failure and uremia develop and death occurs in that manner. A variable number die of intercurrent complications of pneumonia, accident or other disease entities. Complications of arteriosclerosis, diabetes mellitus, urologic disease, obesity and emphysema are not uncommon.

Thyrototoxicosis and hypertensive vascular disease are syndromes that have certain symptoms and signs in common. Many of these similarities have been the subject of investigation, with considerable diversity of opinion concerning the relationship of the two disease entities. For example, Crile<sup>30</sup> states "It is quite conceivable that a relatively slight overstimulation of the vasomotor mechanisms from overactivity of the thyroid or from perverted secretion, if it persists over a long period of years, may lead to an elevation of the blood pressure or to permanent myocardial damage, which is manifested by auricular fibrillation, by paroxysmal tachycardia or in some instances by cardiac decompensation."

Fishberg<sup>27</sup> conversely states "It is not uncommon for patients with long-standing thyrototoxicosis but no true hypertension at first to develop hypertension when he or more often she, reaches middle life. However the hypertension in such individuals cannot be attributed directly to the thyrototoxicosis, for much more severe Graves' disease in the young, even though present for years does not produce elevation of the diastolic pressure."

From the standpoint of blood pressure in thyrototoxicosis, Plummer<sup>31</sup> in 1915 and Taussig<sup>32</sup> in 1916 pointed out an increase in the systolic blood pressure and also an increase in the pulse pressure. Fullerton and Harrop<sup>33</sup> disagree with this finding. Their reports show that, under basal conditions, neither the systolic pressure nor the pulse pressure is abnormal. Willis and Boothby<sup>34</sup> in 1923 divided thyrototoxicosis into two groups, the exophthalmic type and the adenomatous goiter with thyrototoxicosis. Their blood pressure studies in the latter group showed an increase in the diastolic pressure, implying this type of hyperthyroidism as a cause of hypertensive vascular disease.

The basal metabolic rate may be increased in hypertensive vascular disease and has been the subject of numerous studies such as those of Boothby and Sandiford<sup>35</sup> who found rates of from +15 per cent to -15 per cent in 89.4 per cent of 170 cases of hypertension. Riesman<sup>36</sup> in 1919 described cases of hypertension under the term of "nongoitrous thyrototoxic hypertension." Boas and Shapiro<sup>37</sup> in 1925 again studied the problem of metabolism in this type of patient. In a series of twenty-seven patients, ten showed rates above +15 per cent.

Hamburger<sup>38</sup> demonstrated that in congestive heart failure the basal metabolic rate may be elevated.

The question of cardiac enlargement and cardiac hypertrophy in thyroid disease has been a controversial subject. In the early period Stokes,<sup>4</sup> Graves and Trousseau<sup>5</sup> voiced their opinion based on examination of the heart by percussion. Today the argument is continued with the orthodiagram or the 2-meter plate, and the question remains in dispute.

29 Janeway T C A Clinical Study of Hypertensive Cardiovascular Disease Arch Int Med 12 750 (Dec) 1915

Simonds and Brandes<sup>39</sup> reviewed the status of this question in animal studies. They produced experimental hyperthyroidism in dogs and reported the development of cardiac hypertrophy.

Hurxthal<sup>40</sup> from clinical studies in 1930 reported "If hyperthyroidism causes cardiac enlargement or hypertrophy and dilatation it is slight." Hurxthal<sup>41</sup> in 1932 again reported "Slight to moderate degrees of ventricular hypertrophy were found in cases of long duration, but gross cardiac enlargement was usually associated with coincident cardiovascular disease."

Since these two syndromes present certain symptoms and signs in common the diagnosis of either may present difficulties, and the possibility of error is worthy of consideration. The clinical evaluation of patients in whom both these syndromes may be present is even more complicated. The differentiation of these entities is rendered less problematic if the patient is under observation over a protracted period of time, as for months or years, with repeated observation of the hypertension and vascular state and repeated study of the metabolism. Consideration of either as a syndrome rather than from isolated symptoms also lessens the frequency of error.

In fifty-five of our patients who were placed in this group we found sufficient evidence to justify the diagnosis of both hypertensive vascular disease and thyrotoxicosis. Citation of a few cases best describes this combination.

**CASE 1**—M. C., an Italian widow aged 56 died in 1934. Her family background was medically negative and her only childhood illness was scarlet fever. She married at the age of 18 and went through three pregnancies. No blood pressure records were obtainable of this period and no definite evidence could be secured concerning the duration of her hypertensive problem. She had an adenomatous goiter, of which she was unaware prior to 1932.

During 1932-1934 she presented the characteristic syndrome of hypertensive vascular disease complicated by a variable degree of congestive heart failure. The systolic pressure ranged between 180 and 220 and the diastolic level from 100 to 120. There was a moderate grade of peripheral sclerosis, aortic sclerosis and a hypertrophied left ventricle (2-meter plate). An electrocardiogram showed a left bundle branch block. The course was punctuated by repeated attacks of acute pulmonary edema. The basal metabolic rate level was observed to be within normal limits on repeated observations.

In June 1934 the patient was in an automobile accident resulting in a minor scalp injury. Within a month the clinical picture showed a dramatic change. A rapid weight loss of 25 pounds (11.3 Kg.) developed with extreme nervousness, emotionism, tremor, insomnia and intolerance to heat. The basal metabolic level rose to +50 per cent.

Surgical intervention and other management were refused and within twelve weeks of the onset of the thyrotoxic state she died during an attack of acute pulmonary edema.

There appeared to be reasonable evidence in this case to justify the onset of thyrotoxicosis superimposed on a hypertensive vascular problem.

**CASE 2**—L. C., a housewife died at 57 years. Her father and mother died of apoplexy. In childhood she had measles, diphtheria, scarlet fever and pertussis. She married at the age of 29 and was pregnant on one occasion but miscarried at three months.

In 1914 when she was 37 a laparotomy was performed for a pelvic infection complicated by pneumonia and she was an invalid for nine months. The blood pressure was within normal limits during this time. An increase in the blood pressure was

discovered after the operation but the exact date is not known. The systolic pressure varied from 150 to 170 and the diastolic from 90 to 100. Her course from 1914 to 1926 was asymptomatic with reference to the hypertension.

In 1926 a gastro-intestinal problem developed with diarrhea and loss of weight, without a definite diagnosis being established.

In 1928 cardiac symptoms became prominent with the onset of auricular fibrillation and congestive heart failure.

In 1929 she was discovered to have a substernal adenomatous goiter with a maximum basal metabolic rate of plus 45 per cent. She had a thyroidectomy in 1930. The auricular fibrillation remained after operation but cardiac compensation was readily secured and her course was uneventful for over a year.

In 1931 a cerebral thrombosis developed, which she survived with a mild residual spastic paraplegia.

During 1932 and 1933 she suffered from repeated attacks of renal stone and died with a complicating cerebral thrombosis, at the age of 57.

This patient appeared to have a hypertensive vascular disease of some years' duration with a superimposed thyrotoxicosis relieved by operation.

The life histories of the patients in this group vary in detail but are essentially similar.

The diagnosis of the hypertensive vascular syndrome was dependent on the composite evidence obtained in each case. This consisted essentially of the history, repeated blood pressure records, the cardiac physical changes, the peripheral vascular status, the x-ray screen, film studies and electrocardiograms.

In the group of fifty-five patients with a diagnosis of hypertensive vascular disease and thyrotoxicosis forty-one were women and fourteen were men. The age range was from 27 to 72 years, with 80 per cent of the patients between the ages of 40 and 65. Nine patients had an exophthalmic type of goiter and forty-six the adenomatous type. Twenty-six of the patients of this group were operated on and twenty-nine were not. Four sustained repeated operations for recurrence of thyrotoxicosis.

From a historical standpoint, 35 per cent of the cases presented a familial history of hypertensive vascular disease or its complications. Only 10 per cent of the group were able to give information concerning their former blood pressure records. One patient had a definite record concerning an acute and chronic nephritic problem one year prior to the onset of the thyrotoxicosis.

Symptomatically, this group of patients complained of a wide variety of symptoms. Thirty-two of the fifty-five patients showed cardiac symptoms of congestive heart failure including dyspnea, orthopnea, cough and edema of the ankles. Two of the group showed symptoms referable to cerebral vascular disorder and two were in the uremic group. Seventeen of the patients were in the asymptomatic period of their hypertensive vascular disease and were free of symptoms except for palpitation and tachycardia.

The conditions encountered in physical examination were characteristic of hypertensive vascular disease. All the patients in this group showed sclerosis of the peripheral vessels of varying grade manifested in the brachial or retinal arteries. Basal systolic murmurs with accentuated aortic closure were an almost constant finding. In the group showing congestive failure diminished heart tones were often present. Gallop rhythm during the period of thyrotoxicosis was encountered in one tenth of the patients. Accurate percussion of the cardiac width was seldom possible.

The blood pressure records were consistently high ranging from 170 to 260 systolic and from 90 to 150

<sup>39</sup> Simonds, J. P. and Brandes, W. W. The Size of the Heart in Experimental Hyperthyroidism. *Arch. Int. Med.* 17: 40 (April) 1919.

<sup>40</sup> Hurxthal, I. M., Menard, O. J. and Brandes, W. W. The Size of the Heart in Goiter. *Am. J. Med. Sci.* 140: 77 (Dec.) 1910.

<sup>41</sup> Menard, O. J. and Hurxthal, I. M. Cardiac Dilatation in Toxic Goiter. *Am. Heart J.* 13: 135 (Oct.) 1912.

diastolic. Occasionally in those patients with congestive heart failure with marked edema exceptionally low systolic readings were recorded. In one patient the systolic pressure during a period of congestive heart failure was found to be 110 and several months after thyroidectomy it reached a systolic level of 200.

In electrocardiographic studies, forty-one showed the characteristic left axis deviation of persistent hypertension. Twelve patients showed a normal axis deviation. Left bundle branch block was encountered in two cases and partial heart block with prolongation of the auriculoventricular conduction time to 0.28 second was encountered in one case. Seventy per cent of the curves showed conduction deformities of the ventricular complex, indicative of myocardial damage. Thirteen cases were in the auricular fibrillation group, one patient showed a persistent auricular flutter and one case was found to present a paroxysmal tachycardia of auriculoventricular nodal origin. One patient in this group showed moderate right axis deviation with conduction deformity of the ventricular complex. This patient had a marked emphysema and an associated pulmonary type of heart disease.

Fluoroscopic and roentgenographic studies (2-meter films) showed enlargement or hypertrophy of the left ventricle in all cases. In those patients with congestive heart failure the hypertrophy was most marked. Widening of the aortic shadow was present in more than 50 per cent of the cases.

Six patients in this group have suffered a cerebral thrombosis within two years following thyroidectomy. It is possible that this figure would be higher than this if all cases had been followed to date.

In summary, the fifty-five patients have been classified with the combination of thyrotoxicosis and hypertensive vascular disease manifested not only by elevation of the blood pressure but also by characteristic physical changes, electrocardiographic studies and x-ray studies. In 60 per cent of this hypertensive group the advent of congestive heart failure appeared to be a result of the superimposed thyrotoxicosis.

#### RHEUMATIC HEART DISEASE

Rheumatic heart disease is currently looked on as an infectious process with the Aschoff nodule as the pathologic unit, involving the valves, myocardium and pericardium. The valvular involvement is most often the mitral, and less commonly the aortic, but sometimes both valves are involved. The mechanical narrowing of the mitral orifice is productive of the left auricular and right ventricular hypertrophy with a characteristic x-ray image. Aortic stenosis is associated with left ventricular hypertrophy.

There is increasing evidence to prove that rheumatic heart disease is often a subacute low grade infection rather than a chronic healed process, as has been considered heretofore. Rothschild, Kugel and Gross,<sup>42</sup> in studying 161 autopsies in rheumatic heart disease, found evidence of active infection in 106 cases. There is also evidence which indicates that the "rheumatic" infection may affect almost any tissue of the body. This point of view places more stress on the infectious element in the myocardium and other viscera than on the mechanical defects of the valves. Rheumatic myocarditis may injure the conduction system, producing varying degrees of heart block.

The coexistence of thyrotoxicosis and rheumatic carditis is recorded in the early case reports of Parry,<sup>1</sup> Basedow,<sup>3</sup> Stokes<sup>4</sup> and Trousseau.<sup>5</sup> Numerous authors including Flint,<sup>43</sup> Paul,<sup>44</sup> Hayden,<sup>45</sup> Broadbent<sup>46</sup> and Fothergill,<sup>47</sup> through the succeeding years have referred to these reports but added no new information.

From a clinical standpoint many of the modern writers have entirely neglected this relationship. The subject has been discussed at some length by Llewellyn<sup>48</sup> who points out that "the incidence of mortality from acute and chronic rheumatism is markedly higher in districts where goiter is endemic." It is his opinion that arthritis may result from the hypothyroid state but he also notes the occurrence of rheumatic infection in hyperthyroidism.

In the pathologic studies one frequently finds references to the coexistence of the two entities, as those of Weller,<sup>6</sup> Lewis,<sup>49</sup> Kepler and Barnes<sup>16</sup>. Cabot,<sup>50</sup> however, reported a single case in 1929 of the coexistence of thyrotoxicosis and rheumatic heart disease as the only case of this type he had ever encountered in his wide experience in the autopsy room.

In our series the coexistence of rheumatic heart disease and thyrotoxicosis was encountered in forty-two cases, or 23.3 per cent of the total. A few characteristic cases best present the combination.

CASE 3—G. J., a single woman, aged 35, a housewife, had scarlet fever when she was 8 years of age, and was told during adolescence that she had a mitral stenosis. She had a large goiter, first noted when she was 13 years old. During youth and early adult life she was examined by several physicians corroborating the presence of the valvular lesion, and she was considered to have a nontoxic goiter. This was corroborated by normal metabolic studies.

At the age of 33 she became pregnant and was delivered uneventfully at term. Her metabolic rate during the pregnancy was plus 10 per cent and plus 12 per cent. During the first month post partum she lost 15 pounds (6.8 Kg.), became nervous and irritable, and tremor and tachycardia developed. The basal metabolic rate reached a maximum of plus 34 per cent. There was a presystolic-systolic murmur and thrill at the apex, a typical mitral heart on roentgen examination and a characteristic right axis deviation in the electrocardiogram. No break in compensation was observed.

The patient was successfully operated on (thyroidectomy) and pursued an uneventful postoperative course except for transient attack of paroxysmal auricular fibrillation successfully controlled with quinidine and digitalis. The patient gained 20 pounds (9 Kg.) and since the operation has been active without disability from the rheumatic mitral stenosis.

The coexistence of two diseases in this patient was quite distinct.

CASE 4—A youth, unmarried, aged 19 years, a laborer, entered the Cook County Hospital with a typical clinical picture of exophthalmic goiter of two months' duration. His antecedent cardiac history was negative except for an illness at the age of 12 years of several weeks' duration, attributed to "kidney inflammation."

A moderate grade pharyngitis protracted low grade temperature and increased tachycardia developed. Over a period of three months aortic stenosis developed and also a mitral

42 Rothschild M. A. Kugel M. A. and Gross L. Incidence and Significance of Active Infection in Cases of Rheumatic Cardiovascular Disease During the Various Age Periods Am. Heart J. 9 386 (June) 1934

lesion. The heart area on roentgen examination showed an increase in size and the right and left ventricles had become more prominent.

Dropped beats were discovered and electrocardiograms substantiated the clinical observation. The degree of block varied from a prolongation of the PR interval to complete auriculo-ventricular dissociation.

The coexistence of acute rheumatic carditis (valvulitis and myocarditis with heart block) and thyrotoxicosis in this patient presents a somewhat more serious type of the combination. Three other patients in the series presented similar pictures.

Of the forty-two patients in this series who were found to have rheumatic valvular disease complicated by thyrotoxicosis, women preponderated over men in a ratio of 29:13. Seventy-five per cent were under 45 years of age with an age range of from 20 to 65 years. Thirty-six cases were classified as thyroid adenomas and six were exophthalmic goiters. Twenty patients were operated on, four were treated by x-rays, and eighteen were not operated on.

A history of rheumatism, chorea or known valvular disease prior to the advent of thyrotoxicosis was obtained in 60 per cent of patients in this group.

From the standpoint of symptomatology seventeen patients, or approximately 40 per cent, presented complaints characteristic of congestive heart failure with marked dyspnea and gross edema. One patient's symptomatology was that of dry pericarditis with marked precordial pain. Seven patients of this group presented symptoms of active rheumatic fever.

The physical changes in this group of patients were dependent on the particular valvular lesion encountered. Seven presented changes of combined lesions of the aortic and mitral orifices. Thirty-four patients were classified as having uncomplicated mitral stenosis and one patient (aged 65) had a definite dry pericarditis with a friction rub and active joint involvement. The fluoroscopic and roentgenographic studies of these patients showed characteristic cardiac images dependent on the valvular lesion. Cardiac hypertrophy was most marked in those patients in whom congestive heart failure was a complicating factor.

In the electrocardiographic studies, right axis deviation of marked degree was present in only one sixth of the mitral cases. Auricular fibrillation was present in thirteen of the forty-two cases. Four patients were found to have variable degrees of heart block. Two patients were found to have transient complete auriculo-ventricular dissociation and one of these was further complicated by a transient left bundle branch block. Both of these patients showed dropped beats and prolongation of the conduction time. Two patients showed permanent prolongation of the auriculo-ventricular conduction time. Wedd<sup>51</sup> reported a case of complete heart block during an attack of acute rheumatic fever in a patient who had been operated on the same year for exophthalmic goiter. The electrocardiogram taken during the period of thyrotoxicosis was reported as normal and also the cardiac examination was reported as giving normal results. Davis and Smith<sup>52</sup> reported six cases of complete heart block in thyrotoxicosis complicated by acute infections not classified as rheumatic.

The blood pressure records were usually not of diagnostic importance.

In summary, forty-two cases were classified in the rheumatic valvular group with superimposed thyrotoxicosis. Sixty per cent were complicated by congestive heart failure precipitated by the thyrotoxicosis. The historical data, the characteristic murmurs and the x-ray studies were the pertinent factors in the diagnosis of the rheumatic heart disease.

#### ARTERIOSCLEROTIC GROUP

Arteriosclerotic heart disease implies coronary sclerosis locally, usually associated with generalized arteriosclerosis. Coronary thrombosis and myocardial infarction often complicate the process. Symptomatically, angina pectoris is a cardinal symptom. This type of heart disease usually occurs in the latter years of life. Levine<sup>53</sup> gives the average age in a series of 145 cases of coronary thrombosis as 57.8 years. Complicating disease entities of diabetes mellitus, prostatic hypertrophy and hypertension often are present.

Mora and Greene<sup>54</sup> reported a series of cases of thyrotoxicosis in older persons. They described the cardiac symptomatology and manifestations but did not classify the cases as to etiologic factors. Angina was not listed as a cardiac symptom in their study.

Lev and Hamburger<sup>55</sup> in 1928 reported six cases of angina pectoris and hyperthyroidism. One included an autopsy report with definite coronary disease.

Levine and Walker<sup>56</sup> in 1929 discussed the problem of so-called latent hyperthyroidism masked as heart disease, in association with angina pectoris. It was pointed out that in those with typical anginal attacks proper treatment of the latent hyperthyroidism resulted in a great reduction in the number of attacks, if not complete relief from symptoms.

White<sup>57</sup> points out that an extra demand on the coronary circulation in thyrotoxicosis may be sufficient to provoke angina pectoris in a patient with defective coronary arteries. Case 5 is characteristic in this group.

CASE 5—C. F., a widow aged 65 in childhood had had measles and a mild 'inflammatory rheumatism'. She had an infected finger amputated in adolescence. She was married at 20 and gave birth to eleven children. At the age of 55 she went through the menopause.

At the age of 56 the syndrome of thyrotoxicosis developed complicated with dyspnea, precordial distress and pain in the left arm on exertion. Attacks of cardiac irregularity developed which were found to be paroxysmal auricular fibrillation. She had a generalized arteriosclerosis marked in the radial and brachial vessels and manifest in the retinal arteries. The 2-meter plate showed sclerosis of the aorta. The electrocardiogram showed mild left axis deviation and mild conduction deformity of the ventricular complex.

At 57 she was successfully operated on. She regained her weight and the cardiac symptoms disappeared except for rare attacks of paroxysmal fibrillation.

From the age of 57 to her present age of 65 her medical problems have been concerned with a mild hydronephrosis and pyelitis with secondary anemia. On exertion during her periods of anemia she has mild anginal pain.

Of the twenty patients classified in this group twelve were women and eight were men. The age range was from 54 to 75. All but one were under 70.

<sup>52</sup> Davis, C. V. and Smith, H. I. Complete Heart Block in Hyperthyroidism Following Acute Infection. A Report of Six Cases with Necropsy Findings in One Case. Am. Heart J. 9, 81-89 (Oct.) 1933.

<sup>53</sup> Levine, Samuel. Coronary Thrombosis. Its Various Clinical Features. Baltimore, Williams & Wilkins Company, 1929.

<sup>54</sup> Mora, J. M. and Greene, F. I. Thyroidectomy for Thyrotoxicosis in Older People. Am. J. M. Sc. 181, 74 (Jan.) 1931.

<sup>55</sup> Lev, M. W. and Hamburger, W. W. The Association of Angina Pectoris and Hyperthyroidism. Am. Heart J. 3, 72 (Aug.) 1928.

<sup>56</sup> Levine, S. A. and Walker, G. L. New England J. Med. 201, 1021 (Nov. 21) 1929.

<sup>57</sup> White, Paul. Heart Disease. New York, Macmillan Company, 1922.

Nineteen had thyrotoxic adenomas and one had an exophthalmic goiter. Nine were operated on, two were treated by x-rays, eight were not operated on and one was treated with radium.

Symptomatically, angina was present in all twenty patients. Eight of the group manifested symptoms of congestive heart failure with gross edema.

The cardiac examinations in this group frequently showed diminished intensity of the heart tones, in six apical systolic murmurs were present. All this group showed well marked peripheral arteriosclerosis. In 50 per cent of the group there was a concomitant moderate grade hypertension. One patient had an inactive syphilis, two had moderate grades of emphysema. In the electrocardiographic studies, six showed auricular fibrillation and one had a permanent, complete auriculoventricular dissociation. All had some degree of conduction deformity of the ventricular complex. Three of the patients in this group are known to have died of acute coronary thrombosis and one, who had a coronary thrombosis, subsequently died of cerebral thrombosis.

In summary, twenty patients were classified in the arteriosclerosis group with the associated syndrome of thyrotoxicosis. The outstanding features were the age incidence in the latter decades of life, characteristic anginal pain and peripheral sclerosis. The electrocardiograms and the roentgenograms were helpful in diagnosis.

#### PULMONARY HEART DISEASE

Pulmonary heart disease has been described under a number of terms such as the emphysema heart,<sup>58</sup> pulmonary heart,<sup>59</sup> eccentric right ventricular hypertrophy,<sup>60</sup> pulmonary arteriosclerosis,<sup>61</sup> Ayerza's disease<sup>62</sup> and pulmonary hypertension.<sup>63</sup> Recently the term "cor pulmonale" has been introduced.

Essentially, the pathologic changes consist of right ventricular hypertrophy, pulmonary arteriosclerosis, and pathologic damage to the lung parenchyma or bony thorax usually associated with emphysema. Etiologically, these pathologic changes arise from chronic tuberculosis, asthma plus bronchial infection, chronic bronchiectasis, lung carcinoma, silicosis, deformities of the thorax following trauma, rachitis, poliomyelitis or Pott's disease. Symptomatically the patient presents the signs and symptoms of the primary lung problem plus cyanosis, tachycardia, polycythemia, right ventricular enlargement and eventually congestive heart failure as the right ventricle dilates.

The damage to the lung parenchyma or the deformity of the bony thorax diminishes the capacity of the oxygenating system. Right ventricular hypertrophy and hypertension in the pulmonary circuit result to meet this need.

We have encountered the combination of cor pulmonale and thyrotoxicosis in eleven cases. Case 6 is characteristic of this group and is presented with autopsy.

CASE 6—J. L., a laborer, died at the age of 46. The antecedent medical history was essentially negative except for a 'chronic bronchitis,' which had been present since childhood.

At the age of 45, nervousness, palpitation, fatigue, tachycardia and loss of weight developed, with a basal metabolic rate which reached a maximum of plus 75 per cent. During his period of hospitalization, enlargement of the liver, ascites and gross edema of the ankles developed.

The 2-meter heart plate showed right ventricular hypertrophy with marked increase of the connective tissue throughout the lung parenchyma and emphysema. The electrocardiogram presented marked right axis deviation with auricular fibrillation. He was refractory to iodine and died with a complicating problem of gastric hemorrhage.

Autopsy revealed a typical pulmonary type of heart with gross eccentric hypertrophy of the right ventricle. There was an associated pulmonary arteriosclerosis, bronchiectasis and emphysema of the lungs. The gastric hemorrhage was the result of superficial ulceration of the gastric mucosa.

CASE 7—M. S., a man, aged 41, came under observation in 1928 for a gastric hemorrhage. His medical history was essentially negative, and he stated that he had not had venereal infection. In 1929 the patient was again under observation with congestive heart failure, which was classified as syphilitic pulmonary arteritis (Ayerza's disease).

Comparison of the 2-meter heart plates showed a progressive increase in the size of the right side of the heart. The blood Wassermann reaction was positive. The electrocardiogram presented an increasing degree of right axis deviation.

During the period of 1931 to 1934 the patient was an inmate of an institution and under irregular antisyphilitic therapy. In 1935 nervousness, tachycardia, fatigue and loss of weight developed with mild exophthalmos and thyroid enlargement, with a basal metabolic rate of plus 40 per cent.

Eleven patients were classified in the group with pulmonary heart disease, of whom nine were men and two were women. The age range was from 41 to 67, with a majority between 45 and 60. Eight were classified as having adenomas with thyrotoxicosis, and three were of the exophthalmic type. Only two of this group were operated on and one was treated with x-rays. The remaining eight were not operated on. Nine of these patients presented symptoms of congestive heart failure with marked dyspnea and gross edema. The cardiac examination was essentially negative, with distant heart tones. Percussion did not give information of value. The essential finding common to all this group was the marked emphysema of the chest. Clubbing of the fingers was present in four of the eleven cases.

In the electrocardiographic tracings the characteristic right axis deviation was found in only three of the cases, and conduction deformity of the ventricular complex was present in ten of the eleven.

The x-ray studies were primarily of importance in studying the pathologic changes of the lungs. Two of the patients were classified as having chronic fibroid tuberculosis. Two were classified as asthmatic with an associated bronchitis. One had a syphilitic pulmonary disease and the remainder had bronchiectasis.

In summary, eleven patients were classified as having a pulmonary form of heart disease and associated thyrotoxicosis. The essential features of this type of heart disease include the primary lung changes, emphysema, few local cardiac disorders, and the x-ray evidence.

#### SYPHILITIC HEART DISEASE

Syphilitic heart disease pathologically consists of localized aortitis, diffuse aortitis with dilatation, and aneurysm or involvement of the aortic valves with regurgitation and left ventricular hypertrophy. Myocardial gummas rarely occur and syphilitic myocarditis

<sup>58</sup> Laennec, Rene. *Cultivation mediate*, ed. 2, 1826.

<sup>60</sup> Bertin, J. *Maladies du cœur*, Paris, 1824. Corvisart, J. N.

*The Heart and Great Vessels*, translated by Jacob Gates, Philadelphia, 1812.

<sup>61</sup> Poselt, A. in *Lubarch-Otertag*, *Ergebn. d. allg. Path.* 13: 298, 1909.

<sup>62</sup> Ayerza, L. *Maladie d'Ayerza*, *clercosa*, *secondine de l'arter pulmonaire* (cardioques noirs), *Semana med.* 1: 43 (Jan.) 1925.

<sup>63</sup> Moebowitz, Eli. *Hypertension of the Pulmonary Circulation*, *Am. J. M. Sc.* 1: 4: 388 (Sept.) 1927.

is a disputed entity. The coronary orifices may be narrowed in the syphilitic aortitis but not as a rule in the branches in the myocardium.

We have encountered seven cases of the combination of syphilitic heart disease and thyrotoxicosis.

CASE 8—Mrs H M, aged 48, a housewife American, was married at the age of 20 and had two miscarriages. Her husband died of heart disease of an undetermined type. Her second marriage was sterile.

In 1924 she was ill for a period of several months, with weight loss, palpitation, tachycardia and dyspnea, and was told by her physician that she had a goiter. At the end of this illness her cardiac symptoms disappeared and she regained her weight loss.

From 1924 to 1930 the course was comparatively uneventful. In 1930 she had a recurrence of cardiac symptoms and the advent of congestive heart failure. Nervousness, fatigue, tremor and weight loss again recurred and her basal metabolic rate reached a level of plus 45 per cent. From a cardiac standpoint the patient presented cardiac hypertrophy with a systolic-diastolic murmur at the base with congestive heart failure, liver enlargement and edema of the ankles. Fluoroscopic examination and an x-ray film showed diffuse aortic dilatation and cardiac hypertrophy. The Wassermann reaction was positive.

Compensation was secured and successful thyroidectomy was performed. The cardiac symptoms disappeared and the patient remained fully compensated for a period of two years, with limited physical activity.

CASE 9—A business man aged 39 had measles in childhood and no other known illnesses. He was married but had no offspring. At the age of 35 he gradually lost weight and became nervous and fatigued. Paroxysmal attacks of auricular fibrillation developed and were recorded electrocardiographically. The cardiac changes included a tachycardia, systolic basal murmur and a blood pressure of 130 systolic, 80 diastolic. The basal metabolic rate was plus 25 per cent, and the Wassermann reaction was positive.

The patient was successfully operated on and the thyrotoxic symptoms were abated and the paroxysmal fibrillation disappeared. Treatment for syphilis was instituted with irregular cooperation by the patient. Two years after operation palpitation, dyspnea and stenocardia on mild exertion developed. The aorta fluoroscopically and on the x-ray film showed diffuse dilatation. The Wassermann reaction was still positive and the basal metabolic rate was normal.

Netherton<sup>64</sup> reported sixty-two cases in which syphilis and goiter were associated. Seventy-two per cent of these patients had hyperthyroidism. The cardiovascular status of these patients was not clearly stated. An excellent bibliography of the subject is presented by this author.

Schulmann<sup>65</sup> reported three cases of thyrotoxicosis and syphilitic disease. The cardiac changes were not given in the first case. The second patient appeared to have aortic regurgitation. The third patient had syphilitic aortitis with dilatation. A number of cases of thyrotoxicosis and syphilis were reviewed but little information was given concerning the cardiovascular state. Several authors were quoted who presumed that syphilis was a cause of exophthalmic goiter.

Seven patients were found with thyrotoxicosis and associated syphilitic infection. Six of the seven showed definite syphilitic cardiovascular symptoms and one case was classified as potential heart disease with no demonstrable evidence of aortitis.

Five of the patients were women and two were men. The age range was from 20 to 55. Six of the patients had adenomas with thyrotoxicosis and one was of the

exophthalmic type. Only two of the group were operated on. Three patients presented symptoms of congestive heart failure and four were without symptoms.

Physical changes in this group were dependent on the type of syphilitic heart disease presented. One patient showed a characteristic aortic regurgitation with a dilated aorta, with a systolic-diastolic murmur at the base of the heart. The other five showed systolic basal murmurs with varying degrees of accentuation of the aortic closure. Two patients showed some degree of hypertension. One patient had an associated syphilis of the central nervous system.

In the electrocardiographic tracings one patient was shown to have developed paroxysmal auricular fibrillation. Left axis deviation was found in three patients and the axis deviation was normal in four. Conduction deformity of the ventricular complex was found in three of the seven. In only one patient of the group was the history of the primary lesion obtained.

In summary, seven patients were classified in the syphilitic group, six of whom were found to have definite cardiovascular involvement with thyrotoxicosis.

#### NEUROCIRCULATORY ASTHENIA

The effort syndrome, irritable heart, disordered action of the heart, soldiers' heart and neurocirculatory asthenia are diagnostic terms of functional cardiac disorders. Lewis's<sup>66</sup> monograph on this subject, as a result of cardiac problems arising during the World War, crystallized diagnostic concepts of this syndrome. Essentially this type of functional cardiac disorder consists of symptoms of "breathlessness on exertion, fatigue, exhaustion, precordial pain, palpitation, faintness, giddiness, tachycardia and unstable blood pressure." The term "effort syndrome" implies the poor cardiac response to exertion. Manifestations of psychoneurosis are often present. Evidence of organic heart disease is absent. Lewis<sup>66</sup> states "It has been suggested that the symptoms and signs in these patients are the result of excessive internal secretion of the thyroid gland. The onus of proof rests on those who put forward this hypothesis." He found palpable enlargement of the thyroid gland in only nineteen of 504 soldiers examined.

The similarity of this syndrome and the symptomatology of thyrotoxicosis is obvious. The patient with neurocirculatory asthenia may be mistakenly diagnosed as having thyrotoxicosis and undergo thyroidectomy. No doubt cases of thyrotoxicosis have been wrongly classified as effort syndrome. One must also consider the possibility of a combination of thyrotoxicosis and neurocirculatory asthenia in the same patient. We have encountered seven patients with neurocirculatory asthenia who have undergone thyroidectomy. Five were women and two were men. The age range was from 22 to 40. All were classified as having adenomatous goiters with thyrotoxicosis. These patients presented the usual syndrome of fatigue, palpitation, weakness and inability to withstand physical or emotional activity. Physical examination was essentially negative. Tachycardia was always present. No murmurs were present. Their blood pressure readings showed many variations even over short periods of time. The electrocardiographic tracings were all normal and the x-ray studies were negative. The basal meta-

bolic rates were secured with considerable difficulty. Repeated trials were usually necessary and apprehension of the patients often gave inaccurate tests, but normal readings after repeated efforts, were secured in all these patients.

We had the opportunity of studying three of these patients both before and after operation. In one of the three we recommended thyroidectomy and two were advised against it. In the patient in whom we advised operation, our subsequent studies have shown no remission of symptoms.

We do not feel that we have encountered a patient with the combination of neurocirculatory asthenia and thyrotoxicosis.

The four patients whom we have studied only after thyroidectomy reported no beneficial results of the operation.

Differential diagnosis of these two syndromes is usually difficult. There is no single criterion on which differentiation may be established. Our studies would indicate that thyrotoxicosis is not a factor in the production of the syndrome of neurocirculatory asthenia. It appears possible, however, that the two syndromes may coexist in the same individual.

Fig. 10—Incidence of the various etiologic factors with thyrotoxicosis producing auricular fibrillation.

#### SUBACUTE BACTERIAL ENDOCARDITIS

One case of subacute bacterial endocarditis with an older rheumatic valvulitis with thyrotoxicosis was encountered. The patient was a young woman with a mild mitral stenosis in whom a thyrotoxicosis with exophthalmos developed. Six months after the onset of the thyroid intoxication, following the extraction of an infected tooth, she showed marked aggravation of symptoms with elevation of temperature, splenic enlargement, petechiae and a positive blood culture of *Streptococcus viridans*. The course lasted twenty-one days. Autopsy was refused.

#### AURICULAR FIBRILLATION

Auricular fibrillation was encountered in forty-two cases, or 22 per cent. Anderson<sup>22</sup> quotes an incidence of from 6 to 9 per cent in his studies and Barker<sup>21</sup> gives an incidence of 15 per cent. In our series there is a higher percentage of nonsurgical cases than in either of these studies.

With one exception, all the cases in which auricular fibrillation was present were associated with organic disease. The frequency of the various types is demonstrated in figure 10. Hypertension, rheumatic disease and coronary sclerosis account for the majority of the cases.

In this group of forty-two patients, 38 per cent (sixteen) were men and 61 per cent (twenty-six) were women. The age range was from 34 to 72 years, with 75 per cent of the patients between 40 and 60. The average age was 52.4 years. Six cases were of the paroxysmal type and thirty-six were of the chronic type of auricular fibrillation. In one fourth of the patients who were operated on, fibrillation still continued postoperatively. Three had exophthalmic goiters and thirty-nine had the adenomatous type.

There did not appear to be any definite relationship between the degree of thyrotoxicosis and the occurrence of the auricular fibrillation. The exceptionally high basal metabolic rates were not always accompanied by the irregularity.

Congestive heart failure was present in the majority of cases (thirty-eight) and was absent in only four cases.

It was our judgment from the study of this group of patients that the basic cause for the auricular fibrillation was the structural heart disease and that the precipitating element was the thyrotoxicosis.

#### SUMMARY

In studying the effects of thyrotoxicosis on the cardiovascular system, one must duly consider the presence or absence of other causative agents that might affect the heart and blood vessels. If such an etiologic factor of heart disease is present or has been previously active, one must evaluate the cardiovascular changes in the light of both elements.

In this series of patients, etiologic factors of hypertension, rheumatic infection, arteriosclerosis, pulmonary disease, syphilis and *Streptococcus viridans* were found to have been coexistent with the thyrotoxicosis or pre-existent to the advent of the thyrotoxicosis.

The problem therefore was to ascribe to each factor its proper share in the production of the abnormal cardiovascular changes. Our method of solving this problem was predicated on the assumption that hypertension, rheumatic infection, arteriosclerosis, syphilis, pulmonary disease and *Streptococcus viridans* are each associated with reasonably consistent and characteristic pathologic changes in the heart and blood vessels. The effect of thyrotoxicosis, uncomplicated by these other etiologic factors on the cardiovascular system, afforded a comparative base for the complicated group. Evaluation of symptoms and signs before and after thyroidectomy was also an aid. The problem, however, of assigning each factor its proper share was not without difficulty, and possibilities of error are, of course, conceded.

In the group of patients with uncomplicated thyrotoxicosis, the subjective symptoms were limited to palpitation and rapid heart beat. Objectively there were no characteristic physical changes other than tachycardia and lability of blood pressure with emotional stress. (One exception was noted in the occurrence of a paroxysmal auricular fibrillation in a patient whom we classified as not having structural heart disease.)

In the group of patients with thyrotoxicosis and coexistent etiologic factors, added subjective complaints were present, such as dyspnea, orthopnea, cough, angina, stenocardia and hemoptysis. Objectively there were a variety of physical changes, such as murmurs, thrills, friction rub, gallop rhythm and arrhythmias. The cardiac images on the 2-meter films were of varied

shape and size. The diversity of these changes testified, in a measure, to a multiplicity of causative factors rather than the single element of thyrotoxicosis.

On analysis of each individual case the evidence was sufficient to classify the cases into groups of (a) hypertensive vascular disease, (b) rheumatic valvular disease, (c) arteriosclerotic coronary disease, (d) syphilitic cardiovascular disease, (e) cor pulmonale, and (f) thrombo-endocarditis. A few patients had more than one such factor to consider, such as combinations of arteriosclerosis and hypertension, pulmonary disease and arteriosclerosis, or syphilis and hypertension. In such cases classification was made on the basis of the predominant factor.

Congestive heart failure was not present in uncomplicated thyrotoxicosis. The presence of this phenomenon was associated with the coexistence of a structural lesion.

Physiologically, thyrotoxicosis appeared to act on the heart to increase its metabolic activity as it does on other organs. This was manifested primarily by tachycardia. Abnormal cardiac physiologic function, as determined clinically or demonstrated objectively by the electrocardiogram, such as heart block (all types) damage to ventricular conduction system and auricular fibrillation, appeared to be manifestations of the primary organic heart disease modified by the element of thyrotoxicosis.

The frequency of occurrence of uncomplicated thyrotoxicosis in this series is 20 per cent, and of thyrotoxicosis complicated by organic heart disease 75 per cent. It is possible that this does not present a true statistical picture of the problem, as two of the three sources of our material are a private practice of heart disease and a heart dispensary, where one might expect to find a high percentage of the combination of organic lesions and thyrotoxicosis. Further studies from a statistical standpoint are desirable from other sources such as a large surgical goiter clinic, or a general medical source. The general conclusions, however, regardless of the incidence would remain the same.

It is not within the scope of this paper to discuss fully the ramifications of the interrelationship of thyrotoxicosis and the various types of structural heart disease. In general, however, the effect of the thyrotoxicosis appeared to be that of a catalytic agent. The course of the organic heart disease progressed more rapidly when the thyrotoxicosis was active. The thyrotoxicosis brought to the surface latent cardiovascular lesions, which resumed their latency on the successful termination of the thyroid toxemia.

We wish to point out the desirability of considering the patient from two points of view: first the thyrotoxic aspect and, second, that of coexisting organic heart disease. Also we would stress the necessity of diagnostic studies along these lines. This implies exhaustive historical data, searching physical examination, and the full utilization of laboratory methods, particularly the roentgenographic and electrocardiographic methods.

#### CONCLUSION

It is our belief that the next step in the further reduction of surgical mortality and morbidity (since iodine has been demonstrated as successful in temporarily controlling the thyrotoxicosis) lies in the recognition and proper management of all associated pathologic changes, particularly in the cardiovascular system.

## TYPE SPECIFICITY IN PNEUMONIA AND PNEUMOCOCCIC INFECTIONS

### A PRELIMINARY REPORT

CORDULA KOHL, B.S.

AND

R. J. REITZEL, M.D.

SAN FRANCISCO

Clinical, bacteriologic and epidemiologic questions arise from the more exact differentiation of the old group IV pneumococcus into twenty-seven specific serologic groups. In view of the work of Cooper<sup>1</sup> on the separation of these newer types of pneumococci, a review of the incidence of pneumococcus types in various localities is in order. As there are no data available concerning type specificity of pneumococci found in pneumonia in a general hospital in this locality, it was thought worth while to present some of the results of a study that is being made at San Francisco Hospital, in the present paper the survey covers the period from December 1932 to December 1935. The incidence of types and the sources of pneumococci from infections other than pneumonia during this period have been included in the report.

During the first part of the study, the pneumococci were classified by use of serums of types I, II, III and VII, subgroup IIA was designated as such, the "unclassified" included all the pneumococci that failed to be grouped into these five types. Later in the study we became interested in learning how this group of "unclassified" pneumococci could be separated into the types as identified by Cooper. In order to complete the classification of the types serums of types I to XXXII inclusive were obtained in January 1934 from the department of health of New York City, through the cooperation of Georgia Cooper.

In this report we are chiefly interested in the bacteriologic aspect of lobar pneumonia in adult patients in the medical division of this hospital. Material was collected from other infections throughout the University of California Service of this hospital. We present our bacteriologic procedures, methods for typing and the results with a discussion of type classification including the figures for the incidence, mortality, bacteremia complications and the monthly distribution of each type specific pneumococcus that was isolated. We offer comparative figures from recent publications of similar investigations in other localities where serums from the same source as ours were used for type classification. Also data on a series of serum-treated cases have been included.

#### BACTERIOLOGIC PROCEDURES

**Blood Cultures**—Blood cultures were usually taken within twelve hours after admission of the patients, if no growth was found in forty-eight hours, cultures were repeated when clinically indicated. About 5 cc of blood was added directly to 100 cc of hormone-brain broth. Pour plates were made only when bac-

The authors acknowledge assistance from the George Williams Hooper Foundation for Medical Research during the early part of the work. The last twenty-seven months' work was assisted by a grant from the Christine B. and R. C. Fund.

<sup>1</sup> Cooper, Georgia, Edwards, Marquerite and Roentgen, Carolyn. The Separation of Types Among the Pneumococci. *Hitherto Called Group IV* and the Development of Therapeutic Antiserums for These Types. *J. Exp. Med.* 49:461-474 (March) 1929; *ibid.* 55:531-534 (April) 1932.

terial counts were desired. After four to twenty-four hours' incubation at 37 C., growth was found in the hormone-brain broth, from 0.3 to 0.5 cc was transferred to 5 cc of dextrose-veal-ascitic broth (50 per cent ascitic fluid) or to 5 cc of brain heart broth (Difco). This transplant usually had sufficient growth in from four to six hours to permit typing and the test for solubility in bile. The fermentation of inulin was determined, and the appearance of the growth on blood agar was noted. The original blood culture was centrifuged and often the supernatant fluid could be used for typing.

**Sputum**—About 1 cc of thick sputum was selected, washed several times in sterile saline solution, and emulsified, 3 or 4 drops was added to 5 cc of dextrose-veal-ascitic broth and incubated for from four to ten hours, the remainder was inoculated intraperitoneally into a white mouse. From five to eighteen hours later, the mouse was killed and the peritoneal exudate was removed, the heart was removed and cultures were

platinum loop, 4 mm in diameter, was used.) Clumping or flocculation appeared within a few moments, agitation accelerated the reaction.

**Test Tube Method**—This method was necessary when the diagnostic serum crossed with that of other strains. The serum was diluted as indicated on the serum bottle, equal parts of the diluted serum and the culture were used, usually 0.5 cc of each. The tubes were incubated or placed in a water bath at 56 C for from one to two hours, after which time the resulting agglutination was read.

**Neufeld Method**<sup>2</sup>—The sputum was placed in saline solution in a petri dish and small flecks were washed out. Very small amounts were picked up with a platinum loop and placed on cover glasses. To each bit of sputum, one loopful of diagnostic rabbit serum was added, followed immediately by a drop of Loeffler's methylene blue. Each cover glass was inverted over a petrolatum ring on a slide and the preparation was examined under the high dry or oil immersion lens of the microscope. Within two to thirty minutes the capsule of the pneumococcus would give a characteristic swollen appearance when in its homologous serum. In our experience, this is the most rapid method and is dependable. This method is also applicable to the growth in blood cultures and to pneumococci found in purulent exudates.

**Results of Typing**—Pneumococci that were isolated from blood cultures and from heart blood of mice following inoculation with sputum were considered most desirable for type classification of the pneumonia cases. Sputum cultures checked the mouse inoculations seventy out of seventy-three times, in nine cases they checked the positive observations in the blood culture when a mouse inoculation had been omitted.

Although type specific pneumococci may be isolated from the blood, sputum, nasopharynx or purulent exudate such as empyema fluid, the question arises as to whether the pneumonia patient without sputum (a small minority) and with a supposedly negative blood culture may be type specifically classified from the nasopharyngeal cultures. Nasopharyngeal cultures checked the mouse inoculations (sputum) sixty out of sixty-four times, in sixteen cases in which the blood culture was positive, the type of pneumococcus isolated from the nasopharyngeal swab checked with that in the blood culture.

The type of the organism isolated from purulent complications (table 7) checked with the type from the blood or from the sputum except in one case in which a slightly reacting type VI organism was found in the sputum late in the pneumonia, and subsequently the empyema fluid showed a type I organism.

In nine cases, cultures were taken from the affected lobes at the postmortem examinations when the necropsies were performed within two hours after death. All these typings corroborated the results from the sputum by mouse inoculations or from the blood cultures.

From a few cases, which are not included in the tables a single specimen of sputum yielded two distinct types of pneumococci following the mouse inoculation. In one instance the exudate of the mouse gave a type II and the heart culture gave a type I organism. Similar results have been reported by Heffron and

taken. About 0.5 cc of the peritoneal exudate was added to 5 cc of broth, the remainder was centrifuged at low speed and the supernatant fluid was transferred to another tube to be used for typing, a test for solubility in bile was done if the quantity permitted. The exudate and heart cultures usually had sufficient growth in from three to six hours to permit typing.

**Nasopharyngeal Cultures**—Often acutely ill adults did not produce sputum that was satisfactory for study, therefore, nasopharyngeal swabs were taken and cultures made on blood agar plates and in dextrose-veal-ascitic broth. The broth cultures usually gave sufficient growth in from six to ten hours to permit typing, in order to check the results, pure cultures of pneumococci were isolated from the plates on the following day.

**Other Specimens**—Cultures of cerebrospinal fluid, thoracentesis fluid, and purulent material from otitis media, mastoiditis and abscesses were grown on blood agar plates and in ascitic broth. Fluids were centrifuged at low speed and occasionally typing could be done on the supernatant fluid.

#### TYPING

**Macroscopic Slide Method**—One loopful of the diagnostic typing serum was placed on a slide, one loopful of the material to be typed was added and mixed. (A

blood culture The other strain that failed to type was isolated from the blood and the cerebrospinal fluid of a patient with primary meningitis, this strain was sent to Miss Cooper, who corroborated our results

#### RESULTS OF TYPE CLASSIFICATION

**Incidence**—The incidence of the various types found in pneumonia and other infections is shown in table 1 In this survey, 91 per cent of the pneumococci were isolated from patients with pneumonia, of these fifty-three (16 per cent) were females The early methods and serums used for classification may have included a few type V pneumococci with type II and some type VIII with type III The incidence of the types found here can be compared with recent Eastern data only in the first three types because the total number of our cases in the other types is too small to be of comparative significance All the figures are from large groups, irrespective of the type of therapy

**Bacteremia**—Bacteremic rates for the various types in the group not serum treated are shown in table 3 A comparative figure is one by Heffron and Anderson,<sup>4</sup>

<sup>3</sup> Heffron, Roderick, and Varley, F. M. Lobar Pneumonia in Massachusetts. *Am J Pub Health* 22: 1230 (Dec.) 1932

the same number also had a bacteremia, of whom sixty-six (66 per cent) died. Bullowa and Wilcox report a mortality of 64 per cent in their bacteremic cases.

mation to Dr Edwin L. Bruck, in whose service the serum was used.

The series of twenty-six cases treated with specific serum is very small, too small for accurate conclusion. There were nineteen cases of type I pneumonia, in ten of which a bacteremia was present. Seven of the bacteremic and two of the nonbacteremic patients died. On the average, admission was on the fifth day of illness, serum was administered on the sixth to seventh day of illness. There were seven cases of type II pneumonia, bacteremia was found in four patients. Two of the bacteremic patients died. On the average, admission was on the third to fourth day of illness, serum was administered on the fifth day of illness.

The mortality rate was not reduced by the use of serum when a bacteremia was present. We believe that the most important factor in determining the prognosis in this small series was the presence or absence of a bacteremia rather than the use or nonuse of serum.

**Purulent Complications.**—Purulent complications in the series of cases of pneumonia not serum treated are

\* Failed to type in all serum.

Of the fifty-three females, fourteen (26.4 per cent) died, ten (18.8 per cent) had a bacteremia, and nine had complications.

The comparative figures on mortality in pneumonia are given in table 5. In comparing these figures, there are several factors which should be considered in each report, such as type of therapy and hospitalization. Bullowa and Wilcox's cases are those listed as having received no specific serum therapy. Sutliff and Finland's<sup>6</sup> data included cases treated and untreated (by serum). Some of Smillie's<sup>7</sup> patients had received serum therapy and some had not been hospitalized.

The incidence, mortality, bacteremic rates and complications for the cases of pneumonia in the group in which we used serums for types I to XXXII are presented in table 3. The time interval is Jan. 1, 1934, to Dec. 1, 1935.

**Serum Therapy.**—While this in the main is a report on the bacteriologic aspect of pneumonia, information regarding the use of therapeutic serum in this hospital will be summarized. We are indebted for this infor-

mation to Dr Edwin L. Bruck, in whose service the serum was used. In the group of twenty-six serum treated cases there were two empyemas in type I and two in type II. In table 8 we compare the figures for

TABLE 7—Purulent Complications in Pneumonia Patients Not Treated with Serum

\* These were found before all diagnostic serums were available.

complications of the combined group of cases serum treated and cases not serum treated with those reported by Sutliff and Finland, whose data are on cases irrespective of the type of therapy. The complications in the other types are presented in table 7 merely by number, for the series is too small to be of comparative significance.

<sup>6</sup> Sutliff W. D. and Finland Maxwell. The Significance of Newly Classified Types of Pneumococci in Disease. J. A. M. A. 101: 1289 (Oct. 21) 1933.

<sup>7</sup> Smillie W. G. The Epidemiology of Lobar Pneumonia. J. A. M. A. 101: 1281 (Oct. 21) 1933.

**Distribution**—The monthly distribution of the various types is given in table 9. Conclusions cannot be drawn regarding the distribution of the specific types, however, the group shows a higher occurrence in the winter months and a lesser frequency in the summer months. In the first year there was a considerable increase in cases of type I pneumonia during May.

\* Sixty one of these were found before all serum were available

The yearly incidence of each type varies considerably, though type I was persistently high during the first two years of the study. During 1935, however, there were only fourteen cases, which is 26.4 per cent of the total cases during that year. Of the thirty-nine cases of type II, thirty were found during the first seven months of the study.

In April 1935 Lister and Ordman<sup>8</sup> of the South African Institute for Medical Research published a lengthy report concerning the epidemiology of pneumonia and the prevention of it by means of vaccine. We regret that the South African classification of types of pneumococci differs from the American, thereby making a direct comparison of statistics not feasible at this time. However, we wish to call attention to this valuable contribution to the study of the epidemiology and prophylaxis of pneumonia.

**Other Etiologic Agents**—The incidence of organisms other than the pneumococcus as the etiologic cause of pneumonia is merely mentioned here. There were fifteen cases of which six were caused by Friedlander's bacillus, four by beta hemolytic streptococci, three by *Staphylococcus aureus*, one by an organism of the *Neisseria* group, and one by *B. coli*.

#### INFECTIONS OTHER THAN PNEUMONIA

Pneumococci were isolated from the blood or purulent material or both from thirty-one patients with no clinical or pathologic evidence of pneumonia. Table 10 shows the incidence, the sources and the mortality of the different types with classification according to clinical

disease. Two of the patients with peritonitis were adult males, one of these (type I) had sputum containing large numbers of type I pneumococci, however, the clinical diagnosis of pneumonia could not be made. In this group of other infections, type III was the most frequently encountered type, similar observations have been reported by several other investigators. Two cases of bilateral mastoiditis showed a type I and II, respectively, in one mastoid and beta hemolytic streptococci in the other mastoid; these cases have not been included in any of the tables.

#### SUMMARY

In an interval of three years, from December 1932 to December 1935, pneumococci were found in 353 patients, of whom 322 adults (91 per cent) had pneumonia.

During the last twenty-three months of this study, diagnostic serums of all available types, that is, I to XXXII, were used. Eighteen types other than the original three were found in either pneumonia or other infections. Only two strains were found that failed to be classified in types I to XXXII.

In pneumonia, type I was the most frequently encountered type, having been found in 138 (42.8 per cent). The order of prevalence of the other types was

TABLE 10—Infections Other Than Pneumonia

Appendiceal abscess	XV	1	1
Peritonitis	I	1	1
	III	1	1
	XXI	1	0
Nephritis	IX	1	1
Pilon abscess	XXII (also B tuberculosis)	1	0
		31	19

\* One of these failed to type when all serums were used

type II, 12.1 per cent; type III, 8.5 per cent; type VII, 4.3 per cent; type VIII, 2.4 per cent.

The incidence, bacteremic rates and mortality of type I (42.8, 49.2 and 44.1 per cent respectively) has been found to be higher than elsewhere.

Seventeen types other than the original three were found in fifty cases of pneumonia. From this small series conclusions cannot be drawn as to the individual clinical characteristics of these types in this locality.

The Neufeld method for typing has been found to be satisfactory.

## Clinical Notes, Suggestions and New Instruments

### CONTACT ULCER OF THE LARYNX

GEORGE H. WOODRUFF, M.D., JOLIET, ILL.

'Contact ulcer of the larynx is a superficial ulceration occurring on one or both sides of the larynx posteriorly, the ulcerated surface coming in contact on phonation with the same region on the opposite cord, the latter being ulcerated or not according to whether the ulceration is unilateral or bilateral.' This definition was given by Chevalier Jackson<sup>1</sup> in 1928 when he made the first presentation of the subject in the literature. Since then he has written several articles in conjunction with Chevalier L. Jackson,<sup>2</sup> who has also written independently on the subject.<sup>3</sup> Together they have seen 264 cases.

Contact ulcer has been reported by very few other men,<sup>4</sup> perhaps not more than three or four, and still remains an uncommon condition as far as the records go. It is probable however that, in the past, many cases have been overlooked or are unreported. In 1935 the Jacksons<sup>2,3</sup> published an extensive article which probably contains all that is known about the condition at the present time.

Peroni<sup>4</sup> of Milan found the typical lesions of contact ulcer in the larynges of two cadavers. This information is included in the latest article by the Jacksons.

#### REPORT OF CASE

**History**—A man, aged 42, seen at the clinic of the Illinois Eye and Ear Infirmary, Aug. 28, 1933, complained of sore throat and a pain in the left ear traveling down the throat. The symptoms first appeared following a severe cold about five months before. At times he had nocturnal choking spells and a sense of constriction in the throat. He had varying degrees of hoarseness, and at times after prolonged use his voice would fail entirely. He had been a salesman and used his voice a great deal, but he was unemployed when he came to the clinic. It was noted that he definitely had a raspy or throaty method of voice production.

**Examination**—On examination the mouth, pharynx, nasal chambers and ears were essentially normal.

Mirror laryngoscopy revealed a small, slightly elevated dull reddish area in the posterior part of the larynx on the left side in the region of the vocal process of the arytenoid cartilage, which is the area of insertion of the posterior end of the vocal cord. Exactly opposite on the right side was a much smaller irregular elevation of similar appearance.

The larynx was otherwise normal except for a moderate injected appearance due to chronic irritation.

No acid-fast bacilli were found in the sputum and the blood Wassermann reaction was negative.

**Treatment**—The patient was advised to go on a regimen of silence, which was imperfectly carried out. Beyond the use of steam inhalations no medication was prescribed.

Little improvement being manifest in four weeks, direct laryngoscopy was done and the elevated mass removed from the left arytenoid with cupped forceps. There was no sensation of resistance when the tissue was being grasped or removed. Following this the voice was much improved though it continued to have a somewhat rasping quality and the other symptoms were also much improved.

Grossly the tissue was a soft reddish mass about 2 mm. in diameter.

The microscopic report was 'chronic granulation tissue beneath epithelium which is thickened.'

From the service of Dr. J. A. Cavanaugh at the Illinois Eye and Ear Infirmary, Chicago.

Several weeks later the symptoms returned and examination showed substantially the original lesion.

Feb. 8, 1934, the small tumor mass was again removed. The pathologic report was the same as that following the first biopsy.

The patient again improved and in one month the larynx had assumed a nearly normal appearance. There appeared to be only a slight thickening of the mucosa at the site of the original lesion. By request the patient appeared at the clinic in February 1936. He was seen by Dr. Cavanaugh, who reports him quite free from his former symptoms, and on mirror laryngoscopy no sign of the former lesions could be seen.

#### COMMENT

The appearance of the affected areas in the larynx corresponded very definitely with one of the types of contact ulcer described by the Jacksons.

In the etiology the important factor is vocal abuse, as is illustrated by our case. In this connection a raspy, throaty method of voice production is usually noted in these cases. The rarity of contact ulcer in women is of interest, because they seldom have the raspy, throaty method of phonation.

The pathogenesis as conceived by Jackson is that the continual pounding of one arytenoid cartilage against the other constantly traumatizes the mucosa in a way that he metaphorically describes "as being between the hammer and the anvil."

The other points in the etiology, as well as the somewhat varying appearance on mirror laryngoscopy and direct laryngoscopy—the pathology, diagnosis and treatment—have been so thoroughly covered in the latest article by Chevalier and Chevalier L. Jackson that they will not be repeated here. The most consistent thing about contact ulcer is its unvarying location on the vocal process of the arytenoid cartilage.

Suffice it to say that Jackson regards vocal rest and reduction in the use of the voice of paramount importance in healing the lesion and preventing its recurrence.

The surgical treatment that is often necessary is the removal of the granuloma and in some cases the necrotic tip of the vocal process of the arytenoid cartilage, when this necrosis exists.

Contact ulcer is one of the conditions that should be considered in patients having long continued hoarseness.

### PRIMARY PNEUMOCOCCUS TYPE XXII MENINGITIS

SIDNEY HIRSCH, M.D., CEDARHURST, N. Y.  
Senior Clinical Assistant Mount Sinai Surgical Outpatient  
Department, New York

Pneumococcus type XXII meningitis is of sufficient rarity to warrant the report of this case. In addition, the profession's lack of familiarity with this formidable infection makes this case of more than passing interest. There are very few conditions that require as much skill to establish an early diagnosis and that give so uniformly a fatal outlook.

#### REPORT OF CASE

H. B., a white man, aged 53, with a negative previous history, awakened Jan. 10, 1936, with a slight frontal headache. He took some acetylsalicylic acid and was able to go to business. The headache remained constantly during the day. Although it was mild he took 30 grains (2 Gm.) of acetylsalicylic acid during that day for relief. At 3 p.m. he was awakened from sleep with an excruciating frontal headache. A physician was called, who found it necessary to give one-fourth grain (0.016 Gm.) of morphine sulfate for relief. Examination was negative except for a temperature of 101° and it was the physician's impression that the patient was suffering from 'grip.' The following morning the patient was very somnolent, although easily aroused. The pupils were almost pin point and respirations were only twelve per minute. It was felt that his drowsiness was due to the morphine. During the day he brightened up, responded intelligently to questioning and had no real complaints. That night his temperature rose to 103° and catheterization was necessary for urinary retention. In view of a negative prostatic examination the retention was ascribed to the morphine. A careful examination of nose, throat, ears and lungs was negative.

The next morning, forty-eight hours after the onset of his headache, he became comatose and could not be aroused. At this time it was noted that there was very slight stiffness of the neck, with a questionable Kernig sign. The patellar reflexes were present and there was no Babinski sign. There was no Brudzinski sign. The nostrils were free of any discharge, there was no sinus tenderness and the ear canals and drums were clear. There was no rash. Arrangements were made for hospitalization.

That afternoon, about fifty hours after the onset, the patient was admitted to the Mount Sinai Hospital. A lumbar puncture showed purulent fluid under markedly increased pressure. The fluid proved negative for organisms on smear and culture. It consisted of myriads of polymorphonuclears but no organisms. The analysis of the fluid was as follows: sugar 25 mg per hundred cubic centimeters, globulin 2 plus, Wassermann reaction, negative, colloidal gold curve negative, examination for tubercle bacilli, negative. Antimeningococcus serum was given. The patient's condition rapidly became worse. A repeated neurologic examination just prior to the lumbar puncture revealed a marked stiffness of the neck with a definitely positive Kernig sign although absent patellar reflexes. Vesical catheterization revealed grossly hemorrhagic urine. A white cell count showed 36 000, with 94 per cent polymorphonuclears. A blood culture was reported negative. The following morning another lumbar puncture was done. The fluid escaped very slowly. A blockage due to adhesions being feared, a cisternal puncture was performed. Fluid here also escaped very slowly. A smear of this fluid was negative for organisms but a culture was later reported positive for pneumococcus type XXII. The patient's course continued rapidly downhill. His temperature gradually rose to 107.8 and he died seventy-two hours after the onset of his illness. No postmortem examination was obtained.

The question of the source of the pneumococci requires discussion. In view of a negative search of its usual foci, nose, throat, sinuses, ears and lungs, and a negative blood culture one may assume that the organism entered the meninges directly from the nasopharynx or from the sphenoidal sinuses.

#### SUMMARY

Primary pneumococcal meningitis is a rare disease but its occasional occurrence necessitates bearing it in mind in evaluating an acutely severe headache and somnolence.

609 Broadway

#### DIHYDROXY ANTHRANOL IN THE TREATMENT OF RINGWORM OF THE FACE, NECK AND ARMS (TINEA CIRCINATA)

MATTHEW MOLITCH, MD, JAMESBURG, N. J.

Ringworm of the face, neck and arms is commonly present wherever children congregate as in schools or institutions. In the New Jersey State Home for Boys we were constantly treating a dozen or more children with this skin disease. They usually come to the attention of the resident physician when the lesion is about one half inch (13 mm) in diameter and in only two out of several hundred were the lesions as large as 3 inches (76 mm) in diameter. Over a period of four years the skin lesions were treated with various ointments including ammoniated mercury and antiseptics such as gentian violet and tincture of iodine in varying percentages. With persistent daily treatments the lesions would clear up in from one to two weeks. As our newly admitted boys seldom had this skin infection it was evident that the disease was spread by contact or indiscriminate use of towels or clothing. Although every one of our more than 500 inmates has his own clothing and towels it is difficult to prevent interchanging as one can imagine.

It is evident that in order to decrease the incidence of ringworm among children it would be necessary to get some drug which would so affect the lesion as to render it sterile. With this thought in mind we tried dihydroxy anthranol<sup>1</sup> and found

that we accomplished our purpose.<sup>2</sup> At first we tried the 0.1 per cent ointment and found it nonirritating and only feebly effective. We then tried the 0.5 per cent ointment and found it both nonirritating and effective. One application caused within a few hours, a light purplish discoloration of the lesion and of the skin adjacent to its border. The next day the skin crinkled and on the third or fourth day it desquamated. No scars or other complications resulted in the twenty-four boys (aged from 9 to 14) treated. As not one additional new case appeared during the past six months it appears that the one application of the 0.5 per cent ointment was sufficient to sterilize the lesion and thus prevent the infection of other children.

The lesions were rarely larger than three-fourths inch (19 mm) in diameter and the two that were much larger required several applications. It is seldom that a child has only one lesion and it is quite usual to find one on the cheek and one on the neck. The diagnoses were made clinically, and no scrapings were made to discover the presence of tinea. The chemical compound dihydroxy-anthranol differs in its structural formula from chrysarobin only by the lack of the methyl group. It has been in use abroad for almost twenty years and in this country for several years. Beerman and his associates<sup>3</sup> who recently published a survey of the literature, found it particularly useful in psoriasis.

#### CONCLUSIONS

1 Twenty-four boys (aged from 9 to 14) with ringworm of the face, neck or arms were treated with dihydroxy-anthranol with excellent results.

2 One application of the 0.5 per cent ointment was sufficient to sterilize the lesions and to prevent the infection of other children.

3 The 0.5 per cent ointment was found to be nonirritating, and no scars or other complications resulted from its use.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION  
OF THE FOLLOWING REPORTS: HOWARD A. CARTER, Secretary

#### FISCHERTHERM ACCEPTABLE

Manufacturer: The Fischer Corporation, Glendale, Calif.

The Fischerterm is designed for medical and surgical diathermy. It is described as a four-tube short wave unit, having two rectifier and two power tubes. The wavelength is approximately 15 meters. The maximum input is said to be 900 watts. Since there is no acceptable method for measuring the output power of short wave machines this value is not given. The total shipping weight including pads and cover, is about 85 pounds. Both pad and cuff electrodes are furnished as standard equipment.

The circuit is of the push-pull Hartley type. By means of the rectifying tubes, direct current is supplied to the plates of the oscillator tubes. The temperature rise of the transformer, after the machine was operated at full load for two hours, came within the limits of safety prescribed by the Council.

An investigation of the unit was made and data were submitted for consideration in accordance with the Rules of the Council. The tissue heating effect in the human thigh was observed. Cuff electrodes were applied to the thigh, one posterior to the hip, the other anterior to the knee. Thermocouples were introduced into the deep lying tissues and also into the subcutaneous tissues, being placed midway between the electrodes and temperature readings were made immediately before and after the treatments during which the thermocouples were removed. After twenty minutes treatment the machine being operated at the patient's tolerance, the temperature rise and final temperature (average of four tests) were observed to be

<sup>1</sup> From the University of Pennsylvania School of Medicine and the New Jersey State Home for Boys.

<sup>2</sup> The Council on Pharmacy and Chemistry issued a preliminary report on Dihydroxy Anthranol (Anthralin) in THE JOURNAL, Jan. 5, 1935, page 48.

<sup>3</sup> Supplied in ointment form (Anthralin ointment) through the courtesy of Dr. G. W. Raiziss, of the Dermatological Research Laboratories, Philadelphia Division of Abbott Laboratories, North Chicago, Ill.  
<sup>3</sup> Beerman, Herman, Kulchar, C. A., Pillbury, D. M., and Stokes, J. H. Dihydroxyanthranol as a substitute for Chrysarobin. J. A. M. A. 104: 2628 (Jan. 5) 1935.

comparable to those temperatures obtained when using a conventional diathermy machine, which was used as a control.

The conventional diathermy currents were applied to the thigh by pad electrodes placed on the medial and lateral aspects of the thigh with approximately one inch of toweling used for spacing. The cuff electrodes were applied with three fourths inch toweling for spacing under the upper cuff and 1½ inch toweling under the lower.

The machine was used in a clinic acceptable to the Council, and the report of the previous investigation was confirmed. The machine gave satisfactory service when used for medical and

### PRELIMINARY REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING PRELIMINARY REPORT

PAUL NICHOLAS LEECH, Secretary

### REFINED AND CONCENTRATED ANTIPNEUMOCOCCIC SERUM TYPE VII-LEDERLE

The Lederle Laboratories, Inc., presented Refined and Concentrated Antipneumococcic Serum Type VII (Lederle) for consideration by the Council. It is claimed to be useful in the treatment of pneumococcic pneumonias of this type, which is one of the twenty-nine groups of pneumococci previously considered to be group IV organisms. The identification of the individual types and the clinical use of the specific serums have been carried out under the direction of Park by his associates Cooper<sup>1</sup> and Bullova.<sup>2</sup> This identification includes them all as former group IV organisms but the following cross relations occur: II and V, III and VIII, VII and XVIII, and XV and XXV.<sup>3</sup> Some of the types have had other designations: type IV includes pneumococcus 10 of Griffith and group IIB of Robinson, type V includes IIA of Avery, type VI includes IIB of Avery, and type VIII includes a typical type III.

About 90 per cent of all pneumonias are attributed to the pneumococcus, and from 25 to 40 per cent of these have been claimed by various workers to be due to "group IV (types IV to XXXII)." In Bullova's<sup>2</sup> series of 1,000 cases, about 7 per cent were found to be due to type VII organisms. Incidence in other types in this series were:

Type I	253	Type VII	69
Type III	115	Type IV	65
Type VIII	98	Type V	60
Type II	79	Type XIV	45

Other twenty four types each less than thirty

Park, in commenting on Bullova's report<sup>2</sup> noted that

It seems strange that physicians do not use good antipneumococcic therapeutic serums when they are available. So far as I know of the frequent types type III is the only one in which serum may not be of benefit.

The New York City Department of Health, in record with this statement distributes its own types I, II, V, VII and XIV antipneumococcic serums. If the demonstration of these various types, the development of specific antiserums, and their application in those cases in which they are specifically indicated by standard methods of typing<sup>4</sup> lessen the mortality in pneumo-

### Clinical Cases Reported by Bullova and Recorded in Leaflet

	No of Cases	Treated	Not Treated	Per Cent Bact	Per Cent Mort
According to the leaflet	121 (104)	19			70

According to the report	136	31		6	7.0
			105	12	21.0

coccic pneumonia, their usefulness could not be questioned. However, the present evidence for the effectiveness of type VII serums as well as for some serums of these less well known types seems somewhat meager.

Bullova's report<sup>2</sup> on typing includes a series of clinical cases which is more extensive than the series recorded in the package enclosure submitted by the Lederle Laboratories, Inc.

Schematic diagram of circuit

surgical diathermy. Burns may occur when this machine is used, but they may be avoided by ordinary precaution; their likelihood to occur is much less than with conventional diathermy.

In view of the favorable report on the unit based on its performance when cuff electrodes were used the Council on Physical Therapy voted to include the Fischertherm in its list of accepted apparatus.

### EMERSON DIAPHRAGM RESPIRATOR, INFANT MODEL, ACCEPTABLE

Manufacturer: J. H. Emerson, Cambridge, Mass.

This infant respirator is a simple apparatus for producing prolonged artificial respiration. It is similar in operation to the adult model previously accepted by the Council (*THE JOURNAL*, Sept. 17, 1932, p. 995). It is sturdily built and its mechanical operation is satisfactory.

According to the manufacturer, 'when a patient is placed in the machine correctly and when the machine is operated as directed, alternate positive and negative pressures adjustable as to rate and amount are created within the machine causing the patient's chest to move as in natural breathing; if natural breathing is not functioning so that the patient will breathe unless the air passage to the lungs is obstructed.'

The machine is operated by an alternating or a direct current motor but by moving one lever hand operation is possible.

Features of this respirator are an all-leather diaphragm to create the pressure variations within the respirator, placed at the end of the machine where it will not catch liquids accidentally spilled in the respirator; a leather relief valve; a variable speed pulley to give a variable respiration rate adjustable during operation; and a dial pressure gage not materially affected by weather. In addition this infant model is equipped with a sponge rubber collar, a simple hood for use while administering oxygen while the machine is in operation and a tilting mechanism which inclines the body of the respirator and the head rest as a unit.

This respirator was used by the Council's investigator. He reported that the respirator is simple to operate and gives satisfactory service for the uses for which it is intended.

In view of the favorable mechanical and clinical performances of the unit the Council on Physical Therapy voted to include the Emerson Diaphragm Respirator, Infant Model, in its list of accepted apparatus.

It is further stated in the firm's package enclosure

Whereas the number of cases is small Bullowa's results are certainly suggestive of a definite therapeutic effect in the specific serum treatment of type VII pneumonias Cooper also states that the serum treatment of cases caused by type VII has been encouraging

The firm did not submit any bibliography for the preparation The Council agrees with Cooper that the results are encouraging, and to a lesser extent with the firm's statement that the results are suggestive of a definite therapeutic effect It is pointed out however that comparative percentages based on such a small series may be entirely misleading

Although the labels for the accepted types of antipneumococcic serum (Lederle) contain the statement that when they are given "early in adequate dosage the clinical results are striking," there does not seem to be sufficient evidence to warrant the use of a similar statement for the type VII preparation, even though the word 'striking' were to be replaced by 'most favorable'

In view of these factors the Council postponed consideration of this antiserum until these workers, or others, have extended the use of this agent to a larger series of cases, and authorized publication of the foregoing preliminary report

## NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION

PAUL NICHOLAS LEECH Secretary

**METYCAINE** (See New and Nonofficial Remedies 1935, p 56)

The following additional dosage form has been accepted

*Metycaine Ophthalmic Ointment 4 per cent* Metycaine 4 per cent in a base consisting of liquid petrolatum and wool fat with small amounts of paraffin white petrolatum and ceresin

**ANTIPNEUMOCOCCIC SERUM** (See New and Nonofficial Remedies, 1935, p 377)

The National Drug Co, Philadelphia

*Antipneumococcic Serum Felton Type I (Refined and Concentrated)*—Prepared by immunizing horses with intravenous injections of virulent and avirulent pneumococci and subcutaneous injections of the supernatant broth culture mediums in which the bacteria had been grown When test bleedings show the serum has reached a sufficient degree of potency full bleeding is made The serum is concentrated by a method similar to that used for antitoxins Marketed in packages containing 10 000 and 20 000 units of type I pneumococcus antibodies

**ANTIPNEUMOCOCCIC SERUM** (See New and Nonofficial Remedies, 1935, p 377)

The National Drug Co, Philadelphia

*Antipneumococcic Serum Types I and II Refined and Concentrated*—An antipneumococcic serum prepared by immunizing horses with intravenous injections of avirulent and virulent pneumococcus antibodies of types I and II The potency of the product is determined and expressed in terms of the unit of Lloyd D Ielton The serum is concentrated by a method similar to that used for antitoxins It is marketed in packages of one syringe containing 10 000 units each of pneumococcus antibodies of types I and II in packages of one syringe containing 20 000 units each of pneumococcus antibodies of types I and II and in packages of one ampule containing 20 000 units each of pneumococcus antibodies of types I and II

**DIPHThERIA TOXOID, ALUM PRECIPITATED (REFINED)** (See New and Nonofficial Remedies 1935, p 395)

Lee Laboratories, Columbus, Ohio

*Diphtheria Toxoid Alum Precipitated Refined*—Diphtheria toxins are altered free from the bacterial cells treated with 0.4 per cent solution of formaldehyde and incubation is carried out at 38 to 40 C for from four to seven weeks in order to destroy all toxicity The absence of toxicity is determined by an intracutaneous test on guinea pigs and by the injection of 5 cc subcutaneously into guinea pigs The skin tests shall show no reaction in from forty-eight to seventy-two hours and the pigs receiving 5 cc shall show no symptoms of diphtheritic poisoning within a five weeks period After the toxins are shown to be completely detoxified and sterile they are precipitated with a 2 per cent solution of alum and allowed to settle The supernatant liquid is siphoned off and the precipitate washed with sterile physiologic solution of sodium chloride This washing process is repeated three times The final volume is then made up to the original volume of the toxin and merthiolate 1:5000 is added as a preservative The regulations of the National Institute of Health are adhered to in checking the immunizing value of every batch pigs are injected subcutaneously with 1 cc of the alum precipitated diphtheria toxoid At the end of six weeks they are bled and their serum must show at least 2 unit of diphtheria antitoxin per cubic centimeter Marketed in packages of one 1 cc vial and 1 cc vials and one 10 cc vial representing respectively one ten and ten immunizing doses

## Committee on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION

FRANKLIN C BING Secretary

### CELLU BRAND TINY BEETS, WATER PACKED

*Distributor*—Chicago Dietetic Supply House Inc, Chicago

*Packer*—Eugene Fruit Growers Association, Eugene, Ore

*Description*—Canned beets, packed in water

*Manufacture*—Beets harvested at the desired degree of maturity, are topped and trimmed, precooked to loosen the skin, mechanically peeled inspected, again trimmed, graded, again inspected and hand packed in cans The cans are filled with water, heated, sealed and processed

*Analysis* (submitted by distributor) —

	per cent
Moisture	87.2
Total solids	12.8
Ash	1.1
Fat (ether extract)	0.2
Protein (N X 6.25)	1.6
Crude fiber	0.9
Starch (diastase method)	7.1
Carbohydrates other than crude fiber (by difference)	9.0

*Calories*—0.4 per gram 11 per ounce

*Claims of Manufacturer*—Choice quality tiny whole beets packed without added sugar or salt For use in special diets in which sugar or salt is proscribed or in quantitative diets of calculated composition

### HAWAIIAN PINEAPPLE

1 MONOLA BRAND CRUSHED, SLICED

2 NEW LIBERTY BRAND CRUSHED SLICED

3 RED SHIELD BRAND CRUSHED SLICED

*Distributors*—1 and 3 Wm Steinhilber Company, Milwaukee 2 Prospect Supply Company, Yonkers N Y

*Packer*—Hawaiian Pineapple Co Ltd, San Francisco

*Description*—Canned pineapple packed in concentrated pineapple juice with added sucrose The same as Dole Hawaiian canned pineapple products (THE JOURNAL, April 8 1933, p 1106, and April 29 1933, p 1338)

### 1776 GEROLIUM BREAKFAST CEREAL

*Manufacturer*—The Shellbarger Mill & Elevator Company, Salina, Kan

*Description*—Wheat cereal containing the embryo and considerable of the bran

*Manufacture*—Wheat is cleaned and milled by the usual procedure Wheat middlings containing considerable of the bran and the embryo is packed in cartons

*Analysis* (submitted by manufacturer) —

	per cent
Moisture	13.5
Ash	1.2
Fat (ether extraction method)	1.4
Protein (N X 5.7)	10.8
Crude fiber	1.3
Carbohydrates other than crude fiber (by difference)	72.0

*Calories*—3.4 per gram 97 per ounce

### ADVERTISING LEAFLET THE CANNED FOOD HANDBOOK

## THE PARATHYROID GLANDS AND DISEASES OF THE BONES

Evidence from a variety of experimental and clinical sources has established that the skeletal system is more than a mere inert supporting structure. Throughout life it serves an equally important function as a reservoir for calcium and phosphorus in which or from which these elements may be deposited or withdrawn according to the needs of the body. The amount of calcium and of phosphorus stored in the bones is dependent on a balance between two processes, the deposition of the quantity absorbed from the gastrointestinal tract and the withdrawal of these elements under the influence of the hormone secreted by the parathyroid glands. The importance of the first of these factors and the relation of vitamin D to the process has been appreciated for many years. The nature of the second process, however, is not so well understood. The parathyroid hormone appears to control the concentration of calcium in the blood by mobilizing this element from the bones as the need arises. Possibly the hormone exerts a direct stimulatory action on the osteoclasts of the bones but conclusive proof is still lacking. Some further insight into the mechanism of parathyroid hormone action has been supplied recently by a series of experiments<sup>1</sup> which seem to show that this substance plays a decisive part in the regulation of the calcium ion concentration of the blood. The removal of the parathyroid glands in experimental animals produced a consistent lowering of the calcium ion concentration of the blood, whereas the administration of parathyroid extract caused an increase in the value above the normal level. A practical method of determining the calcium ion concentration of the blood and a lucid discussion of the clinical significance of these values as an index to abnormal function of the parathyroid glands have been given by the same investigators.<sup>2</sup>

In view of the definite relation of the parathyroid hormone to the withdrawal of calcium salts from the bones, pathologic processes affecting one may be expected to produce profound changes in the other. Clinical results, reported in two recent articles,<sup>3</sup> sustain this expectation. One of the most striking example is found in the disease osteitis fibrosa (parathyroid osteitis, von Recklinghausen's disease), which is caused by a tumor of one or more of the parathyroid gland. This disease has therefore been classed as a condition of "primary hyperparathyroidism." The hypertrophy of the gland apparently results in an increase in the amount of parathyroid hormone secreted in the blood stream and thus produces demineralization of the bones. Gradually, generalized osteoporosis and skeletal deformities develop. Concrete evidence of the mobilization of calcium salts is obtained by a chemical analysis of the blood and urine. There is a significant increase in the total calcium and calcium ion concentrations of the blood and an accelerated rate of urinary excretion of the element, resulting in a negative calcium balance. A concomitant decrease in inorganic phosphate of the blood and an increase in serum phosphatase activity have also been described. Final conclusive evidence relating osteitis fibrosa to a hyperactivity of the parathyroid glands is the consistent effect of surgical removal of a proper amount of the gland, or the diminution of its activity by sufficient roentgen irradiation. This usually produces a decrease in serum calcium to normal values, an increased retention of calcium, and clinical improvement in the patient.

Not only may pathologic changes in the parathyroids produce changes in the bones, but also alterations in the structure and activity of the parathyroid glands may be encountered in certain bone diseases. This condition may be termed "secondary hyperparathyroidism." Typical examples of this relationship are the bone diseases rickets, "renal rickets" and osteomalacia, in which there is an enlargement of the parathyroid glands, presumably representing a compensatory response. Similar enlargement of the parathyroids and an accompanying hypercalcemia have been described in some cases of carcinoma with metastases to the bone, chronic nephritis, nephrolithiasis and multiple myeloma. In Paget's disease however there apparently is little involvement of the parathyroid glands, since these remain morphologically normal and there is no hypercalcemia. Studies in the clinic and on animals emphasize again but in a new direction the intimate dependence of metabolism on the activity of hormones. The day may not be far away when therapy will shift from symptomatic treatment to the more fundamental device of augmenting or reducing the supply of specific circulating hormones.

## METABOLISM DURING PREGNANCY

One of the phenomena of life that early attracted the attention of scientific investigators is the reproductive cycle. A vast amount of literature is concerned with the metabolism during pregnancy and the metabolic relationships between the fetal organism and its maternal host. Only during the last ten years has renewed interest in this field, supplemented by more modern analytic methods, yielded interesting data of the type necessary for meeting the fundamental problem of the health and the preservation of the mother and the welfare of the infant. The work being conducted in the Research Laboratory of the Children's Fund of Michigan in Detroit and the studies initiated at the University of Chicago and actively continued at the Oklahoma Agricultural and Mechanical College, are worthy examples of well directed efforts to secure data regarding metabolism during pregnancy.

Several modes of approach have been utilized in the past to determine the nutritional and dietary needs of human pregnancy. Studies have been made of the dietaries of healthy women who are showing a normal reproductive cycle. The chemical alterations of the blood of the mother during pregnancy and under various physiologic conditions have been determined and attempts made to interpret the data from the point of view of metabolic significance. Also, it has been possible to obtain interesting information by the quantitative analysis of human fetuses at varying stages of development, thus information regarding the nature of the materials that must be supplied to meet the nutritional needs of pregnancy are obtained. The fourth method, and the one that has been employed in the more recent investigations of metabolism during pregnancy, utilizes the classic technic of balance experiments. Exact chemical analyses of the materials ingested and of the excreta show the quantities of the various substances, either inorganic or organic, that are retained for use during the period under investigation. Comparison of this information with the balances of nonpregnant subjects under optimal conditions yields valuable information regarding the total dietary requirements of maternity, including those of the mother herself. These include the needs arising from the added tasks of reproduction, fetal development and the necessity of the organism to provide for lactation. There are now available suggestive experimental data<sup>1</sup> bearing on balance studies during pregnancy for calcium, phosphorus, sodium potassium magnesium sulfur, chlorine iron and nitrogen. The results indicate a high retention of calcium and to a less extent of phosphorus and of magnesium. The storage of nitrogen tends to be low and is definitely inadequate for iron. The Oklahoma studies revealed an apparently high storage of calcium nitrogen and iron in early pregnancy quite

independent of and far in excess of fetal needs when dietary conditions were favorable for storage. In these instances there was no evidence of increased retention which may be observed in women receiving deficient diets during late pregnancy and corresponding to the period of high fetal demand.

The Detroit group<sup>2</sup> has recently presented a case study of the continuous nitrogen utilization of a multipara which is particularly noteworthy for the length of the period of observation and its completeness. The subject had been under more or less close observation for eight years but the present study covered the last 145 days of gestation, parturition, the puerperium and the first eight weeks of lactation. During the last 145 days of gestation, 377 Gm of nitrogen was stored by the mother, during delivery loss of body fluid and the fetal membranes accounted for 55 Gm of nitrogen, during the lying-in period 45 Gm of nitrogen was lost, and 38 Gm was secreted into the milk in the last forty-three days of observation. There was thus a net gain to the maternal organism of approximately 250 Gm of nitrogen during the period of observation. This study provides a striking example of the material gain to the maternal organism resulting from a completed reproductive cycle.

Dogmatic conclusions cannot be derived from the experimental results that have been obtained thus far from balance studies. There is an evident variation in the metabolism among individuals of an experimental group as well as in the same person at different times. Nevertheless, the results do offer definite indications of some of the significant nutritional needs of pregnancy. When supplemented by further studies they will contribute much to the sum of our knowledge of the metabolism of women during the reproductive cycle.

## CRIMINAL BEHAVIOR IN THE LATER PERIOD OF LIFE

Crime, it has been generally observed is a form of behavior most common to the young. According to Schroeder,<sup>1</sup> only three references to medical studies of the older offenders against the law have been made over the last fifteen years. The material from which Schroeder's studies were made was collected from examinations of prisoners committed to the Illinois State Penitentiary convicted of felonious crimes. Four hundred and eighty-six prisoners were investigated unselected except that one half were under and the other half over 40 years of age. Those over 40 constituted 10.2 per cent of a total of 1,083 serial admissions. All crimes were classified as either robbery, larceny, burglary, murder, fraud or sex. Less than 7 per cent which did not fall in any of these groups, were classified as miscellaneous. The larger proportion of crimes were distributed among the murder, fraud

<sup>1</sup> Summary of this work in which earlier references will be found is given by Coons, C. M. *Studies in Metabolism During Pregnancy*, Bull. 223, Agricultural Experiment Station, Oklahoma Agricultural and Mechanical College.

<sup>2</sup> Hether, Helen A., Hummell, Frances C., Erickson, Betty A. and Macay, Icie C. *J. Nutrition* 10: 5-9 (Dec. 10) 1935. References to earlier paper in this series will be found here.

<sup>1</sup> Schroeder, I. J. *Criminal Behavior in the Later Period of Life*, Am. J. Psychiat. 92: 915 (Jan.) 1936.

and sex groups, in contrast to the distribution in a comparable group including all ages. In the murder group the proportion was two and one-half times larger than that for the same crime for the all age group, whereas in fraud and sex the proportion was four times greater. The native born white made up the larger proportion of the group studied, representing 60 per cent. Eighteen and nine-tenths per cent were of foreign birth, in contrast to a much lower percentage of this group among admissions of all ages. Nineteen per cent were native born Negroes.

The educational achievement was only approximately determined, as it depended on the statement of the prisoner himself. There was a limitation of schooling, only fourteen men had any college training. Thirty-three reported high school training. The largest group (133) fell in the range including the fourth to the eighth grade. Thirty-eight had achieved only the primary grades, and twenty-five showed no schooling whatever. The intelligence level was based on the measurements obtained by the use of the Army Alpha group test, the use of the individual Stanford-Binet test for those falling below the dull group, and the use of the performance tests for the illiterate. When compared with a group of prisoners of all ages, the special group studied was found to have almost four times as many mental defectives as the general group. Furthermore, this large proportion of defectives belonged primarily to sex and murder groups. The fraud group showed a distinctly higher intelligence level. Psychiatric examination indicated that 37.4 per cent fell in the group classified as inadequate personality, 23 per cent in the egocentric group and 11.9 per cent in the unstable group, 13 per cent were found to show signs of psychopathy, of which the largest proportion was psychopathic personality. Seven were found to be psychotic and a like number were classified under alcoholic deterioration. Five were psychoneurotic, three showed senile deterioration and two were epileptic, 9.4 per cent were found to be free from personality fault. Syphilis of the central nervous system was found in two cases, and four were left undiagnosed.

It is difficult in many instances to evaluate the previous criminal record. Except for confinement within a penitentiary or reformatory, serious doubt must be raised as to the validity of a history of previous arrests and convictions. For the group over 40 years of age 51.9 per cent had a record of previous convictions of one form or another, whereas in a similar group of unselected prisoners under 40 years of age 65.1 per cent showed a previous criminal record. Also the further significance of a previous criminal record and types of crime was studied. The relatively small number of prisoners in the older age group convicted of robbery, larceny and burglary showed a high percentage of previous penitentiary sentence. The murder, fraud and sex groups showed only half as great a frequency of previous sentence.

From this study it seems fairly evident, according to Schroeder, that in the main persons who commit crime after 40 years of age represent a distinct group. They tend to commit crimes of violence, such as murder and sex crimes and also fraud. Those who commit the first two crimes tend to be as a group relatively free from early records of delinquency and crime. Of the group convicted of fraud, the criminal behavior tends to be a continuation of a pattern established at an earlier age. The smaller numbers whose crime is primarily for gain tend to show an extensive earlier criminal record. The older group studied included many men coming from foreign countries. Possibly their inability to adapt themselves may be expressed in the violence of their behavior. They are on the whole distinguished by a general lowering of intelligence, although this may be in large part determined by the method by which they are measured. They show a greater limitation of educational achievement, which may perhaps be explained by a relatively greater limitation of their opportunities, than that of the younger criminal of today. The fact that there is such a marked drop in previous criminal record after the 30 year group must be considered particularly significant. The conclusion, however, that crime ends with the beginning of the second period of life cannot be definitely shown by this study. There is definite evidence, Schroeder believes, that factors within the individual, perhaps constitutional in character, do determine not only the distinctive character of the criminal after 40 but also the relative cessation of criminal activities at about the age of 40. Further studies along these lines should eventually do much to clarify the medical factors surrounding the criminal activity of the later years of life.

## Current Comment

### THE PATHOLOGY OF IDENTICAL TWINS

The possibility of determining the relative roles of heredity and environment based on a study of identical twins has not yet been fully explored. De Lange<sup>1</sup> has recently recorded three abnormal states in three pairs of identical twins. The first pair of boys were 5½ months old when studied. They had a maternal aunt with pyloric stenosis who was under the care of the author in 1921. Both children also had pyloric stenosis, for which it was necessary to perform the Rammstedt operation. The subsequent course was good. The second pair of identical twin boys, within the first month of their lives, developed bilateral scrotal hernia. The author was able to find only one other observation of bilateral hernia in identical twins, but the original publication of this case could not be consulted. The final case was that of twin girls, one of whom was admitted to the hospital on account of an acute glandular swelling at the angle of the jaw at the age of about 9 months. Both children had natiform skulls with

<sup>1</sup> De Lange, Cornelia. A Contribution to the Pathology of Identical Twins. *Arch. Dis. Childhood* 11: 39 (Feb) 1936.

some hydrocephalus, although these changes were more severe in one of the pair than in the other. This condition seemed to be in no way related to prematurity, syphilis or rickets. Further studies of pathologic disorders in monozygotic twins will of necessity be slow. Nevertheless, it is to be expected that a vast amount of light will eventually be thrown on the relative roles of hereditary and acquired diseases by this means.

## Association News

### RADIO BROADCASTS

The American Medical Association broadcasts over WEAf, the Red network instead of the Blue as formerly, and certain additional stations of the National Broadcasting Company at 5 p. m. eastern daylight time (3 o'clock central standard time, 2 o'clock mountain time 1 o'clock Pacific time) each Tuesday, presenting a dramatized program with incidental music under the general theme of "Medical Emergencies and How They Are Met." The title of the program is "Your Health." The program is recognizable by a musical salutation through which the voice of the announcer offers the toast "Ladies and gentlemen, your health!" The theme of the program is repeated each week in the opening announcement, which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

**Red Network**—The stations on the Red network of the National Broadcasting Company are WEAf, WEEI, WTIC, WJAR, WTAG, WCHS, KYW, WFBR, WRC, WGY, WBEN, WCAE, WTAM, WWJ, WMAQ, KSD, WHO, WOW, WDAF.

**Pacific Network**—The stations on the Pacific network are KGO, KPO, KFI, KGW, KOMO, KHQ, KFSD, KTAR.

Network programs are broadcast locally or omitted at the discretion of the local station. The lists indicate stations to which programs are available.

The last two programs of the present series are as follows:

May 5: Maternal Care. W. W. Bauer. 15 D.

May 12: Medicine Marching Forward. W. W. Bauer. 15 D.

A new series is under consideration for the autumn and winter of 1936-1937.

### BROADCASTS FROM THE KANSAS CITY SESSION

Special radio programs will be broadcast from Kansas City during the week of the annual session.

#### NATIONAL BROADCASTING COMPANY

The following programs will be delivered over a network of the National Broadcasting Company:

May 11, 3:30 p. m. "Nutrition and the Future of Man" by Dr. James S. McLester, President of the American Medical Association. Fifteen minutes.

May 12, 3 p. m. "Medicine Marching Forward." The regular dramatized program "Your Health" (originating in Chicago) based on papers or exhibits presented at the convention. Dr. W. W. Bauer. Thirty minutes.

May 13, 11 a. m. An interview about the Scientific Exhibit with Dr. Morris Fishbein. Fifteen minutes.

#### COLUMBIA BROADCASTING SYSTEM

The following programs will be broadcast over a network of the Columbia Broadcasting System:

May 11, 1:30 p. m. An interview with one or more distinguished foreign visitors by Dr. Morris Fishbein. Subject to be announced. Fifteen minutes.

May 15, 2 p. m. A news broadcast outlining the main events of the convention. Dr. W. W. Bauer. Fifteen minutes.

May 15, 8:45 p. m. "Medicine Yesterday and Today." An interview with dramatizations (originating in Chicago) based

on papers or exhibits presented at the convention. Dr. Paul A. Teschner and Columbia Broadcasting System commentator. Thirty minutes.

The hour given is central standard time, eastern standard time is one hour later, mountain time one hour earlier, and Pacific time two hours earlier. Daylight saving time in each locality is one hour earlier.

### ANNUAL CONGRESS ON MEDICAL EDUCATION, MEDICAL LICENSURE AND HOSPITALS

Thirty Second Annual Meeting held in Chicago Feb. 17 and 18, 1936

(Continued from page 1501)

DR. IRVIN D. METZGER, Pittsburgh, in the Chair

#### THE FEDERATION OF STATE MEDICAL BOARDS

FEBRUARY 18—AFTERNOON

#### Narcotic Legislation in Relation to Medical Licensure

DR. WILLIAM C. WOODWARD, Chicago. Authority over narcotic drugs is divided between the federal government and the state governments. Under the constitution the federal government has exclusive authority over the importation and exportation of narcotic drugs, interstate commerce in narcotic drugs, narcotic drugs in the mails and narcotic drugs in the several areas which under the constitution, are under exclusively federal control. The federal government has authority, too, to levy taxes on narcotic drugs, as it has done under the Harrison Narcotic Act, but the several states also levy on them. Finally, under its treaty-making power the federal government has authority to make and enforce such laws as it can constitutionally enact and as are necessary to carry into effect any treaty that the federal government can constitutionally make for the international control of narcotic drugs. All other authority over narcotic drugs is vested in the several states.

The only federal law with which we can now concern ourselves is the Harrison Narcotic Act. Physicians generally do not seem to understand that legally the Harrison Narcotic Act is only a tax measure. Under the Harrison Narcotic Act the federal government does not undertake to say who may and who may not manufacture, sell and use narcotic drugs. It goes no further than to lay down certain requirements with which those who manufacture, sell and use such drugs must comply—all such requirements being in theory at least, necessary for the collection of the tax imposed by the act. A person authorized by the law of the state to manufacture, sell or use narcotic drugs is entitled to register under the Harrison Narcotic Act, and the federal government cannot deny, suspend or cancel his registration.

The right to use narcotic drugs professionally is incident to the right to practice medicine, dentistry and pharmacy. The licensing boards that issue, suspend and revoke licenses to practice the professions named are therefore responsible for the fitness of their licensees to use narcotic drugs in the course of their practice. It is the duty of the licensing agency to determine before a license is issued whether an applicant is or is not fit to be licensed. Its duty is not as clear with respect to the collection from day to day of evidence of the fitness or unfitness of persons already licensed that it is its duty to supervise the professional conduct of its licensees. Theoretically, the licensing agency should assume that function. Practically, probably no such agency has been provided with a field force large enough to enable it effectively to do so.

The United States Bureau of Narcotics is in a strategic position for the discovery and reporting of narcotic addiction or at least of addiction to opium and coca leaves and their compounds and derivatives. This bureau has inspectors scattered throughout the United States primarily for the enforcement of the Harrison Narcotic Act and its inspectors necessarily learn the identity of drug addicts and of persons convicted of violation of the act. In 1933 the Bureau of Narcotics reported seventy-two physicians as narcotic addicts to the medical licensing boards of the states. The cases of 248 physicians were pending at the beginning of the year. Two

hundred and fifty-six reported cases of addiction were pending before medical licensing boards at the beginning of 1934. To this number the Bureau of Narcotics added 126 cases during the year. Three hundred and eight cases remained unacted on at the termination of 1934. Action by medical licensing boards was not satisfactory on reports by the Bureau of Narcotics of cases in which physicians had been found guilty of violations of the Harrison Narcotic Act. At the beginning of 1933 212 cases were pending. Eighty-eight were reported during the year. There remained unacted on at the close of the year 241 cases.

Three hundred and thirty-nine cases were pending before medical licensing boards during 1934 in which licentiates had been convicted of violation of the Harrison Narcotic Act. In nineteen, or 5.6 per cent, licenses were revoked, in seven, or 2.1 per cent, licenses were suspended, in nineteen, or 5.6 per cent, licentiates were put on probation, in four, or 1.2 per cent, licentiates were admonished, and fifteen cases, or 4.4 per cent, were dismissed without disciplinary action. There remained at the close of the year 275 cases, or 81.1 per cent, not acted on.

These figures must not be construed as evidence of incompetence of medical licensing boards or of unwillingness on the part of boards to do their duty. However, it should certainly have been possible to dispose of a larger number of cases. Hardly any of the medical licensing boards of the country, probably none of them, are provided with inspection forces sufficient to enable them to supervise the activities of the physicians whom they license. For the evidence necessary to enable them to do so they must rely on outside agencies for information and the duty, if any, of such agencies to furnish information is in general poorly defined. In twenty-four states the duty of enforcing the narcotic law is placed on the state health agency, in nine states on the state board of pharmacy, in three states on the licensing board or department, and in one state each on the commissioner of agriculture, the board of public welfare, the narcotic drug board, and the department of justice and safety. In ten states the duty of enforcing the act is not specifically assigned to any state agency. The uniform narcotic drug act, which has recently been enacted in substantially its original form in twenty-three states and in modified forms in five others, seeks to mitigate the bad effect of the inadequacy of inspection forces by providing specifically that all peace officers within the state and all county attorneys shall cooperate to enforce its provisions. To improve the situation further the uniform state narcotic drug act provides that, on the conviction of any licensed person of any violation of it, a copy of the judgment and sentence and of the opinion of the court shall be sent to the board or officer by whom the convicted defendant has been licensed to practice his profession or to carry on his business, and that the court may in its discretion suspend or revoke the license of the convicted defendant.

Strange as it may seem, physicians and pharmacists in some jurisdictions have objected to vesting in the courts authority to suspend or revoke licenses. The evidence in the case is before the court, and action can be economically, promptly and effectively taken. The licensing board is constituted in effect an appellate court, something superior to a trial court. What justification there can be for the delay and annoyance, trouble and expense of an additional hearing before disciplinary action is taken, it is difficult to conceive. Probably failure of prompt action in some cases lies in the fact that action must be taken by one board made up of men who are serving only on a part time basis, who are expected to function for an entire state. When they sit as a court they may have to sit in parts of the state remote from their homes and their places of practice, otherwise it is necessary to bring witnesses long distances to the central point at which the board is sitting. The taking of evidence by depositions in a few cases may help the situation but it cannot cure it.

#### Enforcement Procedure

Dr. THOMAS J. CROWE, Dallas, Texas. The Texas annual registration law provides that on January 1 each year all licensed physicians shall pay a registration fee of \$2, which if not paid within sixty days automatically suspends the delinquent practitioner's license until all fees in arrears and a penalty of

\$1 are paid, when the license is automatically reinstated with any other requirement. Besides giving the board the pre-address and professional record of every licensed practitioner the state, annual registration produces a fund of about \$100 a year with which to enforce the law. As a protection against unscrupulous characters, we require all application forms to be completely executed and certified before a notary public. Applications from foreigners shall bear the signature and seal of the authoritative officer of the college of graduation and his signature and seal shall be authenticated by the United States consul of the district in which the college is located. The Texas board commenced investigations in 1932 with one operative in the field. It now has four. That we may get the greatest number of prosecutions with the least expenditure of money and time we have instructed the members of our county medical societies when reporting violations, to give the full name and correct address of the violator and the names and addresses of several persons treated by him within the two years who paid all or part of his fee for service. All such information in hand the investigator without disclosing the name of his informant, may go direct to the persons treated in a day or two get information on which to file complaint for prosecution. If one who has been convicted of violation of the practice act resumes illegal activities, an injunction procedure may be commenced against him which if granted restrains him from future practice or subject him to the penalty for contempt of court, which is severe. Since the most troublesome type of violator was trained mostly in advertising and how to evade conviction, "great care must be given to the selection of jurors" for the trial of a practice act violation in order to prevent the defendant's counsel getting as many as possible of the violator's patrons or friends on the jury to vote for acquittal or hold for mistrial. Our investigators are required to report by postal card at the end of each day, stating where they have persons interviewed on the date of card, and where they may be reached, if needed, on the following day. Membership in cooperation with better business bureaus has enabled us to contact municipal authorities, civic, social, school, fraternal, police and religious organizations and even the newspapers and principal hotels in helping us to keep out of Texas medical false free lecturers and other impostors. We circulate the names of chambers of commerce of Texas, our district or county attorneys, sheriffs and county medical societies of the appearance in the state of undesirable characters. The newspapers are informed as to the practices of such impostors. When possible we send photographs, descriptions, finger prints and other means of identification. Mr. J. J. Biggins, supervisor of personnel for the twelfth district of Texas, sends his inspectors to hearings of complaints against physicians, and he will not issue a narcotic permit to an applicant whose name does not appear in our directory until assured by the board that he is licensed and has paid the annual registration fee. This cooperation made our registration 100 per cent effective, for which we are duly thankful. Our board's address is on the mailing list of the Federal Trade Commission, in order to get its monthly reports, from which we transfer to suitable cards, for filing the commission's 'cease and desist,' 'misbranding' and 'false orders' to manufacturers, distributors and peddlers of misrepresented medicinal preparations and appliances. We find the government's orders very convincing and effective in stopping the advertising and marketing of such worthless products. Every state board should have a file of this kind. We maintain a "crooks and convictions" file, containing information on the holders of fraudulent medical credentials. All secretaries should maintain such a time and trouble saver. It will compensate many times for the trouble of keeping it up to date. We have five complete records of all registered practitioners in Texas—the annual directory, by serial number of license certificates by serial number of annual permits, a permanent 100 subdivided book, and last most convenient and decidedly most used, a card system in ten drawers of a large, fireproof safe containing 7,000 cards indexed in 480 subdivisions, front of each of which bears the full name and address of registrant and the back his complete, historical record. It can make a complete report of any physician in the state,

telephone or otherwise, in less than one minute. In the same safe we have a file of deceased physicians and another of those who are retired.

DR HERBERT M. PLATTER, Columbus, Ohio. In Ohio our enforcement division consists of two investigators at present who have served the department for more than fifteen years. They are thoroughly familiar with the decisions of the courts and know what evidence is necessary to obtain before the submission of a case to the prosecuting attorney of the county in which the offense has been committed. During the course of a year these inspectors investigate about 600 cases. The expense for this service approximates \$8,000. Ohio does not have an annual registration law. We enjoy the cooperation of other state departments, the state medical association, local medical societies, better business bureaus and the federal narcotic department. The usual offenses against medical practice acts in the several states are classified as misdemeanors. Too frequently the trials are postponed repeatedly because they are included in heavy criminal dockets and never reached, even though strenuous attempts are made to have them brought to trial. Our greatest deterrent in Ohio has been delay. This has been particularly evident during the past six years. The number of convictions obtained has fallen off, too many fines have been suspended by the courts and too many cases remain pending in spite of our attempts to bring them to trial. Many provisions in our medical practice acts should be repealed and an honest effort put forth to develop a single standard of qualification for all who would practice the healing art. Great Britain points the way in this particular by giving legal recognition to one type of practitioner. In spite of our strenuous efforts to enforce our laws, the results have not been satisfactory, largely, I believe, because the idea of toleration is firmly fixed in the American social order.

#### Aggressive versus Passive Attitudes of State Board Members

DR ARTHUR C. MORCAN, Philadelphia. The objections against enforcement of medical laws in this country have come from the unlearned or poorly trained cultists or from those who, not having been successful in gaining admission to standard medical colleges, gravitate to the pseudoscientific groups. By far the greater number of students who have gone or are now abroad to secure medical degrees should be looked on with careful scrutiny, if not suspicion. The individual member of a state board must adjust himself to the local situation so far as his personal activity is concerned. He must remember that majority vote in committee or board is the rule. There should be no back door entrance to any state licensure. Applicants coming from foreign schools manifest an eagerness to secure licensure without formally complying with the laws of a state, sometimes making an effort to exert political pressure to accomplish their ends. These procedures are illegal. Politics should not have any influence in the make up of the personnel of state medical boards. In the larger sense politics as a constructive, ethical procedure should have full sway. The personnel of a board of medical examiners should be of such stable character that, if proposed changes in the medical practice act are under contemplation, their advice will be eagerly sought for by legislative committees.

#### Foreign Medical Credentials

DR CHARLES B. PINKHAM, San Francisco. Experience has taught the majority of executive officers of medical examining boards in the United States that credentials from foreign medical institutions cannot always be taken at their face value. Wise is he who without exception meticulously verifies foreign medical documents. Under no circumstances should physicians from abroad be licensed until their credentials have been verified and the identity of the holder established. Extinct in America has become the former practice of flitting from one medical college to another, leaving behind a record of failures in a number of subjects, which had the student remained in attendance would have compelled his repeating the entire course of study for that year. In foreign countries it is not uncommon to find that a medical student has attended as many as six different universities during his course of study. Because German universities keep no check on daily attendance of their

students, it is practically impossible to determine whether a student who has attended several universities during his medical course has completed the required course in one university before he enters another. The political turmoil in both Germany and Russia makes satisfactory verification of medical credentials from either of these countries practically impossible. Even the American consul on whom we often call for assistance frequently is unable to obtain satisfactory verification of foreign credentials. Conditions in Germany may be no different from those existing in other countries including the United States, so far as fraudulent diplomas are concerned yet the difficulty involved in verifying credentials from German and Russian universities should cause the executive officers of all medical examining boards to exercise extreme caution in verifying credentials. This is no easy matter. First must be determined whether such an institution exists as that named on the credentials under investigation.

That it is not difficult to obtain a medical diploma from reputable foreign medical schools was demonstrated by Ray Beeman Horton, erstwhile Missouri veterinarian, who possessed assertedly irregularly issued diplomas of the Kansas City College of Medicine and Surgery and the St. Louis College of Physicians and Surgeons. Both institutions were of such ill repute because of their wholesale issue of questionable diplomas during 1921 to 1925 that the state of Missouri in 1927 revoked the charter of both these schools. Horton, assertedly accused of procuring unworthy persons the right to examination by the State Board of Health of Missouri, was said to have obtained money in excess of \$1,500 for Missouri physician and surgeon's licenses from those who held diplomas of the aforesaid schools. Another instance demonstrating that foreign medical diplomas may be obtained after attending a course of less than one year came to the attention of the California Board of Medical Examiners some years ago. A graduate of a Los Angeles Osteopathic School reported he had entered the University of Berne, Switzerland, in October 1923 and obtained the degree "Doctor of Medicine" from that institution July 16, 1924.

An amendment of section 10 of the California medical practice act requires that every graduate of a foreign medical school who applies after Sept. 15, 1935, for written examination for a physician and surgeon's certificate must file in addition to the medical education requirements already established the following documentary evidence satisfactory to the board of medical examiners: (1) a diploma from an approved medical school, (2) a license to practice medicine in the foreign country wherein is located said medical school, (3) that he has completed a one year internship in an approved hospital in the United States, or (4) that he has completed the senior or fourth or final year in an approved medical school in the United States. Every graduate of a foreign medical school who seeks to qualify for a California reciprocity certificate on a license issued by a sister state after Sept. 15, 1935, must fulfil the requirement just stated. By this amendment the California Board of Medical Examiners believes will be solved many of the uncertainties regarding the sufficiency of the applicant's medical training. As well will this additional educational training serve as a protection to public welfare by augmenting the standard of professional services rendered.

#### The Basic Science Law in Nebraska, After Eight Years

DR HENRY J. LEHNHOFF, Lincoln, Neb. This article was published in the *American Medical Association Bulletin* 31:54 (March) 1936.

#### The Importance of Introducing Psychiatry in Medical Licensure

DR FRANKLIN G. EBAUGH, Denver. I feel that it is no imposition on the candidate for licensure to require of him some knowledge of the physiology which relates somatic function to mentation. Cannon observed the following effects of one emotion—fear—in a cat frightened by a barking dog: (1) increased pulse rate and blood pressure, (2) increased sugar in the blood, (3) increased epinephrine in the blood, (4) decreased coagulation time, (5) increased muscular tone, (6) increased motor activity and restlessness, (7) deep and rapid respiration, (8) dry mouth, pilomotor and vasomotor activity, (9) dilatation of the pupils, (10) defecation and urination, (11) immobility of the stomach. Emotions of such wide influence should be

studied for the conditions under which they occur, the factors which determine them, the manner of control, and methods of prevention. It is not only a question of knowing anatomy, neurology, pathology, biochemistry, physiology, endocrinology or other basic sciences that we want to impress on the student but rather that a correlated understanding of them is essential to the practice of general medicine. These isolated facts must be brought into relation with the complaints of the patient so that therapy will be intelligently directed. There is no other course or discipline in the curriculum which can teach this correlation to more advantage than psychiatry, which deals daily with the functional expression of psychobiologically determined disorders.

Psychiatry itself will benefit by including psychiatric questions in the state board examination. Those schools which are now neglecting thorough psychiatric training will make greater efforts to improve their curriculum. In this way the general level of psychiatric teaching will gradually improve. In time there will develop to the advantage of all concerned a more intelligent agreement as to what constitutes standard psychiatric practice, at the same time avoiding a crystallized uniformity. The student, conscious of his obligation, will make a more determined effort to master the material. Those students who already see the importance of this field will be encouraged to acquire a more extensive acquaintanceship to the mutual benefits of themselves and their patients. Well chosen questions will make information pertinent to this field more readily available, that is, examinations may have a teaching function by stimulating interest in the subject. Public examination will help destroy the mysticism and vague thinking that surround much lay and medical discussion of psychiatry.

The present status of psychiatry with regard to licensure may be easily summarized by stating that Massachusetts is the only state requiring the subject by statute. For several years, questions in psychiatry have been included in the Colorado state board examination in symptomatology. The National Board of Medical Examiners does not require an examination in psychiatry, but this deficiency has been discussed and will probably be remedied. The United States Public Health Service may include psychiatric questions in the examination for general medicine. In West Virginia, questions on psychiatry may be included in the examination on "special medicine" but so far I have seen no evidence that this is done. In several central European countries the licensure proceedings include a separate examination in psychiatry.

Many state board secretaries have stressed the fact that legislative enactment is essential to changing the licensure examination. No doubt this will be possible when the scope of psychiatry is better understood. There has also been an erroneous impression present in the minds of some of the secretaries that lack of adequate teaching caused the omission of psychiatry from licensure procedure. Psychiatric teaching is now developing on a firm footing in the majority of medical schools.

Since it is the privilege of the medical profession to encourage the highest possible standards in the medical school and in licensure, and since a large percentage of medical problems are psychiatric and can be effectively treated by psychiatric methods, it is recommended that the medical graduate of the future should be required by licensure to acquire this training in order that he may render the most proficient service possible. The insertion of incidental questions of psychiatric import in the general medical examination will help meet this need.

#### DISCUSSION

DR IRVIN D. METZGER, Pittsburgh. Mr. Anslinger stated that one of the greatest leaks in narcotics was through the profession of medicine. The members of the department in Washington felt very keenly the fact that they could not be more effective in dealing with physicians because of the apparent indifference of state boards. He told me that less than half a dozen boards are now cooperating with the department with respect to the handling of doctors who are misusing the drugs. The control of physicians in their practice is quite as important as the licensing of physicians, whether in respect to narcotics or otherwise. In Pennsylvania we have a fortunate situation in that we have a bureau of drug control that acts as the advance

agent in bringing cases before us, and we accept court decision, court records, as evidence of conviction, thereby we need not conduct cases.

DR WALTER L. BIERRING, Des Moines, Iowa. The committee consisting of Dr. James N. Baker, J. H. J. Upham and myself to advise the Council on Medical Education and Hospitals as to the attitude of the Federation of State Medical Boards with reference to the procedure to be followed in announcing the results of the survey, report that we presented our statement to the Council in the way of an opportunity to coordinate these three agencies, that the addition of a semiofficial body like the Federation of State Medical Boards would give it some official status, and that a report backed by these three agencies, the educational bodies, the licensing federation and the medical profession, represented by the Council, would do much toward unifying the purpose. We were assured that that was what the Council had in mind all the time. We were assured that the Council expected the Federation of State Medical Boards to take part in these inspections, in those that were still to be made and those that had been done and were to be considered, the Council expected to complete this survey by June, it was expecting, further, to have a meeting in the fall, and it was pleased at the thought that a committee from this body would meet with it at that time. The committee therefore moves that the incoming president appoint a committee of three, of which the president shall be a member, to confer with the Council on Medical Education and Hospitals, with the Association of American Medical Colleges, at the several conferences that are to be held in the final determination of this present movement.

DR J. EARL MCINTYRE, Lansing, Mich. With reference to Dr. Woodward's paper, I think we probably all agree that the narcotic legislation is sufficient, it is a matter of interpretation, and the remedies that Dr. Woodward suggests are not so easily accomplished. Michigan has its problems. We find that the attitude of the department to the bureau has changed in the past few years, but formerly it was very arrogant, and the manner in which they treated the profession created antagonism. Our law does provide that we may accept the findings, a certified copy of conviction by the court. But if this is not done, we have no monies for investigating services. We find it difficult to procure affidavits against doctors on whom there are complaints. I made a trip of 300 miles in the upper portion of the lower peninsula to investigate a government complaint. I found in this little town that the doctor was universally loved, and, if he used narcotics, no one would admit it. We could not do anything about that case. It is difficult in Michigan to accomplish anything on those complaints, because the courts do not accept affidavits. The witnesses who complain must appear in court. Consequently we have the number of cases that have been reported with no action of the board because we cannot secure legal evidence on which to act. We have the same difficulties in procuring evidence for prosecution in Michigan as they have in Texas. We find the same difficulty in the prosecution of cases because the Michigan law specifies that it is the duty of the prosecuting attorney to prosecute all violations of the act in the county in which they occur. The prosecuting attorneys are loath to start any prosecutions unless they are absolutely forced into it. The matter of persecution instead of prosecution was very well brought out, because the sympathetic public is tolerant and broad minded with reference to the medical practice laws. I was interested in the problems that Dr. Platter has in Ohio. The difficulty we have in Michigan is due to the fact that the law specifies that the secretary and executive officer shall file with the state treasurer each month and deposit the proceeds of the board. After that, it is turned over to the auditor general, and we have great difficulty in getting our vouchers on it because it goes into the general fund and is used to defray the expenses of other departments which are not self supporting. Our law also classifies the offenses mostly as misdemeanors. We have the same trouble. If we do get a conviction the defendant is often let off with a light fine or suspended sentence. With reference to Dr. Morgan's paper, I think the standard of requirement must be maintained at any cost and should not yield to any pressure from without. I do not believe excep-

tions should be made because we jeopardize our standing. I think that any other board is justified in looking askance on accepting the reciprocal endorsement of any state that follows those practices. Concerning Dr Ebaugh's paper on psychiatry, Michigan has no provisions for the examination of specialists. Our examinations in the subjects are statutory, specified in the medical practice law of Michigan. Further, we are not allowed to examine specialists, and the scope of the examination must be one of general medicine and to fit the general practitioner. We have no psychiatrist on the Michigan board. We do include some questions under general medicine, under mental and nervous diseases. However I think it is a matter to be taken up with the medical schools possibly by the Council on Medical Education and Hospitals rather than the Federation of State Boards or any state board of licensure.

DR HAROLD RYPINS, Albany, N. Y. About Dr Ebaugh's paper, I have had the opportunity to serve as examiner for the New York Civil Service for applicants for internships and residencies in the state psychiatric hospitals. I found that the percentage of applicants, all of whom were graduates of recognized medical schools, who could even meet my very humble knowledge in the field of psychiatry and neurology was so low as to be surprising. Certainly not more than 40 per cent of them were even able to make a little diagram of a cross section of the cord. If one asked them the difference between symptomatic epilepsy and essential epilepsy that was practically impossible, or the difference between pyramidal tract syndrome and extrapyramidal tract syndrome. In about five years I think it might be very wise for the state boards rather insidiously to include neuropsychiatric questions. I do not believe it is necessary to go to the legislature and ask authority to set up a special examination.

DR ROCK SLESTER, Wauwatosa, Wis. I want to compliment Dr Ebaugh for coming to the defense of this stepchild of medicine. I want to emphasize that psychiatry is not necessarily a specialty. When it is considered that over half of the hospital beds of this country are occupied by psychiatric patients and that it has been repeatedly estimated that over half of the patients who come to the general practitioner's office fall into that broad group of psychoneuroses and it is this large group of patients who are drifting to the chiropractor, the osteopath and the naturopath and the various lack of understanding, it is a problem of everyday life. It is high time that this work that Dr Ebaugh is recognized by our medical colleges and by the state boards.

DR MCINTYRE, Dr Alvin G. Koehler of Oshkosh, Wis., has asked what pronouncement the Federation of State Medical Boards has made respecting graduates from foreign schools. I will tell what Michigan has done. In 1930 Michigan required first citizenship papers. Also since 1930 Michigan has required that all foreign applicants irrespective of their schools must be certified to by the American consul in the foreign city where the medical school is located or by the American embassy. In addition, we require that they spend an extra year in a class A medical school of the United States and one extra year in an approved United States hospital serving a twelve months rotating internship. This so far has been very beneficial to Michigan in our endeavor to enforce the board's rulings.

DR METZGER. I will read a statement of what is required in Pennsylvania. I will insert what our requirements are and we must be exacting in the East because we have them coming in droves now. Some years ago it was reported that there were about 2,000 American students studying abroad. Aside from those that are of foreign birth we have a lot of them coming. There will be more of them. There should be some uniformity if we can attain it in the various states. In the matter of preliminary education they must have credentials that satisfy the department of public instruction. If they have had foreign preliminary education *visa* credentials must be presented from the foreign country. In medical education we require an outline of the subjects studied throughout the course, in the original language of the school with a

certified translation into English. This is done because of the fact that there are some getting diplomas from foreign schools that do not follow out the full course. Second certification on the Pennsylvania blank of the fact that he graduated from the school giving the dates. Third, a recent, unmounted photograph with a state label attached on which the dean has certified to the identification of both the student's likeness and his handwriting. Next, a certification of the fact that the course of medicine studied by the applicant entitles him scholastically to licensure for the practice of medicine in the country in which the school is located. That means that they cannot take the short-cut courses. Each of these credentials and certifications must be signed by the authorized persons and, if received in a foreign country, must be *visa*ed by the American consul. That is essential to make it a legal document. American citizenship or a declaration of intention to become an American citizen is required of all candidates. An internship in America, and preferably in one of our approved hospitals in Pennsylvania is required of all foreign graduates. The credentials must be approved by the state board of medical education and licensure, or by a member thereof before the candidate may be admitted to internship in a hospital approved by this board. The examination must be both written and a bedside examination for all foreign graduates.

DR W. SCOTT NAY, Underhill, N. Y. I have had several letters from graduates of foreign schools, and I wrote them that we did not care to admit them under any circumstances for the reason that we have accepted some of them, granting them our certificates. That is the last we have ever heard of them. We think we have physicians enough here without admitting foreigners. I would mention those who come from the Italian schools and have wished to locate in places such as Barre and Pittsford, Vt., where there is so much granite cut. A number succeeded in getting in. They have stayed for a short time and then have gone away. The only thing we do is to tell them that we do not care to accept their applications.

DR GEORGE M. WILLIAMSON, Grand Forks, N. D. In North Dakota we have practically the same regulations that Dr McIntyre said the state of Michigan has. Candidates have to go through the certification with regard to identification and then spend a year in a class A medical school and a year internship.

DR HAROLD L. MORRIS, Detroit. What are the subjects in which examinations are held by the basic science board of Nebraska? If the medical student passes those six subjects does the state board of registration require him to take a second examination?

DR HENRY J. LEHNHOFF, Lincoln, Neb. The examination in the basic sciences will be waived in case the applicant can send satisfactory credentials to the basic science board that he has passed a favorable examination in those five basic science subjects. It would not be expected that a chiropractor could give credentials that would permit him to have a waiver. Dr Baker asked whether some chiropractors were not coming in and not coming before the board. I do not think that is true. If a chiropractor goes into a town some medical practitioner who is beside him will report him, an osteopath particularly will do that because the chiropractor encroaches more on the osteopath's ground than on the general practitioner's. I hardly think one would find twelve chiropractors unlicensed that have come in since 1927.

DR ARTHUR C. MORRAN, Philadelphia. Name the six subjects in basic science.

DR LEHNHOFF. Anatomy, pathology, chemistry, physiology, hygiene and bacteriology.

DR MORRIS. If a medical student passes the basic science board does the medical board then make him take the examination in the same six subjects again?

DR LEHNHOFF. We are supposed to.

DR MORRIS. You mentioned that your standard was 75 per cent and the other was 60 per cent. How could he pass one without passing the other one?

DR LEHNHOFF. I think the law reads that we should examine him. It was not the intention of the framers of the

law that we should reexamine him, and we had quite a problem among ourselves. We do not require candidates to take all the examinations over. After they are passed on by the basic science board the questions are passed over to us and we pass on the examinations that are written before the basic science board.

DR H M PIATTER, Columbus Ohio. Mr Chairman you referred to me and Dr Hassig the resolution prepared by Dr Crowe. We have tried to edit it, and we submit the following:

WHEREAS Persons who have been prohibited from broadcasting misleading medical propaganda over radio stations in the United States are now making such misrepresentations in the English language from stations in northern Mexico and

WHEREAS One of said broadcasters not a physician knowing that one nearing death with an incurable disease will travel thousands of miles and give his last penny for anything offering the faintest hope of cure is boldly broadcasting the preposterous statement that his hospital cures 70 to 75 per cent of internal and of external cancers even after they had been pronounced incurable by prominent physicians and surgeons and

WHEREAS His utterly absurd reports on the cure of cancer are positively refuted by verified certifications of death due to cancer of a large number of persons within a few months after having been reported cured at this man's hospital therefore be it

Resolved That the Federation of State Medical Boards representing the licensure authorities of the United States deplores that an enlightened humane nation permits such broadcasters to prey on suffering human beings sending him or her away to die sometimes before reaching home. Believing that if the pitiful results of such broadcasting were known to the Mexican government its conscientious executives would stop it the Federation hereby respectfully earnestly petitions the Departamento de Salubridad Publica the Departamento de Comunicaciones the Medical Syndicates and the scientific medical profession of Mexico to cooperate with the reputable medical profession of the United States in its effort to put a stop to the merciless exploitation of helpless suffering incurables.

DR CROWE I had Dr Brinkley in the courts of Dallas and would have taken his license away from him but the courts of Texas years ago decided that a man might have two places of residence one his place of business and the other his domicile. Consequently my case was transferred to Valverde County. Here is Valverde County. Look at XER. Greetings from the chamber of commerce churches schools, municipal government, power plant banks and trust companies. They told me they did not care what he does he put them on the map and they were for him. Look at this one issue of a paper. That belt cost \$2,500. It cures everything from falling hair to fallen arches. They do not sell it for \$2,500. They lease it to you for a certain time but they make you deposit with them \$2,500 for its safe return, and they never come back. Here is a check for \$1,045. There is one for \$1,250 and there is one for \$875, and two others boosted the amount to \$7,400. For what? For the pretended removal of cataract. I have a basketful of these checks. I brought just a few to show you. We got rid of these fellows but they are coming to your country. We were the last state in the Union to license optometrists. They went around the country and sold farmers glasses. A number of those men are reputable but there are a lot of them that are crooks. This man here was in the Rice Hotel dining room, and he had 300 people to whom he was going to teach brain breathing. Our man got there and told him that if he got up on that platform to lecture he would spend the night in jail. He did not get on the platform. These fellows do not come to Texas any more. I told Levine he was a swindler and he called me a liar. I knocked him down and took him to the grand jury. We are protecting the public, trying to do the best we can. Is that work worth while? It is not costing the state of Texas one penny. It is costing the doctors of Texas an annual registration of \$15,000 a year to do that. We save almost that much in two or three days. I sent a man by plane to Houston to get these two fellows. We do not have to run around for a police officer. We do not nambu-pambu them in Texas. I wanted you to know that you can do things if you want to but you have got to do them yourself, because if you let George do it they will not be done.

DR METZGER If we can get Dr Crowe to come to our states and show us his demonstrations, I am sure it will make us do better work along that line.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

### ALABAMA

**Personal**—Dr Charles Jack Fisher has resigned as house physician at St Vincent's Hospital Birmingham, to become head of the Lawrence County Health Department, effective April 1, it is reported.

**Meeting of Clinical Society**—The twenty fifth annual clinic and nineteenth annual meeting of the John A. Andrew Clinical Society was held at the John A. Andrew Memorial Hospital April 5-11. In addition to the many clinics held on the specialties, the following physicians, among others presented papers:

John T. Givens, Norfolk, Va., The Sedimentation Rate in Practice  
Toussaint T. Tildon, Tuskegee, Cardiovascular Disease Among the Neurosyphilitic  
Seale Harris, Birmingham, Blood Chemistry Studies in Automobile Accidents with Particular Reference to Drinking Drivers  
Trygve Gundersen, Boston, Diagnosis and Treatment of Corneal Diseases  
Walter C. Crump, New York, Rationale in Appendicitis  
Marion C. Pruitt, Atlanta, Ga., Rectal Fistula  
William L. Funkhouser, Atlanta, Ga., Vomiting as a Symptom in Infancy and Childhood

A public health meeting was held Monday evening this session has been established as a permanent memorial to the late Dr Charles V. Roman, the first president of the society. Thursday evening a symposium on genito-urinary diseases was held with the following speakers: Drs. Vance S. Mullan, Chicago; Chester C. Ames, Detroit; Charles H. Garvin, Cleveland; Robert Francis Jones, Washington, D. C.; and Walter S. Grant, Chicago.

### CALIFORNIA

**Society News**—Dr Frank S. Dolley, Los Angeles addressed the San Diego County Medical Society, April 3 on 'Diagnosis and Surgical Treatment of Bronchiectasis and Intrathoracic Tumors'. At a joint meeting of the Los Angeles County medical and dental associations, April 16 David W. McLean, D.D.S., among others discussed 'Mechanical Causes of Dental Pathology,' and Dr Samuel J. Glass 'Endocrine Aspects of Some Dental Abnormalities'.

**Survey of Student Health**—Students entering the University of California and Leland Stanford University in the fall of 1935 are to be the subject of a ten year study, according to the Bulletin of the National Tuberculosis Association. The physical histories of these students which number about 5,000 will be kept in the two universities. Follow up records will be kept following graduation. A permanent research committee has been established with representatives of all supporting tuberculosis associations participating together with representatives of the student health services in the universities and a research adviser. The expense of the research is to be borne by the regional tuberculosis associations and by the institutions cooperating.

### DISTRICT OF COLUMBIA

**The Harvard Conference of Arts and Sciences**—The Harvard tercentenary conference of arts and sciences will be held at Harvard University, Boston August 31-September 12. World leaders in the physical, biologic and social sciences and the humanities will discuss the fundamental problems of science and society rather than the particular aspects of applied learning. Fourteen winners of the Nobel Prize will be on the program together with representatives of Europe, the United States, Japan, China, Argentina, Canada and Australia. The extensive program includes the following speakers:

Leopold Ruzicka, professor of chemistry, Technische Hochschule Zurich  
The Male Sex Hormones  
Dr. Karl Landsteiner of the Rockefeller Institute for Medical Research  
New York. Serologic and Allergic Reactions with Simple Chemical Compounds  
Dr. Kiyoshi Shiga, professor of medicine, University of Tokyo. Trend of Prevention Therapeutics and Epidemiology of Dysentery Since the Discovery of Its Causative Organism  
Dr. Ross Granville Harrison, professor of biology, Yale University  
School of Medicine, New Haven, Conn. Relations of Symmetry in the Developing Embryo  
Hans Spemann, Ph.D., professor of zoology, University of Freiburg (title not yet announced)  
Sir Joseph Barcroft, professor of physiology, University of Cambridge  
The Genesis of Respiratory Movements in the Fetus  
Sir Frederick Gowland Hopkins, professor of biochemistry, University of Cambridge (title not yet announced)  
Dr. Bernardo Alberto Houssay, professor of physiology, University of Buenos Aires (title not yet announced)

Symposiums to be presented include one on the applications of physical chemistry to biology by Schack August Steenberg Krogh, Ph.D., professor of zoological physiology, University of Copenhagen, John Howard Northrop, Ph.D., of the Rockefeller Institute for Medical Research, Theodor Svedberg, D.Sc., professor of physical chemistry, University of Uppsala and Dr. Otto Warburg of the Kaiser Wilhelm Institute for Cell Physiology, Berlin. A symposium on factors determining human behavior will be offered by

Dr. Edgar Douglas Adrian Foulerton, professor of the Royal Society  
Dr. Pierre Marie Felix Janet, professor of psychology, College of France  
Dr. Carl Gustav Jung, professor of analytic psychology, Technische Hochschule Zurich  
Jean Piaget, professor of the history of scientific thought, University of Geneva  
Dr. James Bertram Collip, professor of biochemistry, McGill University  
Rudolf Carnap, professor of philosophy, Deutsche Universität Prague  
Abbott Lawrence Lowell, LL.D., president emeritus, Harvard University  
Bronislaw Malinowski, professor of anthropology, University of London

## MICHIGAN

**Committee Confers with Governor on Relief**—At a meeting of a committee of the Michigan State Medical Society, March 18, Governor Frank D. Fitzgerald stated that he intends to appoint a commission to outline legislation designed to revamp and coordinate all state relief agencies and to see that the medical profession is represented on it. Through the committee, the state society offered the services and cooperation of the medical profession in settling these problems.

**Integration Program of State Society**—The Michigan State Medical Society announces an "integration program" as a part of a five year program to coordinate its activities. According to the program the society is represented as a group of central committees whose energies will be directed to evolution of plans, policies and objectives. Plans and policies directly concerned with the conditions represented by their specific designation such as legislation, economics or health, will be evolved independently of any other committee to be transmitted to the council or its executive committee for its approval. The projects will then be passed on to the public relations committee for consideration as to their worth to the councilor districts, the county societies and the individual physician. Following the report of the public relations committee to the council or executive committee, approved projects will be disseminated by the public relations committee to the medical profession through the councilors, the public relations committee or its equivalent in the county society, the individual physician and the public. The object of the new plan is to

have every doctor at all times acquainted with the plans, policies and objectives of the state society and to have a consistency of thought and action, as far as possible, among the membership.

## MISSISSIPPI

**State Medical Meeting at Greenville**—The sixty-ninth annual session of the Mississippi State Medical Association will be held at the Hotel Greenville in Greenville, May 5-7, under the presidency of Dr. James R. Hill, Corinth. Guest speakers will include the following physicians:

Fred W. Rankin, Lexington, Ky., Symptoms and Prognosis of Organic Diseases of the Lower Gastrointestinal Tract  
James B. Stanford, Memphis, Modern Ophthalmology  
Harold L. Warwick, Fort Worth, Ionization in Nasal Allergy  
Alvin E. Keller, Nashville, An Evaluation of the Clinical Manifestations of Hookworm in Children  
Frank J. Heck, Rochester, Minn., Practical Treatment of Anemia.

Tuesday evening, Dr. Hill will deliver his presidential address, among others, on "Some Accomplishments of Organized Medicine in Mississippi," and Dr. Morris Fishbein, Chicago, editor of THE JOURNAL, will present the Ewing Fox Howard Oration on "Medicine and the Changing Social Order." Other physicians on the program include:

Willard H. Parsons, Vicksburg, Fractures of the Upper End of the Femur with Particular Reference to Their Treatment  
Theophilus E. Ross, Jr., Hattiesburg, Inguinal Hernia  
Thomas P. Sparks, Jr., Vicksburg, Renal Lithiasis  
John W. Barksdale and Nathan F. Kendall, both of Jackson, Use of Radium in Carcinoma of the Cervix  
Edwin E. Benoist, Natchez, Maintenance of Relative Asepsis in Abdominal Surgery  
John C. Culley and James R. Sims, Jr., Oxford, Anesthesia in Obstetrics and Obstetric Complications  
Hubert Lowry Rush and Leslie V. Rush, both of Meridian, Spina Bifida  
Adna G. Wilde, Jackson, Clinical Significance of Episcleeritis  
DeWitt Hamrick, Corinth, Tonsillectomy, Indications, Methods, Results  
Vernon B. Harrison, Holly Springs, Management of Syphilis from a Public Health Standpoint  
John W. Shackelford, Greenville, Poliomyelitis, A Review of Recent Literature  
Norris C. Knight, Barksdale, Laboratory Aids in the Diagnosis of Communicable Diseases  
John F. Lucas, Greenville, Prevention and Treatment of the Late Toxemias of Pregnancy  
Leon S. Lippincott, Vicksburg, Blood Chemistry in Kidney Disease  
Van C. Temple, Hattiesburg, Asphyxia in the New Born  
Walter E. Johnston, Vicksburg, Arthritis  
Carl O. Singly, Meridian, Some Common Fungus Diseases of the Skin  
Robin Harris, Jackson, Sinus Disease and Nasal Allergy.

The women's auxiliary to the state association will also convene at this time; speakers will include Dr. Hill, Dr. Harvey F. Garrison, Jackson, and Dr. Fishbein. The seventh annual meeting of the Mississippi State Hospital Association will be held at the Hotel Greenville, May 4; speakers will include Dr. Bert W. Caldwell, executive secretary, American Hospital Association, Chicago, on "Modern Trends in Hospitalization," and Dr. Neal N. Wood, Birmingham, Ala., "Common Methods of Sterilization."

## MISSOURI

**Personal**—The following St. Louis physicians observe their fifty-fifth anniversary of graduation from the St. Louis Medical College at a reunion, March 4: Max C. Starkloff, Willis Hall, Amand N. Ravold and James A. Dickson.

**Society News**—The St. Louis Medical Society acted as host to the interns of St. Louis hospitals at its meeting, March 10; the program was presented by the following interns among others: Ewing Selgman, "Hematemesis Following Cholecystectomy," and Jesse Norris Tucker, Jr., "Polyneuritis Following Hyperemesis Gravidarum." Dr. Dallas B. Phemister, Chicago, discussed "Bone Tumor Problems" before the society, March 12. Speakers before the Marion Ralls County Medical Society in Hannibal, March 6, were Drs. Walter Baumgarten and Fred W. Bailey, St. Louis, on "Hypertension" and "Surgical Care of Gallbladder Diseases," respectively. At a meeting of the St. Louis County Medical Society, March 25, Dr. Richard S. Weiss discussed "Precancerous Dermatoses," and Dr. Louis H. Jorstad, Cancer of the Lip and Buccal Cavity.

## MONTANA

**Physician Honored**—Dr. Joseph Pedalue, Bozeman, was guest of honor at a banquet, April 2, given by the Gallatin County Medical Society in recognition of his completion of fifty years in the practice of medicine in Montana. Dr. Pedalue was made an honorary life member of both the county society and Medical Association of Montana and was presented with a book and flowers. Sixteen years of his career has been spent as health officer of Bozeman and Gallatin County.

## NEW MEXICO

**Child Welfare Extended with Federal Funds**—Six new offices have been opened by the bureau of child welfare of the state bureau of public health to extend child welfare services through a grant of funds under title V of the Social Security Act which is administered by the Children's Bureau. With the present state appropriation the bureau has maintained offices at Santa Fe and Albuquerque.

## NEW YORK

**Dr Baldwin Awarded Kober Medal**—Dr Edward Robinson Baldwin, director of the Edward L. Trudeau Foundation, Saranac Lake, will be presented with the Kober Medal at the annual meeting of the Association of American Physicians in Atlantic City, May 6. The medal is awarded each year by the association on the recommendation of its council. Dr Baldwin graduated from Yale University School of Medicine in 1890 and has been practicing at Saranac Lake since 1893. Among other things he was president of the Saranac Lake board of health from 1899 to 1901 and from 1916 to 1917 president of the National Tuberculosis Association.

**Dr Godfrey Nominated State Health Officer**—Dr Edward S. Godfrey Jr., assistant state health commissioner, was nominated April 6 by Governor Lehman as commissioner to succeed Dr Thomas Parran Jr. who became surgeon general of the U. S. Public Health Service. Dr Godfrey, a graduate of the University of Virginia Department of Medicine served as health officer in Arizona for several years. He joined the New York department in 1917 as a sanitary supervisor under the late Dr Hermann M. Biggs. Later he served as epidemiologist and in 1931 was appointed director of local health administration. In 1934 he received the title of assistant commissioner in charge of the bureau of local health administration. Dr Godfrey was clinical professor of epidemiology at Columbia University College of Physicians and Surgeons from 1928 to 1935 and has been president of the American Epidemiological Society. He has been secretary of the Public Health Council since 1932.

## New York City

**Progress of Hospital Plan**—The Associated Hospital Service of New York, a group plan for financing hospital care, has enrolled 66,095 members in the first ten months of its operation. The plan represents 174 hospitals in the metropolitan area.

**Personal**—James Thomas Culbertson, Ph.D., instructor in bacteriology, Columbia University, has received a fellowship from the John Simon Guggenheim Memorial Foundation for study of immunity against parasitic diseases at the London School of Hygiene and Tropical Medicine. Michael Heidelberger, Ph.D., associate professor of biologic chemistry at Columbia, received a renewal of a grant for study of immune reactions.

**WPA Seeks to Employ Handicapped**—The Works Progress Administration has opened a bureau for the physically handicapped. Cardiac cases and persons with arrested cases of tuberculosis are included in the classification as well as the orthopedic and other cases commonly associated with the term. Figures issued by the home relief bureau showed about 12,000 physically handicapped on the relief rolls, 5,000 of whom are classified as employable.

**Hospital News**—Dr Roger Anderson, Seattle, gave a special afternoon lecture at the New York Polyclinic Medical School and Hospital March 20 on "An Anatomical or Non-operative Method of Treating Fractures of Both Bones of the Forearm and Ambulatory Method of Treating Fractures of the Femur." At a recent meeting of the clinical society of the school Dr Archibald D. Campbell, Montreal, Que., and George W. Crile, Cleveland, spoke on "The Present Status of Endocrine Therapy in Gynecology" and "The Genesis and Surgical Treatment of Hypertension" respectively. A meeting in commemoration of the late Professor Pavlov was held at

Mount Sinai Hospital, March 24. Speakers were Drs. Boris P. Babkin, Montreal, on "I. P. Pavlov: His Life and Work," and Howard S. Liddell, Ph.D., Ithaca, N. Y., "Pavlov: the Psychiatrist of the Future."

**Society News**—A symposium on psychiatry was presented before the International and Spanish-Speaking Association of Physicians, Dentists and Pharmacists March 20, by Drs. Eugen Kahn, New Haven, Conn., Karl M. Bowman, George W. Henry and Gerard L. Moench—Clarence C. Little, Sc.D., managing director of the American Society for the Control of Cancer, and Dr. William J. Hoffman addressed the Medical Society of the County of Queens March 31 on "Cancer and the Present Status of the Campaign for Cancer Control and Present-Day Treatment for Cancer" respectively. Dr. Frank A. Pemberton, Boston, addressed the Queensboro Surgical Society, April 29, on "Tumors of the Ovary." Dr. Richard B. Cattell, Boston, addressed the Bronx County Medical Society, April 15 on "Tumors of the Gastro-Intestinal Tract—Diagnosis and General Principles of Treatment." Speakers before the Bronx Gynecological and Obstetrical Society, April 27, included Drs. Harry Projector on "Multiple Fibroids Complicating Pregnancy," and Jacob Clahr, "Corpus Luteum Abscess." At a meeting of the Medical Society of the County of New York April 20, Dr. Arthur M. Master, in collaboration with Drs. Harry L. Jaffe and Simon Dack presented "A Study of 250 Attacks of Coronary Artery Thrombosis: Treatment, Course and Prognosis of the Attack" and Dr. Edward F. Bland, Boston, "Subsequent Course of 400 Patients Following Coronary Thrombosis: A Study in Prognosis."

## NORTH CAROLINA

**State Board Meeting**—The North Carolina State Board of Medical Examiners announces a meeting June 15 at the Sir Walter Hotel, Raleigh. Applications for endorsement of credentials will be considered during the morning. Registration for examinations will take place at 2:30 p. m. and examinations will be held the following morning and thereafter through Friday, June 19. Each applicant in order to register must possess an M.D. degree and he must have his diploma with him, together with two letters of recommendation. Applicants for the first two year examinations must be certified by their respective deans as having completed all the first two year subjects successfully.

**State Medical Meeting at Asheville**—The eighty-third annual session of the Medical Society of the State of North Carolina will be held at the Battery Park Hotel Asheville, May 4-6 under the presidency of Dr. Paul H. Ringer, Asheville. Among many other physicians the following will speak on the subjects indicated:

Milton J. Rosenau, Chapel Hill, Pneumonia  
Irvin Abell, Louisville, Ky., Relation of Diabetes to Surgery  
Albert McCown, Washington, D. C., Educational Program for Pediatricians  
James S. McLester, Birmingham, Ala., President American Medical Association  
Isidor S. Ravdin, Philadelphia, Certain Aspects of Gallbladder Disease  
Clarence C. F. Cardner, Jr., Durham, Hyperparathyroidism—Its Recognition and Treatment  
Julian A. Moore, Asheville, Surgical Treatment of Encapsulated Intrathoracic Tumors  
Carl V. Reynolds, state health officer, Raleigh, Poliomyelitis in North Carolina in 1935  
James M. Northington, Charlotte, Is Public Health Impinging on Private Practice?

The women's auxiliary will meet, May 4-6 and the North Carolina Public Health Association will hold its twenty-sixth annual session Monday, May 4. Speakers will include Dr. James A. Hayne, Columbia, state health officer of South Carolina, "Columbia on Maternal and Child Health—Why Should the Maternal and Child Death Rate Be So High in the South and What Remedies Are We Going to Apply?"

## OHIO

**Symposium on Virus Diseases**—At the annual meeting of the Ohio Academy of Sciences at the University of Toledo April 10 a symposium on virus diseases was presented at a joint session of the sections on zoology and medical sciences arranged by Dr. Charles A. Doan, Columbus. Among the speakers were Dr. Noel Paul Hudson, Columbus, on "Factors of Resistance and Immunity in Poliomyelitis," Dr. James A. Doull, Cleveland, "Epidemiologic Considerations in the Field of Virus Diseases with Special Reference to the Common Cold and Influenza," and Joseph T. Tamura, Ph.D., Cincinnati, "Cultivation of and Immunological and Clinical Studies with the Virus of Lymphogranuloma Inguinale."

**Society News**—Dr. Elliott P. Joslin, Boston, addressed the Academy of Medicine of Cincinnati April 14 on diabetes under the joint auspices of the academy and the committee on diabetes.

of the Public Health Federation of Cincinnati—Dr Richard H. Jaffe, Chicago, addressed the Summit County Medical Society, Akron, April 7, on 'Significance of the So Called Pre-cancerous Lesion'. Ro, Seattle, addressed the King County Medical Society, April 20 on "Sacculated Varix of the Femoral Vein" and "Cool Water Treatment of Burns" respectively.—Dr Howard L. Beve, professor of surgery, State University of Iowa, College of Medicine, Iowa City, addressed the annual meeting of the Tacoma Surgical Club on "Surgical Pitfalls and Their Prevention."

### WEST VIRGINIA

**Hospital News**—The Pinecrest Sanitarium, Beckley, has under construction a nurses' and physicians' home to accommodate forty nurses and two physicians with their families. The new building will cost \$82,000, provided from federal funds. Other projects at the sanatorium include barns to cost about \$38,000 and other improvements to cost \$23,000.

**Society News**—Dr Austin A. Hayden, Chicago, addressed the Cabell County Medical Society, Huntington, March 12 on medical economics.—Drs. Eldon B. Tucker, Morgantown, and Herbert H. Haynes, Clarksburg, addressed the Harrison County Medical Society, Clarksburg, March 5, on 'Present Status of Anesthesia in West Virginia' and "Carcinoma of the Rectum" respectively.—Dr Claude C. Coleman, Richmond, Va., addressed the Kanawha Medical Society, Charleston, March 10 on 'The Present Scope of Neurological Surgery'.—Dr John H. Wickoff, New York, addressed the Parkersburg Academy of Medicine, March 5, on "Congestive Heart Failure."

### GENERAL

**Date Changed for Public Health Meeting**—The American Public Health Association will hold its sixty-fifth annual meeting in New Orleans, October 20-23, instead of October 19-22 according to the *American Journal of Public Health*.

**Change in Date of Orthopedic Examination**—The date of the examination to be held by the American Board of Orthopaedic Surgery is changed from Monday, May 11 to Tuesday, May 12. The examination will be held at St. Luke's Hospital, Forty-Fourth Street and Mill Creek Parkway, Kansas City, at 9 a. m.

**Academy of Pediatrics**—The sixth annual meeting of the American Academy of Pediatrics will be held at the President Hotel in Kansas City, Mo., May 11-12. Monday morning will be devoted to round table discussions of asthma, childhood psychiatry, diagnosis of appendicitis in children, intestinal parasitic infections, passive prophylaxis against infection in childhood, physical appraisal of the child, prophylaxis and treatment of whooping cough, recent advances in nutrition, roentgenology of the thorax in children, sinusitis—indications for treatment, and treatment of the overweight child. There will be panel discussions in the afternoon on the problem of immunity to tuberculosis in childhood and cyanosis in the newborn. The evening meeting of state chairmen, Monday, will be devoted to a consideration of graduate education in pediatrics. Dr. John A. Toomey, Cleveland, will address the general meeting Tuesday on 'The Gastro-Intestinal Portal of Entry in Poliomyelitis'. and Drs. Richard Cannon, Elev., and Charles F. McKhann, Boston, 'The Clinical Application of the Blood Coagulant Extract Obtained from the Human Placenta'.

**Medical Bills in Congress**—Changes in Status. The House conferees on the War Department Appropriation Bill, H. R. 11035, have accepted the Senate amendment to the bill providing for the reestablishment of medical units in the Reserve Officers Training Corps. S. 4390 has been reported to the Senate, with amendment proposing to amend the National Defense Act relating to the Medical Administrative Corps so as to provide that appointments to the corps shall be restricted to pharmacists between the ages of 21 and 32 years who are graduates of recognized schools or colleges of pharmacy requiring four years of instruction for graduation and to provide that the number of such appointees shall not exceed sixteen. **Bills Introduced** S. 4508, introduced by Senator Byrne, South Carolina, proposes to provide a uniform rate of pension for unmarried Spanish-American War veterans without dependents while hospitalized and to extend hospitalization to per

sons recognized as veterans of the Spanish-American War under laws in effect prior to March 20, 1933 S 4516 introduced (by request) by Senator Robinson, Arkansas and H R 12460, introduced (by request) by Representative Driver, Arkansas, propose to authorize appropriations of \$5,000,000 and \$15,000,000, respectively, to enable each state to provide and operate at least one hospital bed for tuberculous patients to each annual death from tuberculosis in the state

**Safety Conference**—The fourteenth annual Midwest Safety Conference will be held at the Stevens Hotel, Chicago, May 57, under the auspices of the Chicago Safety Council, Illinois Industrial Commission, Keep Chicago Safe Committee and cooperating agencies Consideration will be given to fire prevention, the commercial vehicle, home safety, safety in handling materials, first aid, public safety, training and educational methods, occupational diseases, and safety equipment Speakers will include

George W Barton manager highway traffic department Chicago Motor Club Chicago Driver Tests—Their Uses and Limitations in the Commercial Vehicle Field

D Melville Carr director accident prevention service Chicago chapter American Red Cross Chicago Home Accidents—A National Problem

Dr Hart E Fisher chief surgeon Chicago Rapid Transit Company Chicago Personal Experience of the Value of First Aid Training in a Large Utility

Dr Royd R Sayers director industrial hygiene department U S Public Health Service Washington D C What the Industrial Executive Should Know About Occupational Diseases

Dr Clarence O Sappington consulting industrial hygienist Chicago Proper Type Use and Maintenance of Respiratory Protective Devices

**Society News**—The American Pharmaceutical Association will hold its annual meeting in Dallas, Texas, August 24-29—The American Neisserian Medical Society will hold its second annual meeting, May 18 at the Hotel Statler, Boston Dr Hans Zinsser, Boston will be the guest speaker his subject, "To What Extent Can a Bacteriologist Contribute to the Control of Venereal Diseases?"—The sixth annual meeting of the Biological Photographic Association will be held in Boston about September 17—Dr Alphonse R Dochez New York was named chairman of the executive committee of the Federation of American Societies for Experimental Biology at the annual meeting in Washington, and Dr Shields Warren, Boston, secretary Memphis, Tenn, was chosen as the city for the 1937 convention Officers elected by the American Society of Biological Chemists included Howard B Lewis, Ph D, Ann Arbor, Mich president and Henry A Mattill Ph D, Iowa City, secretary The American Society for Experimental Pathology elected Dr Dochez president and Dr Warren secretary Dr Frank C Mann, Rochester, Minn, was named president of the American Physiological Society, and Dr Andrew C Ivy, Chicago secretary Dr Velyien E Henderson, Toronto, Ont, was elected president of the American Society for Experimental Pharmacology and Therapeutics and Dr Eugene M K Geiling, Chicago, secretary—The American Association of Obstetricians, Gynecologists and Abdominal Surgeons will hold its annual meeting at the Hotel Washington Bretton Woods, N H, September 14-16 Dr James R Bloss, 418 Eleventh Street, Huntington, W Va, is the secretary

**The Woman's Auxiliary**—The March News-Letter of the Woman's Auxiliary to the American Medical Association is the Southern States number, reporting the activities of twelve organized southern states The Arkansas auxiliary has stressed promotion of annual physical examinations and other phases of health education Georgia sponsors a health education program on child psychology and heart disease The principal interest of the Kentucky auxiliary is its Jane Todd Crawford Memorial Project this organization, among many other kinds of work, has made a special study of tuberculosis and cancer Louisiana's auxiliary sponsors health education in cooperation with public schools such as essay contests and projects in which *Higiena* is used Mississippi is devoting its efforts this year to promotion and endowment of the preventorium at the Mississippi State Sanatorium North Carolina women maintain a bed at the North Carolina State Sanatorium called the McCam bed in honor of Dr and Mrs Paul P McCam, superintendent of the sanatorium, and his wife The bed is kept for the use of physicians and their families In Oklahoma the state auxiliary has furnished material to high school students for the debate on state medicine and several members have acted as judges South Carolina is placing special emphasis on its student loan fund for the use of physicians sons and daughters who lack money for medical courses Tennessee emphasized public relations and did much philanthropic work Public education is a major responsibility of the Texas auxiliary Alabama has carried out a program of public relations and health education and has a legislative program Florida has cooperated in state

programs on cancer control and heart disease and has made contacts with parent-teacher's associations In addition to special activities, many states have student loan funds and funds for indigent physicians, several have sponsored a "doctors day" all publicized the American Medical Association radio program during the winter, all did much philanthropic work, both independently and in cooperation with tuberculosis associations and the Red Cross, and many are preserving local medical history

### Deaths in Other Countries

Josef Jadassohn, for many years professor of dermatology at the University of Breslau, Germany, died, March 24 in Zurich, Switzerland, aged 72 Professor Jadassohn contributed to numerous textbooks and was an editor of various periodicals Among other important publications was his "Handbuch der Haut- und Geschlechtskrankheiten"—Friedrich Kraus died in Berlin recently Dr Kraus in 1894 was made professor in Graz and chief of the medical clinic In 1902 he succeeded Gerhard as chief of the second medical clinic of the Charite in Berlin, holding this title until 1926, when he was made emeritus

## Government Services

### Social Security Grants Totaling \$5,000,000

The Social Security Board announces allotments of federal funds totaling \$5,293,876 for grants-in aid to eight states with approved public-assistance plans These grants will match the states' expenditures for assistance to their needy aged, needy blind, and dependent children The states sharing in grants for April, May and June and the amounts authorized are as follows

State	For Assistance to	Federal Grant
Minnesota	Aged	\$ 721 875 00
Massachusetts	Aged	1 026 712 00
Oklahoma	Aged	433 427 00
Connecticut	Aged	221 812 00
Vermont	Aged	74 498 00
New Mexico	Aged	83 396 00
New Mexico	Blind	13 868 00
Oklahoma	Dependent children	154 422 67
New Mexico	Dependent children	24 327 50
<b>Total</b>		<b>\$2 754 338 17</b>

The board also announced the mailing of checks to the following states as grants-in-aid for their public assistance work during February and March

State	For Assistance to	Federal Grant
Ohio	Aged (for Feb and March)	\$1 611 875 00
Minnesota	Aged (for March)	105 000 00
Arkansas	Aged (for March)	78 400 00
Massachusetts	Aged (for Feb and March)	651 014 00
Utah	Aged (for March)	66 213 00
Utah	Blind (for March)	5 607 00
Utah	Children (for March)	19 548 00
Vermont	Children (for March)	1 881 00
<b>Total</b>		<b>\$2 539 538 00</b>

In the case of aid to the needy aged and blind, the federal grant matches the states' expenditures dollar for dollar up to a combined total of \$30 per month per person and also includes 5 per cent additional for the states administrative expenses In the case of aid to dependent children, the federal government pays \$1 for every \$2 disbursed by the states up to a combined total of \$18 per month for the first dependent child in a family and \$12 per month for each additional dependent child The federal government also pays one third of the states' administrative costs for this form of public assistance

To date thirty states and the District of Columbia have submitted public assistance plans which conform with the requirements of the Social Security Act, and these states are participating in the cooperative state federal system of aid provided by the act Among these are twenty-eight approved state plans for aid to the needy aged, eighteen approved state plans for aid to the needy blind, and seventeen approved state plans for aid to dependent children It is estimated that they provide assistance to approximately 500 000 aged individuals, 125 000 dependent children and 17 000 blind persons The federal contribution toward the care of these persons in all states whose public-assistance plans have been approved by the Social Security Board is expected to be more than \$14,000 000 for April May and June

#### Annual Report of Medical Research

The report of the Medical Research Council for 1934-1935, which has just been published contains a review of recent researches that the council has supported

#### NUTRITION

The council initiated research on rickets, which led to the discovery and isolation of vitamin D. It supported work on the dietetic factors that determine the production of perfect or imperfect teeth, as a result of which it is now practicable to improve greatly the structure of the teeth of the rising generation by proper feeding in childhood. It is responsible also for clinical investigations which showed that apart from dental structure decay of teeth can be slowed by diet.

#### THE DIET OF GROWING CHILDREN

One of the most practical investigations initiated by the council showed the effect of supplementing the diet of growing children with milk and other substances. In a carefully controlled test on children in institutions the addition of a pint of milk daily to what had been regarded as an adequate diet produced surprising benefits in height, weight, mental activity and general health.

#### ISOLATION OF ERCONOVINE

During the last thirty years, investigations have shown that ergot contains not one but a series of active principles. Early in 1935 a new alkaloid was isolated by a joint investigation of H. W. Dudley and J. C. Moir. It has been shown that this principle is mainly responsible for the obstetric value of ergot. Previous researches on the active principles of ergot showed a disparity between pharmacologic and clinical practice and some skepticism arose as to the value of watery extracts. When in 1932 Moir used a method for obtaining a quantitative record of the contractions of the puerperal human uterus it was at once clear that a watery extract administered by the mouth evoked vigorous contractions. This stimulant effect lasting for some hours was not produced by any of the known constituents of ergot or by any other known substance.

#### THE CURATIVE AGENT OF PERNICIOUS ANEMIA

During the past year Dakin and West published in America a method for preparing the active hematopoietic agent from liver in a much purer state than was formerly possible. This substance is a complex protein structure made up of amino acids and other groups. During the summer Dr. Dakin came to England and supervised the preparation on a manufacturing scale of hematopoietic liver extract principles. At the invitation of the council Professor Davidson, Prof. E. J. Wayne and Dr. C. C. Ungley tested this substance in cases of pernicious anemia and found it extremely potent. The effect of the liver treatment is shown in the official statistics of the death rate from pernicious anemia by a great fall up to the age of 65 after this age and especially by the age of 75 the rate has greatly increased.

#### THE PREVENTION OF PUERPERAL FEVER

It has long been known that a streptococcus which hemolyzes red corpuscles is responsible for most cases of puerperal sepsis but it has been recognized only in the last few years that the cocci with this property comprise several groups which are associated with other diseases such as scarlet fever, acute tonsillitis, erysipelas, whitlow, impetigo, wound infection and perhaps acute rheumatism. New technical procedures developed

at the Rockefeller Institute, New York, for the differentiation of the hemolytic streptococci have enabled workers at Queen Charlotte's Hospital, London, to reach the conclusion that the hemolytic streptococci occasionally found in the genital tract of healthy parturients are not, as was supposed, identical with those causing puerperal fever, and that they are indeed usually harmless. This suggests that pathogenic hemolytic streptococci which invade the genital tract have been conveyed from some outside source. In a large series of cases Dr. Dora Colebrook has traced these outside sources. She has shown that the streptococci of the respiratory tract have an intimate relation to puerperal fever. But the respiratory tract of the mother must be taken into account as well as that of her attendants, and familial sources have been incriminated in not a few instances. It is therefore dangerous for any person suffering from an acute infection of the respiratory tract to engage in maternity work. It is also unwise for nursing homes and small hospitals to deal with maternity and surgical cases under the same roof unless the nursing staffs of the two departments can be completely separated.

#### New Research Body for Tropical Medicine

The establishment of a tropical medicine research committee is announced. The decision to appoint this body has been taken by the Medical Research Council in consultation with the Colonial Office. The new committee will advise and assist in the direction of such investigations as the council may be able to promote, into problems of health and disease in tropical countries, and make suggestions generally as to research in this field. The committee will be a purely scientific body and will include representatives of the Colonial Office and of the London and Liverpool Schools of Tropical Medicine with others appointed as individual experts in tropical medicine or other branches of medical science. The following men will serve in the first instance: Prof. J. C. G. Ledingham, FRS (chairman), Prof. A. J. Clarke, FRS, Prof. W. W. Jameson, Edward Mellanby, FRS, Sir Leonard Rogers and Dr. C. M. Wenyon, FRS. Research in tropical medicine has always been a concern of the Medical Research Council but this has usually been performed in England. The council has not been able to assist investigations in the tropics except on isolated occasions. The present step indicates an intention to take a more active part in work in the colonial field.

#### The Subintoxicated Driver

In the house of commons a medical member, Dr. Alfred Salter, called attention to the danger of automobile drivers taking any alcoholic drink whatever. This point has previously been brought forward but not emphasized sufficiently. Dr. Salter said that all agreed that the intoxicated driver should be severely dealt with, but there was a greater danger of the subintoxicated—the man who was not drunk in the legal sense but was physiologically under the influence of alcohol. The minister of transport had expert advice on this matter, at his own request, but had done nothing to bring to the attention of the motorists the danger of taking any alcohol before or during driving. A committee of the British Medical Association came to the conclusion that there were serious objections to the consumption of alcohol in quite small amounts by any one who had to drive a car. At least 25 per cent of road accidents were due to the fact that the drivers had consumed small quantities of alcohol. They were not intoxicated but, as the British Medical Association said, subintoxicated. In an editorial the *Times* said: 'As things stand at present there would appear to be no absolute safeguard for the motor driver but total abstinence.'

In replying to the debate the minister of transport, Mr. Horc Belisha, said that traffic congestion was greater here than in any other country. The number of automobiles registered

to the square mile in Great Britain was twenty-three, in the United States it was seven. In regard to alcohol he identified himself with the view of the British Medical Association that there were serious objections to drivers taking even the smallest amount. But he could not prevent such men from driving. All he could do was call attention to the subject.

### Radiotherapy in Hyperthyroidism

Criticism has been directed against radiotherapy in the treatment of hyperthyroidism, first, because of the resultant pigmentation of the skin, secondly, on account of the production of a large amount of scar tissue around the thyroid and, thirdly, because the treatment requires too long an interval at times from two to three years. In a paper read before the Société médicale des hôpitaux, February 28, Gally and Levy stated that in reply to these objections, one could say that pigmentation did not take place if the technic was correct, that the scar tissue is a sequel of the disease and not of the radiotherapy according to Desplas, and that with the method employed by the authors a much more rapid result can be obtained. They utilize an apparatus capable of delivering 200,000 volts, a thick filter and a large field with a 50 cm distance of the tube from the skin. Large doses are given over as short a time as possible, to avoid too protracted a treatment. As an initial dose 3,000 roentgens is given and this is raised to 4,000 or 6,000 roentgens in severe cases. The total dose is from 10,000 to 12,000 roentgens followed by a rest of from four to six weeks before another series is given. During the past ten years 172 cases have been thus treated at the Necker Hospital after thorough examinations by well qualified internists and including a metabolism test in all cases. Seventy-six of the 172 were mild cases of hyperthyroidism with an increased metabolism of from 20 to 30 per cent; fifty-three were more serious, from 30 to 50 per cent, and twenty-five were very severe, from 50 to 70 per cent. In the first group all were cured or greatly improved, with doses of between 3,000 and 6,000 roentgens. Forty of the fifty-three in the second group were followed up and showed a decrease in the basal metabolism rate of from 20 to 30 per cent. The patients have increased in weight and there has been marked improvement in the symptoms of hyperthyroidism. This group was given from 6,000 to 10,000 roentgens. Three of the fifty-three patients were operated on and irradiated three months after operation. Of the third group (very severe cases) only two patients were obliged to be operated on, but even these two showed marked improvement after irradiation. The only way the success in all these groups can be explained is that the dosage of the irradiation was much higher than is ordinarily employed. No ill effects were noted in any of the cases. In the discussion Haguenau stated that he had examined the majority of the 172 cases both before and after irradiation and could confirm the results obtained by Gally and Levy. There are no contraindications to the treatment even in cases of functional cardiac symptoms. Lian stated that he had observed some good but also some mediocre results. He believed that subtotal thyroidectomy should be preferred to irradiation in the majority of cases, although with the improved technic suggested by Gally and Levy he might change his opinion.

### Pulmonary Atelectasis

In a symposium February 7 and 14 at the Société médicale des hôpitaux the first paper was by Carnot and Lafitte on subacute massive collapse with hemoptysis. A young girl in apparent good health experienced severe pain while exercising

in a gymnasium. An attack of dyspnea was followed by hemoptysis. On admission to the hospital marked cyanosis, dyspnea and retraction of the right half of the thorax were noted. A film showed considerable elevation of the right half of the diaphragm and a displacement of the heart to the right. A diagnosis was made of occlusion of the right main bronchus. The clinical picture was suddenly changed on the fourth day following expectoration of a clot. The symptoms disappeared completely. Although the clinical and radiologic picture is typical in such cases it is seldom recognized, there being only about ten reports of subacute collapse subsequent to a hemoptysis. One must exclude a spontaneous pneumothorax, but here there is expansion and not retraction. In some published case reports the symptoms persisted for as long as six days but ceased immediately after expulsion of a clot. The only treatment is to give expectorants and to combat the hemoptysis. Bronchoscopy is of no avail.

Save of Barcelona, Spain, on the other hand maintained that insufflation of iodized oil, determination of intrapleural pressure, pneumothorax, bronchoscopy and pleuroscopy have enabled him to diagnose the following types of atelectasis: 1. The acute massive form observed after injection of iodized oil, severe hemoptysis and following laparotomy. 2. A chronic irreducible total or lobar form. In cases of bronchiectasis obstruction of a main bronchus or of that of the lower lobe alone have been observed during a period of from ten to fourteen years. In less severe cases this is reduced to from five to seven years. This form of atelectasis is also seen in bronchial occlusion of intrinsic (cancer) or extrinsic (aneurysm) nature. 3. A chronic, slowly developing form. This is observed in primary tuberculous infections of children or adolescents as the result of compression of the bronchi by greatly enlarged lymph nodes. 4. Recurrent or migratory atelectases, seen in temporary occlusion of the bronchi in cases of endobronchial neoplasms. 5. In association with a pneumonia or pleurisy. 6. An incomplete form observed after hemoptyses of tuberculous or traumatic origin with more or less typical signs of parenchymatous involvement but without the presence of a lobar shadow. Elevation of the diaphragm and deviation of the mediastinum and trachea are found and can persist even after the pulmonary symptoms have disappeared. This form is no doubt due to the obstruction of small bronchi associated with a reflex or spastic factor. 7. A reflex form following pleuroscopy in which an adhesion has been touched without being divided. It is also seen in infants during an attack of asthma in the absence of any infection. In the future, more attention will have to be paid to the role of the nervous element in the production of atelectasis.

Kourilsky and Anglade reported experiments on dogs in which the bronchi were obstructed by foreign bodies, by ligation and by action on the nerve supply. Their conclusions are that: 1. The mechanical changes (mediastinophrenic parietal) occur several hours before there is any roentgenographic evidence. In this stage there is absorption of the alveolar air and dilatation of the pulmonary capillaries. 2. The experimental atelectasis is an inert condition of the lung and can undergo repermeabilization in several months or persist without cicatricial sclerosis or infection. 3. Occlusion of secondary bronchi does not yield an air shadow. 4. An atelectasis through irritation of the pulmonary nerves is very difficult to accomplish but it undoubtedly is a clinical entity. They conclude that clinically, atelectasis is a complication of other pulmonary lesions, of a mechanical or an infectious character.

Debré and his associates reported seven cases of pulmonary atelectasis of massive character in children due to compression of a bronchus by a tuberculous lymph node, by a foreign body and after anesthesia. A sudden sensation of suffocation accompanied by extreme dyspnea with intervals of rather dry irrita-

ing cough and the absence of fever should make one think of an acute massive atelectasis (collapse). This diagnosis can be confirmed by a roentgenographic examination. Bronchoscopy with extraction of a foreign body or aspiration of mucus is the best treatment for older children and, with improved technique, can no doubt be applied to infants later.

### Experimental Tuberculosis of Bone

According to Boquet and Laporte of the Pasteur Institute, injection of minute quantities of virulent tubercle bacilli of the bovine type has been followed in rabbits in every instance by osseous and articular lesions which resemble in every respect the histologic picture of tuberculous foci in human beings. The bacilli are carried to the bone by the hematogenous route. There seems to be a relation between such tuberculous localizations and any traumatism. The results of their experiments were reported by Boquet and Laporte at the January 13 meeting of the Academy of Science.

### Notes on the Sterilization of Persons with Hereditary Disease

Hitherto the law to prevent propagation of hereditary disease provided for the sterilization of the tainted persons by surgical intervention only. Henceforth, on the basis of scientific experiments, sterilization by irradiation (roentgen rays or radium) will be permitted in special circumstances. The use of irradiation shall be restricted to cases in which (1) a woman is more than 38 years old, (2) owing to other factors surgical intervention might prove dangerous to the patient (3) on other medical grounds, irradiation of the genitalia is indicated. The woman's consent to the treatment is required, following treatment she must submit to three examinations and in exceptional cases to a second irradiation. The institutions and physicians undertaking this procedure shall be licensed by the minister of the interior.

Mention was made in THE JOURNAL, Sept 28, 1935, page 1051 of a growing opposition to sterilization. A public controversy has lately taken place with regard to this problem. A high ranking Württemberg judge named Goetz, a member of the superior court of hereditary health at Stuttgart, has declared in the *Deutsches Arzteblatt* the official organ of the German medical profession that the law 'places on the doctors a load of unusual responsibility, in that apart from their professional duties they are called on to execute judicial decisions by the performance of operations that serve no therapeutic purpose. This burden seems all the more onerous when the gynecologist performing the intervention has not participated in the previous proceedings and, as in some cases is practically without knowledge of the basis for the sterilization.' Goetz further stated that physicians so involved, while placing duty first experience at the same time a genuine inner reluctance if not disgust. 'At any rate they do not feel much at home in this new role of performer of sterilization operations.' Goetz goes on to speak in the manner of one well informed of the high position enjoyed by medical science and gynecology in Germany. Then he stresses the fact that the law permits but does not make compulsory the issuance of a sterilization order. The Stuttgart hereditary health tribunal has now thanks apparently to a conflict of conscience evolved a rather unorthodox interpretation. To avoid application of the law in certain cases of hereditary disease it is contended that objective prevention or propagation is by no means necessary but only that the likelihood of propagation be removed. Application of the law must be *volksverbunden* (in harmony with popular political concepts) and must not be at variance with the legislative

ideals of the National Socialist *weltanschauung*. Yet these ideals will suffer if, as a result of sterilization, a larger number of unmarried girls indulge in sexual intercourse, a line of conduct still regarded by a large part of the public as disgraceful. Accordingly the Stuttgart tribunal of jurisdiction does not enforce the sterilization law in the cases of certain unmarried girls of tainted heredity "so long as they remain single. Differentiation is thus made between the ability to procreate and the danger of procreation.

Now, as expected, this stand has found opponents in the governmental quarters most concerned, notably in the national public health service commission and specifically in an official of the national health bureau. However, the most vigorous foe of the Stuttgart tribunal's attitude is the national father of medicine, Dr. Wagner, who takes particular exception to the assertion of Judge Goetz that physicians feel their duties under the sterilization laws as a "crushing burden." According to Dr. Wagner the contrary is true, the doctors, he says "cooperate cheerfully in the performance" of these duties.

An article by Dr. Friese, director of the department of racial hygiene of the national public health service commission voices the same disinclination to allow exceptions. This author speaks of those persons with superior endowments who at the same time present symptoms of hereditary disease. He is opposed to exempting such persons from the application of the laws (despite the fact that many judges have made exceptions in particular cases of this sort). The genius of the people as a whole will not suffer if in these rare instances persons with high superior endowments are prevented from propagating. Friese repeatedly emphasizes the idea that no one shall be otherwise discriminated against on account of sterilization. He further considers it erroneous to speak of a person with hereditary disease being 'saved' from sterilization. Such an expression, he says, is no more reasonable than if one were to speak of a man being 'saved' from military service or a woman 'saved' from motherhood.

Divergent opinion with regard to this problem has been reflected by other happenings. The controversy that took place at the International Hospital Congress at Rome last May is an example. A report of this affair appeared in an official German source, *Der öffentliche Gesundheitsdienst*, organ of the national public health service commission and other governmental bodies. According to this report (which is based on Italian advices) the German delegation requested that, in addition to the principal topic of the gathering the congress should take up the question of sterilization. The Netherland physicians opposed the motion and it was tentatively decided to postpone any such discussion until the next congress, in Paris in 1937. Next the pope in the course of receiving the delegation declared that were other countries to adopt the official German attitude toward sterilization it would signify a reversion to paganism. At the final session of the congress the Netherland delegates introduced a resolution censuring Professor Schultze of Munich an official of the health administration, whose demands were offensive to the religious and ethical sensitivities of a section of the delegates. The Spanish, the Irish and in particular the French delegations also ranged themselves against the German proposal. The French delegates said that their government would refuse to sponsor the gathering if the subject of eugenics and sterilization was to be discussed. It was then voted that the topic would not be taken up by the next congress.

Most interesting is the recently developed Swiss attitude toward sterilization. In an article in the *Schweizerische medizinische Wochenschrift*, the Basel gynecologist Professor Labhardt emphatically characterizes as unsatisfactory and dangerous all contraceptive devices such as occlusive pessaries, cup pessaries and in particular, intra uterine instruments, an attitude similar to that of the German partisans (THE JOURNAL, Aug 24 1935).

p 611) He assumes a connection between the constant manipulations of the vagina and uterus and the amazing increase in the number of tubal pregnancies in recent years. The University of Basel clinic records 1078 sterilizations for all indications during the years from 1920 to 1934. In five of seven fatal cases recorded, death was caused by embolism and the patients were women who had undergone an operation for correction of the position of the uterus and on whom sterilization had been performed as a secondary measure. In such cases the fatal outcome cannot be attributed to the sterilizing treatment. With regard to the efficacy of the operation (subperitoneal tubal resection according to Labhardt's own method) no subsequent intra-uterine pregnancy occurred in any of the cases although three instances of subsequent tubal pregnancy were noted. To determine somatic and psychic results 652 of the women patients were submitted to a questionnaire. Of this number, 612 women expressed themselves as pleased with the operation. Forty women refused to commit themselves and five of these manifested a feeling of inferiority.

With regard to sterilization of men (by ligation of the spermatic cord) no postoperative psychic or physical changes were observed in 300 cases reported by the Basel urologist Professor Suter.

Some further ideas of Professor Labhardt coincide with a resolution passed by the Basel Medical Society, a body which at the instance of the public prosecutor's office has examined the question. According to the society's pronouncement sterilization is considered a legitimate measure (1) when indicated by medical conditions or (2) when indicated as a eugenic measure to prevent transmission of hereditary disease (this is the fundamental concept of the German legislation but the Basel group refrains from entering into details) and finally be it considered that (a) the examination of whether or not this or that individual person or married couple should have offspring is abandoned (b) the prevailing economic situation forces many married couples to practice an intelligent birth control (c) chemical, mechanical and other contraceptive measures are unreliable are in some instances dangerous and in no case insure against pregnancy, (d) birth control by interruption of pregnancy (abortion) when practiced repeatedly is absolutely inadmissible, (e) as a result of the legal restriction of contraceptive measures however, women frequently resort to abortions. It is therefore the duty of the physician to aid in checking the abortion evil and to suggest a better way out of the difficulty. Operative sterilization provides an adequate solution for many married couples. In the absence of both medical and eugenic indications, sterilization should be carried out on a couple who are already the parents of healthy children and who submit a written request with full explanation of the circumstances.

Labhardt's acceptance of official German medical opinion is far from complete. The Swiss and German attitudes are frequently divergent, even antagonistic.

A word should be said about marriages contracted by sufferers from hereditary disease. According to an official of the ministry of justice there is nothing to prohibit a sterilized man from marrying a sterilized or naturally barren woman. But marriage between a person of sound heredity and one of tainted heredity is a different matter. A fundamental legal decision approved by the ministry of justice applies in such cases whereby a person of healthy heredity is prohibited from marrying a person of tainted heredity even when the latter has been rendered sterile. According to the National Socialist Anschauung, the *raison d'être* of marriage is essentially if not entirely the breeding of healthy offspring for the maintenance of the nation. This concept forms the underlying justification for the prohibition of marriage between a person of healthy heredity who possesses the ability to procreate and a person who is sterile.

### Sodium Arsenite in Treatment of Leishmaniasis Americana

Prof Aguar Pupo of the Faculty of Medicine of São Paulo has published a preliminary report on his results in a large number of cases from intramuscular injections of sodium arsenite in the treatment of leishmaniasis americana of the skin. Sodium arsenite, when administered through the muscular route diffuses into the circulation quickly and does not accumulate in the liver. When it is given by mouth, a large portion of the drug goes to the liver through the portal vein and becomes fixed there (hepatic arsenicopexis). A dose half as large as that used for oral administration was given by the author in the first cases of cutaneous leishmaniasis americana treated by the intradermal route. The dose resulted in cure of the cutaneous lesions. Because of the resistance of the lesions of the mucosa however, and the tolerance of the patients to the drug it was found that a dose of either 0.005 Gm three times a week or 0.01 Gm twice a week offers the best results. In these cases calcium chloride should be given simultaneously by mouth because, owing to its desensitizing and diuretic properties, it protects the kidneys and increases the tolerance to the drug. Sodium arsenite is an official drug accepted by international pharmacopeias and the preparation of the solution for intramuscular injections is easy. It has advantages also over the antimony and potassium tartrate because the latter should be given intravenously. Acute arsenicalism in its several forms, such as nitritoid crises, desquamative erythrodermia and acute yellow atrophy of the liver, which may complicate the use of arsenical compounds when given in large doses does not complicate the sodium arsenite treatment because of the small doses employed.

### Botelho's Diagnostic Seroreaction in Cancer of Uterus

Dr Castro Stebe Jr of the Faculty of Medicine of Rio de Janeiro has published "Técnica e resultados da Soro-Reacção de Botelho e sua aplicação em Gynecologia," a book in which he reports positive results in twenty-one cases of cancer of the uterus. The tumors were atypical epithelioma in one case, carcinoma in ten cases, epithelioma in two cases, spinocellular epithelioma in six cases, mixed carcinoma in one case and benign tumor in one case. The author fully reviews the subject and concludes that Botelho's seroreaction permits the making of a diagnosis in 90 per cent of the cases. It is also important because it permits the administration of early treatment. The serologic diagnosis should be verified however by careful clinical examination of the patients. The author's results show that there is a perfect accord between the histopathologic diagnosis and the results of the reaction.

### Brazilian Medical Congresses

The first Congress of Urology recently held at Rio de Janeiro, was attended by delegates from France, Germany, the United States, Belgium, Italy, Argentina, Chile, Uruguay and other countries.

The first Brazilian Congress for the Study of Cancer was recently held in Rio de Janeiro under the auspices of the Sociedade de Medicina e Cirurgia of Rio de Janeiro.

The first Congress of Regional Medicine was held last December in Bahia.

The first Medical Congress of Ceara was held in January in Ceara with the attendance of the majority of the physicians of the northern states of Brazil.

## Marriages

GLEN D. LARRISON, Morocco, Ind. to Mrs. May Mosier Martin of Kankakee, Ill., in Aurora, Ill., January 3

JAMES ROBY GUDGER, Scarsdale, N. Y., to Miss Irene Cornelia Dobias at Prague, Czechoslovakia, February 3

SAMUEL V. GRANATA to Miss Ruth Steegall, both of Beaumont, Texas, January 12, at Lake Charles, La.

THOMAS GREGORY DOUGHERTY to Miss Kathleen Cecelia Brock, both of New York, February 22

MILLARD S. ROSENBLATT, Portland, Ore., to Miss Carolyn Guthman of Seattle, February 22

EDWARD C. HOLSCHER, St. Louis, to Miss Dorothy Hagar of Cambridge, Mass., recently

ROBERT E. GARY to Miss Eunice Annette Greene both of Waycross, Ga., February 25

WILLIAM P. STEPHENS, Portsmouth, Va., to Miss Hilda Spear of Atlanta, Ga., February 22

WILLIAM A. K. SEALE to Miss Ilene Fleniken, both of Sulphur, La., February 9

WILLIAM A. GARDNER, Atlanta, Ga., to Miss Rorie D. Stewart at Decatur, February 22

## Deaths

Arthur Baldwin Duel, New York, Harvard University Medical School, Boston 1894, member of the American Laryngological, Rhinological and Otological Society, member and past president of the American Otological Society, and chairman of the board of trustees of the Research Fund, trustee and formerly vice president of the New York Academy of Medicine, fellow of the American College of Surgeons, honorary fellow of the Societe de laryngologie des hopitaux de Paris, professor of otology at the New York Polyclinic Medical School and Hospital, 1908-1913, surgeon-director of the ear department, Manhattan Eye, Ear and Throat Hospital, consulting aural surgeon to the Babies, Stuyvesant Square, New York Health Board and New York Post-Graduate hospitals, Flushing (N. Y.) Hospital and the Englewood (N. J.) Hospital, was chairman of a committee that organized examination of airmen during the World War, was the author of the chapter on otology in various systems of medicine and with others wrote "Nursing in Diseases of the Eye, Ear, Nose and Throat", for many years a member of a subcommittee of the Noise Abatement Commission, aged 65, died, April 11, at his country home at Laurelwood.

Proceso Gabriel, Manila, P. I., University of Santo Tomas College of Medicine and Surgery, Manila 1903, member of the Philippine Islands Medical Association, formerly vice dean, professor of hygiene, sanitation, preventive medicine and epidemiology at his alma mater, at one time lecturer on infant mortality, University of the Philippines College of Medicine, for many years a member of the Council of Hygiene of the Bureau of Health, aged 58, died recently, of heart disease.

William Mason Cott, Okmulgee, Okla., St. Louis College of Physicians and Surgeons, 1896, member of the Oklahoma State Medical Association, past president of the Okmulgee County Medical Society, for fifteen years member of the board of education, aged 66, on the staff of the Okmulgee City Hospital, where he died February 7, of thrombosis of the left arm and right leg and infection of the lung due to fracture of the ribs in an accidental fall.

Alice Mary Seabrook, Beverly Hills, Calif. Woman's Medical College of Pennsylvania, Philadelphia, 1895, member of the Medical Society of the State of Pennsylvania, at one time vice president of the National Hospital Association, for ten years a member of the State Board of Registration for Graduate Nurses in Pennsylvania, for eighteen years medical superintendent of the Woman's Hospital, Philadelphia, aged 79, died March 10.

John M. Brister, Medical Director, Rear Admiral, U. S. Navy, Washington, D. C., Medico-Chirurgical College of Philadelphia, 1898, entered the navy in 1900, inspector of the medical department activities, bureau of medicine and surgery of the Navy Department, fellow of the American College of Surgeons, aged 58, died April 10 in the U. S. Naval Hospital of coronary thrombosis.

William Henry Oates, Mobile, Ala., Bellevue Hospital Medical College, New York, 1898, past president of the Mobile County Medical Society, chairman of the county board of health, veteran of the Spanish-American and World wars, one time state prison inspector, trustee of the Alabama Polytechnic Institute, Auburn, aged 64, died, March 1, of pneumonia.

Joseph Samuel Cohen, Easton, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1907, health officer of Easton, formerly assistant demonstrator of physical diagnosis, Medico-Chirurgical College of Philadelphia, aged 51, on the staff of the Easton Hospital, where he died, March 7, of carcinoma of the hepatic ducts and bronchopneumonia.

Abdu M. Ibrahim, Northampton, Mass., Tulane University of Louisiana School of Medicine, New Orleans, 1922, member of the Medical Society of the State of New York and the American Psychiatric Association, aged 47, on the staff of the Veterans Administration Facility, where he died, January 15, of coronary sclerosis and thrombosis.

Thomas Allen Clark, Mount Vernon, Ill., St. Louis University School of Medicine, 1904, member of the Illinois State Medical Society, past president and secretary of the Jefferson-Hamilton County Medical Society, aged 61, died, January 2, in the Missouri Baptist Hospital, St. Louis, of acute dilatation of the heart and ulcer of the duodenum.

Howard Lester Farquhar, Pittsburgh, University of Pennsylvania School of Medicine, Philadelphia, 1916, member of the Medical Society of the State of Pennsylvania, fellow of the American College of Surgeons, on the staff of the South Side Hospital, aged 46, died, January 30, of cerebral hemorrhage and essential hypertension.

Philip Joseph Sheridan, Oil City, Pa., New York Homeopathic Medical College and Flower Hospital, 1908, member of the Medical Society of the State of Pennsylvania, served during the World War, aged 51, medical director of the Grandview Sanatorium, where he died, March 12, of tuberculosis of the lungs.

Thomas Ethelbert McConnell, New Kensington, Pa., Western Pennsylvania Medical College, Pittsburgh, 1891, member of the Medical Society of the State of Pennsylvania and the American Academy of Ophthalmology and Otolaryngology, aged 66, died in January of coronary occlusion and arteriosclerosis.

Louis M. Weinfield, San Antonio, Texas, Southwestern University Medical College, Dallas, 1905, member of the State Medical Association of Texas, formerly member of the state board of health, served during the World War, aged 63, died March 13, of lymphosarcoma of the mediastinum with metastases.

Helena Knauf Wink, Jamestown, N. D., University of Michigan Department of Medicine and Surgery, Ann Arbor 1883, member of the North Dakota State Medical Association, aged 81, died, February 16, in a local hospital, of burns received when gasoline with which she was cleaning clothes exploded.

Louis Bazet, San Francisco, Jefferson Medical College of Philadelphia, 1876, formerly member of the city and state boards of health, aged 87, at one time on the staffs of the San Francisco Polyclinic and the French Hospital, where he died February 21, of arteriosclerosis and chronic myocarditis.

Henry Joseph Eugene Newnam, Waymart, Pa., Jefferson Medical College of Philadelphia, 1905, formerly assistant demonstrator of obstetrics at his alma mater, on the staff of the Fairview State Hospital, aged 53, died, March 14, in St. Joseph's Hospital, Carbondale, of pneumonia.

Vaughn Rhea Eleazer, Cho, S. C., Medical College of the State of South Carolina, Charleston, 1933, member of the South Carolina Medical Association, aged 34, died, January 30, in the Newberry County Hospital, Newberry, of complications following an operation for appendicitis.

George S. Marbarger, New Ringgold, Pa., Jefferson Medical College of Philadelphia, 1894, member of the Medical Society of the State of Pennsylvania, for many years member of the school board, secretary of the town council, aged 74, died March 7, of cerebral hemorrhage.

Royal Shepherd Loving, Major, M. C., U. S. Army, Fort Lewis, Wash., served during the World War, was appointed a captain in the medical corps of the U. S. Army in 1920 and in 1929 was promoted to major, aged 58, died January 22, of coronary thrombosis.

Daniel Wadsworth Frye, Pittsburgh, Western Pennsylvania Medical College, 1897, member of the Medical Society of the State of Pennsylvania, served during the World War, aged 65, died February 9, in the Mercy Hospital, of osteitis fibrosa cystica and cerebral hemorrhage.

**Christian Frederick Jappe**, Davenport, Iowa State University of Iowa College of Medicine, Iowa City, 1895, member of the Iowa State Medical Society, formerly on the staffs of St Luke's and Mercy Hospitals, aged 76, died, February 3, of endocarditis and myocarditis

**Earl Donahue Brewer**, New York, Washington University School of Medicine, St Louis, 1927, assistant neurologic surgeon to the Neurological Institute and assistant consulting neurologic surgeon to the Vanderbilt Clinic, aged 30, died, January 25, of heart disease

**Frank A Osincup** ☉ Waverly, Iowa, College of Physicians and Surgeons of Chicago, 1893, past president of the Bremer County Medical Society, for many years mayor of Waverly on the staff of St Joseph Mercy Hospital, aged 73, died, January 31, of heart disease

**William Fred Seidler** ☉ Belleville N J, Bellevue Hospital Medical College, New York, 1891 also a pharmacist formerly on the staffs of St James Hospital and St Michael's Hospital, Newark, aged 75, died, February 22, as the result of a fall in his home

**John William Bowman**, Lemoyne, Pa Jefferson Medical College of Philadelphia, 1877, member of the Medical Society of the State of Pennsylvania, formerly school director and member of the state legislature, aged 89, died, February 15, of bronchopneumonia

**Arthur John Taylor**, Hop Bottom, Pa, Jefferson Medical College of Philadelphia 1890, member of the Medical Society of the State of Pennsylvania, bank president, formerly county coroner, aged 71, died, February 17, of senile dementia and arteriosclerosis

**Donald Badenoch McGee**, Leavenworth, Kan University of Michigan Medical School, Ann Arbor, 1933, member of the Michigan State Medical Society, intern at the U S Penitentiary Hospital, aged 30, died, February 13, of poison self administered

**Earl William O'Donnell** ☉ Los Angeles, College of Physicians and Surgeons, Los Angeles, 1915, served during the World War, on the staff of the Queen of Angels Hospital aged 44, was killed, February 16, when his automobile skidded and overturned

**Walter D Martin**, Los Angeles State College of Physicians and Surgeons, Indianapolis, 1907, served during the World War, formerly connected with the U S Veterans Bureau, aged 53, died, February 26, of acute coronary thrombosis

**John Leaming McBride** ☉ Pittsburgh University of Pennsylvania Department of Medicine Philadelphia, 1906 member of the Associated Anesthetists of the United States and Canada aged 57, died, February 5, of a self inflicted bullet wound

**Mary Anna Israel Nettle**, Parker, Ariz, Howard University College of Medicine, Washington, D C, 1905, formerly physician in the Indian Service aged 54, was found dead, March 3, of an overdose of morphine, self-administered

**Abraham T Welker**, Collomsville, Pa, University of Pennsylvania Department of Medicine Philadelphia 1886 member of the Medical Society of the State of Pennsylvania, aged 78, died, February 7, of hemiplegia and arteriosclerosis

**Jacob Lindsey Short**, Houston, Texas, University of Texas School of Medicine, Galveston 1896 member of the State Medical Association of Texas, aged 62 died February 4, of coronary thrombosis and hypertensive heart disease

**R N Herbert Harsh**, Nashville, Tenn, University of Nashville Medical Department 1892 served with the American Red Cross during the World War aged 63 died, January 26, in a local hospital of carcinoma of the lung

**William Skidmore Ellis**, Jonesboro Ark, Berumont Hospital Medical College, St Louis, 1893 also a minister aged 76 died February 21, in St Bernard's Hospital of injuries received when he fell out of a moving automobile

**Frederick William Gilbert**, Ridgewood N J Bellevue Hospital Medical College, New York 1897, on the staff of St Joseph's Hospital, Paterson aged 62 died, February 12 of myocarditis, endocarditis and chronic nephritis

**Russell Calvin Kelsey**, Portland Ore Physio Medical College of Indiana Indianapolis 1888, College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois 1890, aged 78 died, January 31

**Homer Augustus Wall**, Ochlocknee Ga University of Georgia Medical Department, Augusta 1892 member of the Medical Association of Georgia aged 67 died January 27, of angina pectoris hypertension and nephritis

**Arthur Sumner Hayden**, Des Moines Iowa, State University of Iowa College of Homeopathic Medicine, Iowa City, 1896, member of the Iowa State Medical Society, aged 73, died, January 25 of hypostatic pneumonia

**Michael E Kapinya** ☉ Pittsburgh Magyar Kiralyi Pázmány Petrus Tudományegyetem Orvosi Fakultása Budapest, Hungary, 1920 aged 42 died January 27, of carbon monoxide poisoning due to fumes from a gas stove

**Fowler Lyons**, Turbotville Pa Jefferson Medical College of Philadelphia, 1891 also a druggist member of the Medical Society of the State of Pennsylvania, aged 75, died, February 8, of angina pectoris and arteriosclerosis

**James Coad Riordan** ☉ Pocahontas, Iowa Rush Medical College, Chicago, 1894, past president and secretary of the Pocahontas County Medical Society, aged 67, was found dead in bed, February 7, of myocarditis

**George William Packer**, Fall River, Mass College of Physicians and Surgeons, Boston, 1903 member of the Massachusetts Medical Society, city physician aged 56, died, March 4, of coronary occlusion

**Henry P Gerlach**, West Palm Beach, Fla Medical College of Ohio Cincinnati 1880, aged 77, died January 31, in the Good Samaritan Hospital, of a cerebral hemorrhage, due to injuries received in a fall

**Smith A Hoge**, Rices Landing Pa College of Medicine and Surgery, Chicago, 1901, member of the Medical Society of the State of Pennsylvania, aged 66, died suddenly, January 28 of coronary occlusion

**Dennis E Fisher**, Ncedmore Pa Baltimore Medical College 1883 member of the Medical Society of the State of Pennsylvania, aged 82, died, February 26, of arteriosclerosis and chronic myocarditis

**James King Hatchett**, Scotland Ark (licensed in Arkansas in 1903), aged 67, died, February 7, in the Baptist State Hospital, Little Rock, of myocardial insufficiency, shock and adenocarcinoma of the cecum

**Henry Miller Sultzbach**, Lancaster, Pa Medico-Chirurgical College of Philadelphia, 1894, member of the Medical Society of the State of Pennsylvania, aged 67, died, February 4, of lobar pneumonia

**David H Hain**, Sinking Spring Pa Jefferson Medical College of Philadelphia, 1881, aged 76, died, February 21, in the Reading (Pa) Hospital, of septicemia, as the result of an abrasion on his hand

**George Stewart Murphy**, Los Angeles, John A Creighton Medical College Omaha 1896, aged 67, died, February 7, in the National Military Home, Sawtelle, of bronchopneumonia and diabetes mellitus

**George Bourne Ferguson**, New York Bellevue Hospital Medical College New York, 1894, member of the Medical Society of the State of New York, aged 68 died recently, of cerebral hemorrhage

**August Henry Bethke**, Marshalltown, Iowa Bennett College of Eclectic Medicine and Surgery, Chicago, 1905, aged 69, was asphyxiated February 2, as the result of fumes escaping from a gas heater

**Albert Hamilton Story**, Augusta, Ga, University of Georgia Medical Department Augusta 1880 aged 76 died January 29, of cerebral hemorrhage, valvular heart disease and arteriosclerosis

**William Cline Allen** ☉ Blairstown N J, University of the South Medical Department Sewanee, Tenn 1895 Jefferson Medical College Philadelphia, 1896, aged 64, died, February 7 of pneumonia

**Raymond E Heacock**, Bethlehem Pa Eclectic Medical College, Cincinnati 1911 member of the Medical Society of the State of Pennsylvania, aged 46, died, March 6 of cardiovascular disease

**Louisa Eastham Blattner**, St Louis, American Medical College St Louis 1894 aged 74 died February 10 in the City Hospital of a skull fracture received when struck by an automobile

**Augustus Moen Hurlbutt**, Glenbrook Conn College of Physicians and Surgeons Medical Department of Columbia College New York, 1879, aged 81, died March 2, of coronary occlusion

**William Henry Green** ☉ Bridgewater Iowa Drake University Medical Department Des Moines 1903 aged 61 died February 10, in the Methodist Hospital, Des Moines, of osteomyelitis

**George Franklin Brown** ♂ Sherman, Texas, Bellevue Hospital Medical College, New York, 1897, on the staff of St Vincent's Sanitarium, aged 65, died, February 4, of heart disease

**Hugh T Crouch**, Bardwell, Ky, Missouri Medical College St Louis, 1882, past president and secretary of the Carlisle County Medical Society, aged 80, died, February 19, of pneumonia

**John Thomas O'Brian**, Ridgefield Park, N J, University of Vermont College of Medicine, Burlington 1925, aged 33, died, February 16, in St Mary's Hospital, Passaic, of pneumonia

**Albert L Boen**, Knoxville Ark, University of Arkansas School of Medicine, Little Rock, 1907, member of the Arkansas Medical Society, aged 67, died, February 5, of cerebral hemorrhage

**Allan McNally**, Louisville Ky, Louisville Medical College, 1894, member of the Kentucky State Medical Association, aged 63, died, February 11, of acute dilatation of the heart

**John R Boatwright**, Linton Ky, St Louis College of Physicians and Surgeons, 1915, member of the Kentucky State Medical Association, aged 55, died, February 6, of pneumonia

**John Jesse Carroll Rembert** ♂ Okmulgee Okla, University of Tennessee College of Medicine, Memphis, 1914, county health officer, aged 53, died February 12 of septicaemia

**Robert M Campbell**, Denver Denver College of Medicine 1893, police surgeon, aged 68, died February 11, in the Denver General Hospital, of injuries received in an automobile accident

**Raymond John Striegel**, Long Beach Calif, University of Buffalo School of Medicine, 1921, member of the California Medical Association, aged 39, died, February 26, of pneumonia

**Bayard Sullivan**, Palo Alto Calif, Vanderbilt University School of Medicine Nashville Tenn 1909, served during the World War, aged 50, died, February 9, of cerebral hemorrhage

**John Thomas Vansant**, Paris, Ky, New York Homeopathic Medical College, 1879, member of the Kentucky State Medical Association, aged 82, died, February 14, of coronary thrombosis

**Thomas Wilson Powers**, Birmingham, Ala, Louisville (Ky) Medical College, 1903, aged 60, died March 10, in the Norwood Hospital, of septicaemia following an injury of the foot

**Benjamin C Williams**, Cambridge, Mass, Maryland Medical College, Baltimore, 1902, Middlesex College of Medicine and Surgery, Cambridge, 1923, aged 71, died January 1

**Josiah Adams Simpson**, San Francisco, Cooper Medical College, San Francisco, 1891, aged 73, died in February in St Joseph's Hospital, of myocarditis and arteriosclerosis

**George B Wade**, Jacksboro, Texas, University of Tennessee Medical Department, Nashville 1890, aged 71, died, recently, in a hospital at Fort Worth of heart disease

**Llewellyn Phelps Barbour**, Rialto, Calif, Western Reserve University Medical Department, Cleveland, 1882, aged 76, died, March 8, of lobar pneumonia and arteriosclerosis

**Louis J Guier**, Cartago, Costa Rica, Central America, Jefferson Medical College, Philadelphia, 1909, aged 54, died, March 31, of cerebral hemorrhage and heart disease

**James Daniel Baucum** ♂ Longview, Texas, University of Louisville (Ky) Medical Department 1910, county health officer, aged 46, died, February 7, of heart disease

**Stephen F O'Brien**, Hillsboro Ky, Eclectic Medical Institute, Cincinnati, 1892, aged 67, died March 15, in the Hayswood Hospital, Nashville, of cardiorenal disease

**John C Hunter**, Apollo, Pa, College of Physicians and Surgeons Baltimore 1893, aged 70, was found dead February 26, of a bullet wound, probably self-inflicted

**Felice Bongiorno** ♂ Waltham, Mass, Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy 1919, aged 42, died February 20, of coronary thrombosis

**Joseph Schwartz Musgrove**, Idalou, Texas, University of Nashville Medical Department, 1908, aged 58, died March 4, of coronary occlusion and hypertension

**Charles Purnell Smith**, Martinsville, Va (licensed in Virginia by the Exemption Law of 1885), aged 74, died January 17, of carcinoma of the prostate

**Walter Herschel Kidder**, Oswego, N Y, University of Buffalo School of Medicine 1893, aged 68, died February 25, of myocarditis and bronchopneumonia

**George D Pendell** ♂ Derby, Kan, Beaumont Hospital Medical College St Louis 1891, aged 72, died February 18, in a hospital at Wichita, of influenza

**Samuel Hartley Hagler**, Austin, Texas, Tulane University of Louisiana Medical Department, New Orleans (Ky) aged 59, died suddenly in February

**George Troy Bailey** ♂ Chicago, Northwestern University Medical School, Chicago, 1894, aged 71, died recently, of coronary sclerosis and arteriosclerosis

**John Peter Strunk**, Andale, Kan, St Louis University School of Medicine 1933, aged 29, died, February 3, in a hospital at Wichita, of septicaemia

**Charles Wyche**, Charlotte Hall, Md, College of Physicians and Surgeons, Baltimore, 1893, aged 64, died, January 27, of a gunshot wound, self inflicted

**Charles Henry Paige**, Fort Dodge, Iowa, University of the City of New York Medical Department, 1880, aged 48, died, February 19, of nephritis

**George Davidson Tallman**, Van Wert, Iowa, Marion University of Medicine, St Louis, 1898, aged 73, died, February 1, of tricuspid insufficiency

**William Patrick Donovan** ♂ St Louis, St Louis University School of Medicine, 1923, aged 39, was killed March 15, in an airplane accident

**Lemuel Lafayette Jones**, Greenville, Texas, University of Louisville (Ky) Medical Department, 1887, aged 80, died February 14, of pneumonia

**Edwin Eareckson**, Philadelphia, Jefferson Medical College of Philadelphia 1882, aged 78, died, February 27, of chronic myocarditis and nephritis

**Robert Arthur Jones**, Birmingham, Ala, University of Louisville (Ky) Medical Department, 1886, aged 70, died March 11, of pneumonia

**David Broderick Hanna**, Stoneboro, Pa, Jefferson Medical College of Philadelphia, 1884, aged 75, died, February 6, of cerebral hemorrhage

**Joseph L Abeln**, Dubuque, Iowa, St Louis College of Physicians and Surgeons, 1900, aged 57, died, February 21, of coronary thrombosis

**Edward Gordon Baker**, Wangan, Mo, Barnes Medical College, St Louis, 1897, aged 64, died, February 11, of coronary sclerosis

**George Stewart Kirby**, Mauch Chunk, Pa, Hahnemann Medical College of Philadelphia, 1882, aged 75, died, March 3, of heart disease

**Eli Browning**, Mediapolis, Iowa, State University of Iowa College of Medicine, Iowa City, 1894, aged 78, died, February 10, of pneumonia

**Adolphe Paul Delcourt**, Hammond La, University of Louisiana Medical Department, New Orleans, 1901, aged 56, died, January 26

**John C Norcott**, Little Rock, Ark, Memphis (Tenn) Hospital Medical College, 1891, aged 77, died, February 25, of lobar pneumonia

**Edward A Crueger** ♂ Philadelphia, Medico Chirurgical College of Philadelphia, 1894, aged 74, died, March 12, of heart disease

**Najeeb Mitry Saleeby** ♂ Baguio P I, Bellevue Hospital Medical College, New York, 1897, aged 64, died recently, of heart disease

**Stephen Edward Maddox**, Fayette Ala, Chattanooga Medical College, 1901, aged 64, died, February 13, of cerebral hemorrhage

**Hugh Thomas Blackledge**, Commerce Mo, St Louis Medical College, 1888, aged 72, died, February 18, of chronic myocarditis

**Adolph J Neas**, Parrottsville, Tenn, Medical Department of Grant University, Chattanooga, 1900, aged 65, died, January 30

**Clara Emerette Gary**, Boston, Boston University School of Medicine, 1885, aged 75, died, February 15, of hemiplegia

**Elkanah Payne** ♂ Lakeview, Texas (licensed in Texas under the Act of 1907), aged 64, died, January 14, of pneumonia

**J Frank Houston**, Alexandria, Ky, Medical College of Ohio, Cincinnati, 1888, aged 77, died, February 21

**W W Heard**, Marshall, Ark (licensed in Arkansas in 1903), aged 82, died, January 24, of heart disease

**Frank Hanna**, Walnut Iowa (licensed in Iowa in 1889), aged 87, died, February 10, of chronic prostatitis

**L K Robertson**, Parks, Ark (licensed in Arkansas in 1903), aged 90, died, March 8, of senility

## Bureau of Investigation

### DILEX-REDUSOLS

#### A Dinitrophenol Nostrum Declared Fraudulent and Debarred from the United States Mails

Now YOU too can take off pounds of ugly fat the safe easy quick way! NO DIETING NO SELF DENIAL NO STRENUOUS EXERCISES! Sounds too good to be true?

These are the words of a typical alluring advertisement for "Redusols." And it was too good to be true. For the Postmaster General declared that the Dilex Institute, the Dilex Institute Inc., the Dilex Method, Madeline M. McCarthy, and their officers and agents were engaged in conducting a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises.

Women with beautiful figures, as shown in the accompanying illustration were prominently featured in the Dilex advertising. Indeed, the copy was so arranged that the reader might easily assume that the glorified damsel represented had herself reduced by the use of the Dilex Compound.

"Reduced 37 pounds with Dilex Redusols" writes Mrs. H. H. Langley. Beneath this statement as will be seen appeared the picture of a svelte example of femininity clad in a somewhat abbreviated undergarment. Closely thereto is the further statement "Note Mrs. Langley used the safe Dilex-Redusol method over a period of 10 weeks." By this clever arrangement of advertising copy the exploiter gave the impression that the alluring figure was that of Mrs. Langley in person when, as a matter of fact, the picture was not that of Mrs. Langley, but one posed by a professional model.

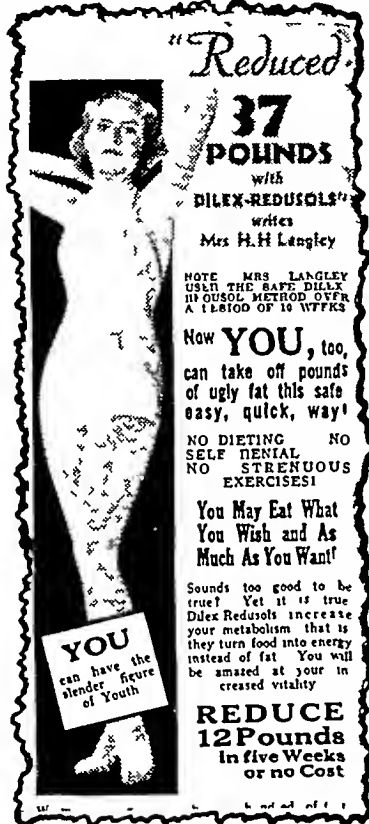

The advertisement also reproduced what were termed reports of amazing reductions of from 35 to 50 pounds and without harm. The Bureau of Investigation might also have added the pitiful story of a Vermont woman who lost 30 pounds but who received in exchange a persistent numbness of both legs granular opacities in the lenses of both eyes—cataracts—and a blurring of both optic discs from the safe easy and quick Dilex-Redusols.

Prospective victims—and the reports indicate that some 75 to 100 persons ordered this nostrum daily at \$3 per order in response to the 'come-on' advertisements—received a letter signed by Mrs. Madeline M. McCarthy reading in part:

I have your inquiry and am enclosing you herewith a leaflet descriptive of REDUSOLS. With these capsules you can take off weight safely and easily as our physicians advocate.

REDUSOLS are absolutely harmless when taken in accordance with the directions. They do not contain thyroid and will have no negative reactions.

Patent medicine advertising is generally at some pains to state what the product does not contain but seldom if ever, what it does contain. Mrs. McCarthy calls attention to the

**"Reduced"**  
**37 POUNDS**  
with  
**DILEX-REDUSOLS**  
writes  
**Mrs. H. H. Langley**

NOTE: MRS. LANGLEY USED THE SAFE DILEX REDUSOL METHOD OVER A PERIOD OF 10 WEEKS.

Now **YOU**, too, can take off pounds of ugly fat this safe easy, quick, way!

NO DIETING NO SELF DENIAL NO STRENUOUS EXERCISES!

**You May Eat What You Wish and As Much As You Want!**

Sounds too good to be true? Yet it is true! Dilex Redusols increase your metabolism that is they turn food into energy instead of fat! You will be amazed at your increased vitality!

**REDUCE 12 Pounds in five Weeks or no Cost**

**YOU** can have the slender figure of Youth

absence of thyroid, but, of course, does not mention dinitrophenol. All will agree most heartily that Dilex may have "no negative reactions", reports in medical literature on dinitrophenol contain numerous accounts of most positive harmful reactions.

Following the modern advertising trend of misleading general statements such as "Doctors endorse," "Physicians say," "Hospitals and nurses recommend," sales manager McCarthy did not hesitate to refer to "our physicians" in the first paragraph of the "come-on" letter, it was implied that the Dilex concern employed a staff of medical advisers. Actually, the Dilex Institute did not employ any physicians, but occasionally an available physician was consulted. The occasionally-consulted physician on questioning by the post office authorities, "thought" that the Dilex capsules contained less than one grain of dinitrophenol. Even this information, however, was not correct, according to the report of the government analyst. The treatment actually consisted of ninety two grain capsules containing a mixture consisting of one and one-half grains of dinitrophenol and one-half grain of milk sugar. With true "patent medicine" callousness, the exploiter nevertheless advertised.

Read your daily newspapers and magazines—heed their warning against the use of drugs taken unknowingly as far as the results and reactions are concerned. You are safe with DILEX REDUSOLS can be taken without any possibility of injury to the system.

The repeated statement in the Redusols advertising that the nostrum was "absolutely harmless" is, of course, an obvious falsehood. The representation contained in the advertisements that Dilex-Redusols are effective because they "remove the cause of obesity," was without foundation and just another lure to the obese. There is no scientific justification for representing that anything containing the powerful and dangerous dinitrophenol ever removed the cause of obesity, unless it permanently removed the patient.

During the hearing, Mrs. McCarthy, who was sales manager for the Dilex outfit, claimed she had reduced her own weight 30 or 40 pounds with Redusols, and without harmful effects. Perhaps she had decreased her weight at one time to 138 pounds, but the post office officials noted that it had thereafter perceptibly increased. At the time of giving testimony she was obviously obese and overweight and refused to get on the scales to permit ascertaining her present weight. Moreover, laboratory reports of examination of Mrs. McCarthy's blood, which she produced, revealed significant decreases in the number of white blood cells, which at one time amounted to 50 per cent. This, however, she blamed on "marital inharmonies" [sic] rather than Redusols.

A New York physician—one Robert G. Carlin—who was "occasionally consulted" by the Dilex people displayed a lamentable lack of knowledge concerning various important matters connected with obesity, dieting, and the determination of the deleterious effects of dinitrophenol. He admitted that he could not define or describe such an elementary dietetic term as the calory, that he could not name the secretions of the pancreas and that he could not state which group of white blood corpuscles should be studied in a blood examination to detect agranulocytosis or granulocytopenia. And yet he was set forth as a consultant!

#### SUMMARY

The postal authorities found the officers of the Dilex Institute owner of the Redusols business—President William H. Door, Vice-President Maybelle Ryerson, and Secretary-Treasurer Dorothy T. Simms—to be the perpetrators of a scheme for obtaining money through the mails by means of false and fraudulent pretenses, and recommended that a fraud order be issued. The Postmaster General closed the United States mails to these concerns on January 11, 1936.

The postoffice inspectors are to be congratulated on bringing to a close this particular vicious piece of quackery—an exploitation directly to the public of a secret nostrum for reducing which obtained such effects as were secured primarily by its content of dinitrophenol, a drug already established as potent for harm.

## Correspondence

### DIPHTHERIA WITH SCARLET FEVER

*To the Editor*—A boy, aged 6, was seen February 23, at which time a diagnosis of scarlet fever was made from the typical history and appearances. The temperature was 102 F, the throat was red with markedly enlarged tonsils, and a bright rash was present. February 28 a follicular tonsillitis developed; the temperature ranged between 101 and 103 F. March 2 the follicles became confluent to form a membrane, which covered both tonsils. The membrane appeared like the usual streptococcic membrane—bright yellow. It did not appear or behave like a diphtheritic membrane. A culture, however, was taken after great effort, the patient being very uncooperative. This culture came back unsatisfactory. A second culture taken came back positive for diphtheria bacilli, which were subsequently shown to be virulent by a virulence test. Antitoxin was then administered, 10 000 units followed in twenty-four hours by 5 000 more. It was given intramuscularly. No antitoxin was given at the time the culture was taken because it was felt that the membrane was of streptococcic origin and because the mother claimed that, at the age of 3, the boy was immunized with three doses of toxin-antitoxin and was negative to the Shick test. This was verified by communication with the doctor who did the immunization.

With the appearance of the membrane, the temperature ranged from 100 to 101 F. The day before the administration of antitoxin there was a bloody discharge from the mouth. The temperature dropped to normal and the membrane disappeared following the administration. At present there appear to be no sequelae from either the scarlet fever or the diphtheria. Subsequent cultures from the nose and throat were negative for diphtheria bacilli. All laboratory work was done by the branch laboratory of the state department of health.

Diphtheria coexistent with scarlet fever is about one in every ten thousand cases. This case serves to remind us that the immunity conferred by toxin-antitoxin or toxoid is only relative and not absolute, that a bloody discharge from the nose or throat should always suggest diphtheria and that it is important to take cultures on all membranes and to administer antitoxin.

ALEXANDER ZABIN, M.D., Malverne, N. Y.

### BARBITURATES AND IRRADIATION

*To the Editor*—On page 1236 of THE JOURNAL, April 4, appears an abstract of Uhlmann's paper "Roentgen Reaction Elicited by Medicament" (*Deutsche med. Wochenschr.* 62:216 [Feb. 7] 1936). While "on the basis of the clinical manifestations a medicinal toxicoderma was thought of" and a history of the ingestion of barbituric acid derivatives was elicited, the author did not bring out the fact that barbiturates and the barbituric acid derivatives produce porphyrimia and porphyrinuria and therefore cause sensitization to light. Porphyrinemia and porphyrinuria cause a sensitization of the skin (and probably other tissues) to irradiation; consequently it is advisable that patients who are to be subjected to roentgen or radium therapy should not be given any of the barbiturates or their derivatives. I have seen two instances of what were to all external appearances roentgen erythemas, one of which had been diagnosed as 'x-ray burn,' but which were due to 'sleeping tablets' taken by the patients at the same time that the roentgen therapy was received. These did not recur when the phenobarbital was discontinued even though the x-ray dosage was increased in one case.

I. S. TROSTLER, M.D., Chicago

### LEUKEMIA WITH THROMBOCYTOSIS

*To the Editor*—A case report on leukemia with thrombocytosis by Dr. Carl C. Drake (THE JOURNAL, March 2, p. 1005) omits two important points: first, the mechanism of bleeding in thrombocytosis and, second, the commonly occurring diseases with unusually high platelet counts.

The paradoxical bleeding in the presence of unusually high platelet counts is due to vascular injury from embolic phenomena rather than to any diminution in the blood clotting function. This interpretation with a case citation of 1,300 000 platelets per cubic centimeter was given in my paper on the management of hemorrhagic problems in infancy and childhood (THE JOURNAL, Sept. 10, 1932, p. 895).

Primary thrombocytosis, or thrombocythemia, was first described by Pianese in *Haematologica* (1:61, 1920), simultaneously by di Guglielmo (*ibid.*, p. 303) and subsequently by other observers as indicated in Dr. Drake's report. Secondary thrombocytosis is prevalent in polycythemia, lymphogranulomatosis and chronic myelosis. Marked increase in platelets is due to diminished destruction by the spleen, as demonstrated more recently by Epstein and Goedel (*Virchows Arch. f. Path. Anat.* 292:233, 1934). Tissue injury by severe infection or surgical trauma stimulates the production of platelets independent of other blood cells. Thus mere thrombocytosis is no criterion of latent leukemia.

I. NEWTON KUGELMASS, M.D., New York

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

### TREATMENT OF ARTHRITIS BY BEE VENOM

*To the Editor*—I will appreciate it if you will advise me as to the treatment of arthritis by bee venom therapy as advocated by Beck in his book published by the D. Appleton Century Company.

PARKS M. KING, M.D., Charlotte, N. C.

*ANSWER*—The idea that rheumatism of various kinds can be cured by bee stings belongs to folk lore and is found in the earliest medical writings. Attempts have been made from time to time to place this form of treatment on a scientific foundation, but it has been abandoned many times, only to be revived by the persistent testimony of bee keepers and laymen. Almost without exception, medical reports have been inadequate, even if interesting—inadequate because little if any attempt has been made to study the subject scientifically, to present controls or to classify accurately the type of rheumatic diseases treated. The terminology used in most of these reports (and also that by Beck) is most indefinite and indicates a lack of real familiarity with the diseases concerned. Thus the terms "rheumatoid heart affections," "endocrine polyarthralgia," "arthritis deformans," "arthritis" and "cases of true rheumatic origin" are used repeatedly without definition.

Beck expressed the opinion that the venom therapy has been abandoned repeatedly only because of difficulties inherent in the use of live bees. This difficulty is now obviated by the availability of commercial preparations of bee venom: apiscan, immenin, and apisin and British bee venom. By his review of the rather voluminous literature that has appeared on the subject during the past seventy-five years, and by his presentation of a collection of testimonials from bee keepers and laymen, Beck has attempted to "stimulate the medical profession to take this effective remedial agent out of the hands of the laity" and to prove that almost all true arthritis and rheumatism can be radically and permanently cured by bee stings. But just what is "true arthritis"? What are cases of true rheumatic origin and just what is a "radical cure"? The author exhibits a marked lack of critical appraisal of his bibliographic material; accepts statements regarding "marvelous results" without question; and when a bee keeper writes that he or a friend was cured of rheumatism by bee stings, the letter assumes the importance of a scientific certified document.

According to Beck, rheumatic conditions are "due to a local relative state of suboxidation produced mainly by an impaired

circulation" caused by "vasoconstriction of sympathetic nerve endings" (Since when have nerve endings vasoconstricted?) Thus, "tissue anemia is the cause of arthritis," and the pathologic explanation of rheumatism and of arthritis is the accumulation (suboxidation) of lactic acid in affected tissues. The therapeutic value of venom presumably is mainly the result of its hemorrhagic property, it contains an endothelotoxin (hemorrhagin) which causes capillaries to become permeable to blood. By accelerating and intensifying circulation and by dilating capillary vessels, bee venom enables blood cells to transmute into tissues. The physiologic effect of bee venom is therefore, according to Beck, comparable to histamine, which currently has been advanced by some for the treatment of various rheumatic diseases.

These ideas on the etiology and pathology of rheumatic diseases are not in accord with those accepted by the greater number of writers on the subject and are apparently borrowed from other writers with no support from the author whatever. (In an attempt to find some clearer exposition of Beck's point of view, other statements by him on bee venom or on rheumatic diseases were looked for in the *Cumulative Index Medicus* from 1916 to date but no article by him on any subject is listed.) The gross error in Beck's presentation is that he has omitted entirely any details of his own experience with treatment. Not a single record of a personal case is included, no statistics of his own results are given, and no controls are presented. His case is made up entirely from the generally unscientific and, therefore, unacceptable writings of others.

It is stated that patients with "arthritis and rheumatism" possess an unusual or pathologic immunity to bee venom but that patients with tuberculosis, syphilis and gonorrhea are unusually sensitive to it. In spite of the arthritic patient's unusual immunity, it is repeatedly stated that the results from injections of bee venom in arthritis arise through the production of a slow, gradual, progressive and comfortable immunization. It is not made clear to the reader how one can immunize a patient who is already immune. A variety of diseases presumably are successfully treated. According to Beck, bee venom therapy is almost specific for rheumatic fever and endocarditis, its results are 'very good' in Bechterew's spondylitis. It is indicated in rheumatoid arthritis, myalgia, myositis, neuritis, migraine and even traumatic arthritis. It will also cure acute and chronic gout (presumably also the result of suboxidation). There is not the slightest original proof by Beck in support of most of these statements. A sentence here or there permits one to suspect that all is not as painted. Although infection is considered a minor factor in the production of rheumatoid arthritis, Beck said "the removal of infected foci will be only too helpful." Beck's description of the plan of dosage, of the technic of administration and of the reactions to be sought or avoided are inadequately and unclearly presented. The questioner is referred to the book. Beck unfortunately leaves the problem just about where he found it. Certainly, the place of bee venom therapy in rheumatism, particularly in the treatment of rheumatic diseases, is not materially strengthened by this book. It may have some value but it still remains for some one else to demonstrate this scientifically.

#### POSSIBILITY OF LEAD POISONING FROM SPRAYED APPLES

To the Editor—The assistant at the U. S. Entomological Laboratory at Carlisle, Pa. makes the statement that there may be enough lead in sprayed apples even after they are pared to give symptoms of lead poisoning to those eating them. Will you tell me whether this statement is in line with authoritative opinion? Please omit name.

M. D. Pennsylvania

ANSWER—Instances of lead and arsenic poisoning have been reported which were believed to be due to the ingestion of fruit and vegetables that had been sprayed with insecticide. C. N. Myers and his associates at the Stuyvesant Square Hospital, New York, examined specimens of a large number of fruits and vegetables obtained from the open market in the fall of 1932 to determine the amount of arsenic and lead present. Their results were published in *Industrial and Engineering Chemistry* (25:624 [June] 1933). In the specimens of apple pulp examined, the amount of lead present varied from 0.38 to 1.8 mg per hundred grams of solids of the specimen. In the specimen of apple core examined the amount of lead present varied from 16 to 199 mg per hundred grams of solids present in the specimen. The amount of lead present in the unwashed apple skin in the specimens examined varied from 0 to 8.36 mg per hundred grams of solids in the specimens. Various commissions in different countries have considered the minimum amount of lead and arsenic remaining on fruits that have been sprayed, and in April 1933 the Food and Drug Administration

announced that 0.014 grain per pound, or 2 parts of lead per million would be permitted, and that the arsenic would remain at  $\frac{1}{100}$  grain per pound, or 14 parts per million of As<sub>2</sub>O<sub>3</sub>. These figures are said to agree with those set up by a British royal commission dealing with a similar problem. While Myers and his associates feel that the spray residue situation menaces the general well being the available evidence indicates that the consumer need not ordinarily fear acute poisoning when he eats fruit or vegetables. However, it is well to wash thoroughly and to cleanse such materials before putting them on the table in either the raw or the cooked form, and perhaps to strip and destroy the outer layers of lettuce, cabbage and similar vegetables that lend themselves to such manipulations. This subject was discussed in an editorial in *THE JOURNAL*, July 8, 1933, page 126.

#### TRICHOMONAS VAGINITIS

To the Editor—The physician who has a properly powered microscope in his office and uses it on all chronic vaginal discharges is finding plenty of *Trichomonas vaginalis* beyond all expectations when he started his profession a few years ago. The doctor not microscopically equipped so as to examine fresh smears cannot do justice to his patient for I find this disease one of the most intractable of the female complaints that come to the physician. Therefore I am asking what you consider the most effective of the various methods used to combat the malady just how do you apply the treatment and how long do you think the average case will have to stand by before the doctor can proclaim the patient cured beyond a doubt? Again I find patients coming to me who are accommodating their husbands right along. If he does not resort to the toilet after intercourse with plenty of soap (or none at all) where does he get off as a carner? Also what becomes of the parasite on his sexual organs? In spite of the soap pyrolytic acid Laszlar's paste treatment which I mostly use some are mighty stubborn to yield and the time to get final results is considerable and the expense is worse. So this is why I am anxious to canvass the results of your experience to see whether you can recommend anything better than I am using. Have you heard that brine (saturated solution of salt) will beat all other remedies of the past—a recent one sprung on me? If so how do you use it? Kindly omit name.

M. D. Maine

ANSWER—There can be no dispute that *trichomonas vaginitis* is commonly observed in gynecologic practice. The clinical picture and nature of the discharge are so characteristic that the alert physician will readily recognize the condition. The microscopic examination of fresh vaginal secretion diluted with physiologic solution of sodium chloride or even with distilled water is the most immediate means of corroborating the presence of the protozoa. Every physician who practices gynecology should be equipped to establish the correct diagnosis in cases of vaginitis and genital infections in general. There is no specific treatment of *trichomonas vaginitis*, nor can there be so long as there is as yet no unanimity of opinion concerning the pathogenicity of *Trichomonas vaginalis*. Many different plans of treatment have been described, ranging from the radical 'soap scrubs under general anesthesia' to the simple vaginal irrigation with hypertonic salt solution or even with large quantities of plain tap water. Goodall reported specificity for the treatment with 1 per cent trinitrophenol in vaginal suppositories containing oroglyceride and other medicaments, followed by vaginal douches. However, many American clinicians have observed that recurrence frequently followed this as well as other forms of treatment. Some women are relieved by a single or at most a few local treatments, while others suffer repeated recurrences, notably after the menses. In severe forms, several months' observation is required in which to make check-up examinations, and smears following each menstrual period are necessary to establish the fact of cure. A form of treatment that has yielded a high percentage of cures is the following. After the fresh smear has revealed the presence of pus and large numbers of active trichomonads the vagina is thoroughly washed with tincture of green soap with a large cotton swab or preferably with gauze. This is rinsed with water dried and then swabbed with 1:5,000 solution of potassium mercuric iodide and again dried. A gauze sponge (Handy-fold sterile gauze) soaked in glycerin is then packed into the vagina and left for twenty-four hours. The patient is instructed to wear a pad as the hygroscopic action of the glycerin causes a profuse watery exudation. On removal of the gauze pack, an irrigation is taken in the recumbent position with 4 cc of lactic acid (U. S. P.) to each liter of warm water. For aggravated cases, two or more liters should be used twice daily. The treatment is repeated every second day for three or four applications until relief is noted and the appearance of the vaginal mucous membrane is normal. The irrigations are continued throughout the months until menstruation appears. Some clinicians even advise their use during the period. After menstruation and at least forty-eight hours after the last irrigation a smear is taken and a soap-glycerin treatment is given. If there has been no recurrence, the patient may simply use

home irrigations daily and return after the next period. On the other hand, if recurrence is noted, three treatments are given as before. This procedure should be repeated monthly for about six months. Even then, recurrences or reinfections may occur from time to time. As the source of trichomonas infection is unknown, one cannot advise concerning adequate prophylaxis. There is insufficient evidence at hand that the husband is a source or carrier of trichomonas infection. The parasite dies quickly on drying. Urethral and prostatic secretions in the male yield *Trichomonas* only in a small percentage of cases.

#### HAZARD FROM METAL FOIL ON CHOCOLATE

*To the Editor*—Will you kindly have me informed if there is any evidence that the metallic foil used as a wrapper about chocolate and candies (as Hershey's or Wilbur's chocolate huds) is injurious to the consumer? They sometimes do have a metallic taste.

CHARLES STOVER, M.D., Amsterdam, N. Y.

*ANSWER*—Metal foils used as wrappers long have been regarded as having a high lead content. Some foil wrappers for tea contained (1921) from 40 to 48 per cent of lead, the remainder being mostly tin. At that time foils for cheese contained approximately 92 per cent tin, 7 per cent lead and 1 per cent copper. In 1921 the most commonly used foil was made up as follows: Tin, 96.21 per cent, copper, 0.95 per cent, lead, 2.41 per cent, iron, 0.09 per cent, nickel, 0.30 per cent. At the present time a typical foil such as for cheese contains 96.8 per cent tin and 3.2 per cent antimony, together with a trace of iron. In addition to tin foil, much aluminum foil is in use. The high resistance of aluminum foil to corrosion is said to be due to the presence of a nonporous adherent oxide film. For many purposes metal films are lined with paper as a barrier between the metal and the food or other substance within the wrapper. Likewise certain foils are coated with lacquers or related chemicals, also to avoid direct contact between the metal and foods. Although there has been much agitation over aluminum as a toxic substance, little reason exists for believing that small quantities accidentally ingested as a foil may be regarded as harmful. This statement also applies to tin. At this time the content of lead in domestic foils is so low as to introduce no large hazard. The presence of antimony may be regarded with suspicion, but here again no evidence is at hand indicating injuries to consumers. It may be maintained that foils used as wrappers for foods may be regarded as dangerous in proportion to their content of lead and antimony, and in proportion to the extent that they enter the body either as foil or in solution after contact with food or otherwise.

#### INDUSTRIAL HAZARDS OF WELDING

*To the Editor*—Please advise me of the industrial hazards of electrical welding with covered rods. A patient comes to me with the following story. He and his father operating a machine and welding shop purchased some welding rods under the trade name of Rego No. 333 A. These rods smoked profusely when used and seemed to cause headaches. The patient's father after working all day using these rods complained of headaches and severe pain in the chest and died about midnight. The attending physician stated that his death might have resulted from the smoke or fumes generated in the welding process. The patient, a well developed, well nourished man of 26 states that he has pains in the anterior chest region and believes them due to using these welding rods. Physical examination reveals nothing abnormal. He states that he was examined by a specialist in the city about a month ago with no abnormal observations. The patient believed that the death of his father resulted from using these welding rods. L. M. DILLMAN, M.D., Houston, Mo.

*ANSWER*—Early death after exposure to the gases and fumes from welding operations is fairly frequent. Death and illness are not associated with any particular type of rod or any particular coating. Products of any one manufacturer are not known to be more dangerous than those of other manufacturers producing similar material. For these reasons it is unwise that this reply should be directed especially to the one product named. It is believed that specific information on this product can be obtained from the Weldcraft Equipment Company, Pittsburgh, or the Bastion Blessing Company, 240 East Ontario Street, Chicago. Further portions of this reply are with reference to the hazards of welding in general. A fatality following electrical welding with coated rods is reported by Willman (*J. Indust. Hyg.* 17:129 [Jul.] 1935). In this instance the welding was on galvanized iron and undoubtedly the fumes contained both zinc and iron. Under other conditions of exposure such other metal fumes as copper, cadmium or lead may arise. Carbon monoxide may arise during welding work as cited by Schwarz in accounting for the death of two workmen doing oxyacetylene welding (*Zentralbl. f. Gewerbehyg.* 6:3 [April] 1929). Another death is reported by Holzmann

in the last cited journal (5:233 [Aug.] 1928). In addition to the hazards already mentioned, acetylene may contain arsenic and phosphine toxic impurities. The most encountered action attributable to welding gases and/or fumes is metal fume fever, characterized by low grade respiratory irritation, malaise, chills, anorexia and nausea. The direful cases are prone to arise from edema of the respiratory tract, pulmonary hemorrhage or promptly developing pneumonia. There are good reasons to believe that welding gases may occasion acute cardiac episode, or may at least acutely aggravate preexisting cardiac conditions. The death of this workman in fact might be linked up with his employment as described by the information made available, but the information does not permit a definite stand against the particular product mentioned or against welding in general.

#### EFFECTS OF RADIUM ON TISSUE OF FEMALE GENERATIVE TRACT

*To the Editor*—Two years ago last summer I sent a patient to the hospital for radium for a moderate sized fibroid accompanied by profuse hemorrhages. The profuse hemorrhages ceased following the radium but occasional fairly regular short menstrual periods with scanty flow have occurred since that time. The pelvic mass has grown smaller and the general health of the patient has greatly improved. About six weeks ago following a scanty flow a vaginitis developed the mucosa was red and swollen but rather dry and there was no discharge whatever. This condition improved but after a certain amount of improvement it seemed to remain fairly stationary. Hot douches made it worse. Local applications of neo-silvol brought about considerable improvement. There is some sagging of both the anterior and the posterior vaginal walls with moderately poor perineum. Most of the soreness and swelling at present seem to be on the posterior vaginal wall and the patient complains of soreness when she sits in a chair. Being on her feet a long time seems to make her feel worse but she complains frequently of feeling worse in the morning than she does at night. Now I suspect this is one of those types of vaginitis which come near the menopause and is rather persistent to deal with. I should like to ask whether the use of radium has anything to do with it. I should also like to ask what treatment would be suggested. Has amniotin or similar preparations proved efficacious in this type of vaginitis? Please omit name. M. D. Ohio.

*ANSWER*—Subsequent to radium treatment there is frequently an obstruction of the cervix with more or less complete retention of secretion. The retained material is highly irritating and when it escapes into the vagina even a small amount of secretion may produce intense burning. Most patients who suffer from vaginal discomfort from this cause give a history of slowly established or prolonged brownish menstrual flow, and attempted passage of a small Hegar dilator may reveal a cervical obstruction.

Dryness of the vagina ascribable to menopausal decreased endocrine activity may also cause irritation. In such cases the oral administration of estrogenic substance may bring relief.

Despite the apparent absence of a discharge *Trichomonas vaginalis* vaginitis or infection with other organisms should be ruled out by examination of fresh material as well as by stains of the vaginal secretion.

#### TESTS OF ACIDITY AND ALKALINITY OF URINE

*To the Editor*—Kindly give me the technique for the use of methyl red and thymolphthalein in testing the acidity and alkalinity of the urine and the significance of the result of such tests.

J. HOWARD GOULD, M.D., Ridgewood, N. Y.

*ANSWER*—A search of the literature has not revealed any article advocating the use of the two dyes methyl red and thymolphthalein for the determination of acidity and alkalinity of the urine. However, similar dyestuffs are used both in the form of "mixed indicators" and individually for the determination of hydrogen ion concentration.

One such mixed indicator, advocated by Moir in 1917, contains methyl red and naphthol phthalein and phenolphthalein. Another, described by Niklas and Hock, "one volume 0.04 per cent bromcresol purple, four volumes 0.04 per cent bromphenol blue, six volumes 0.02 per cent methyl red and four volumes 0.04 per cent bromthymol blue," has a range of from 3.5 to 7.6. Felton used equal parts of methyl red and bromthymol blue for the range 4.6 to 7.6 (unsatisfactory between 5.6 and 6.2), methyl red and bromcresol purple 4.6 to 7.0, methyl red and thymol blue (rough) 1.2 to 9.0.

More detailed information concerning these indicators can be found in Clark's "Determination of Hydrogen Ion Concentration" third edition, 1928, page 97. In this volume, as well as in Peters and Van Slyke's, "Quantitative Clinical Chemistry," the exact procedure may be found for the use of various dye stuffs for the colorimetric determination of the hydrogen ion concentration of urine in accordance with the methods of Hastings and of other workers.

DERMATITIS—CASTOR OIL—ADMINISTRATION OF  
POTASSIUM IODIDE

To the Editor—1 I have a patient with a moderate sized patch of chronic eczema on the back of the neck of some years duration. I have tried U S P pine tar ointment and lately full strength U S P chrysarobin ointment locally and have succeeded in stirring up no reaction whatever except over a ring of normal surrounding skin. Can you suggest any other local applications or treatments of any sort that might stir up this chronically diseased area and thus stimulate formation of more normal outgrowing skin? 2 On page 53 of the second edition of *Useful Cathartics* edited by Fantus the statement is made that because of thoroughness and reliability of action it [castor oil] is the purgative of choice for delicate invalids and infants in pregnancy. Does Dr Fantus mean only in early pregnancy or does he mean that the terrible fear of most doctors and laymen concerning the use of castor oil in pregnancy (and especially in late pregnancy) is unfounded? Being somewhat surprised at seeing this some time ago in my cathartic bible I would like some elaboration on this statement. 3 How is potassium iodide best administered so as not to leave an after taste? Is there not a more palatable form in which to administer opiates to infants than paregoric? Paregoric smells good but is strong and gags almost any infant. Diluting it with water seems only to prolong the agony. Or perhaps my experience has been unusual. Is infant tolerance to morphine more proportional to fraction of weight or of age or of both as compared to adult dosage? Are infants relatively more or less tolerant to morphine than adults or proportionately about the same?

THOMAS GRAY HARVEY MD Maine

ANSWER—1 such an area of dermatitis needs stronger applications than these official ointments, which are merely of such strength as to suit the average case. The N F solution of coal tar, for instance which for average use needs to be diluted with 10 parts of water, might be employed in such case as the one cited in greater concentration, even up to full strength. 2 Castor oil may safely be given with caution in ordinary doses as a laxative even in late pregnancy.

3 The 'after-taste' of potassium iodide is largely due to its elimination in the saliva. It is best mitigated by taking frequent drafts of fresh cold water or of fruit juices. A palatable method of administration is to give the syrup of hydriodic acid in cherry syrup. The aromatic syrup of eriodictyon is probably the best disguising vehicle for children's doses of alkaloidal drugs. Dosage for morphine as well as for other drugs should be proportionate to weight rather than to age. It has lately been shown (Irish, H E. Dosage of Camphorated Tincture of Opium and Morphine for Infants, *Am J Dis Child* 49 1503 [June] 1935) that the dose of morphine for children is about the same in relation to body weight as the dose for adults.

## HYPOSENSITIZATION TO TRICHOPHYTON

To the Editor—I have been treating a case of trichophytosis of the feet several months. The patient is a youth aged 20. This condition has persisted for six years. Acute exacerbations occur during the summer. At those times both feet and forearms also the hands are covered with tense small vesicles containing clear fluid. After they break open a raw beefy surface remains. The patient has been treated in numerous clinics to no permanent avail. The condition will almost clear up and then break out into renewed ferocity. I have the condition quiescent now but my hair is becoming gray over the possibility of a relapse. I used potassium permanganate and resorcinol solutions continuous wet dressings. Have you heard of desensitizing such people by trichophyton preparations? Are there vaccines or any kind of preparations to do such a thing? My subject is probably reinfesting himself and hypersensitive. If your answer is yes please tell me what you can about it and where to obtain it.

EDWARD MARTIN REPP MD Philadelphia

ANSWER—If the demonstration of fungi in the foot lesions and if the other essential criteria strongly favor the assumption that the condition is a true trichophytosis and trichophytid—dermatophytosis and dermatophytid—and if the trichophyton and/or oidium reaction is strongly positive hypsensitization with fungus vaccines may be attempted in such a persistent and therapeutically refractory case. However this immunologic therapy should not be essayed until all conceivable contact causes (shoe leather, polishes, socks dyes, plants) have been eliminated as far as possible by history and by negative patch tests. Furthermore immunotherapy should not be considered until all ordinary local therapeutic measures have been tried to no avail.

If hypsensitization procedures are resorted to satisfactory results have been reported to have been obtained by the combined use of monilia and trichophyton extracts. The Council on Pharmacy and Chemistry in a preliminary report on Trichophyton Extract (Metz Trichophyton) (*THE JOURNAL* Nov 19 1932 p 1779) stated that the clinical evidence from American dermatologists was not sufficient to justify acceptance of the product for New and Nonofficial Remedies at that time. The Council's decision on Trichophyton extracts is confirmed by Traub E F and Tolmach J A. Dermatitis trichophytosis. Its Treatment with Trichophyton. *Arch Dermat & Syph* 32 413 (Sept) 1935, abstr *THE JOURNAL*, Oct 26 1935 page 1382.

The immunization procedure must be carried out with great care and must be begun with very small doses.

The method and the chances for successful hypsensitization as well as the difficulties and some of the probable reasons for failure are adequately described in the following publications.

VanDyke L S Kingsbury Jerome Throne B and Myers C N Use of Trichophyton As Diagnostic and Therapeutic Agent in Mycotic Infections of Skin. *New York State J Med* 31 611 (May 15) 1931

INDUSTRIAL HAZARDS IN MANUFACTURE OF  
FLASHLIGHT BATTERIES

To the Editor—Kindly inform me of the industrial hazards to workers employed in the manufacture of ordinary flashlight batteries. A woman aged 27 employed during the past twelve years in the manufacture of flashlight batteries complains of persistent pain of moderate intensity localized over an area 3 inches in diameter just below the right scapula. Physical examination of the chest is essentially negative. There is a slight productive cough but repeated sputum examinations have been negative for tubercle bacilli. Roentgen examination of the chest shows that the pulmonary fields are of almost equal size and illumination and that both hili are moderately infiltrated are fibrotic in appearance and contain a number of glands. The radiating bronchi and linear markings are accentuated but do not contain any studdings along their course. There is a congestion of the bronchial tree. There is no evidence of any Koch infection or pneumoconiosis. There is no loss of weight or strength or elevation of temperature. Please omit name.

MD New York

ANSWER—In dry batteries the negative pole consists of a zinc container into which is placed a mixture of carbon ammonium chloride and manganese dioxide. These chemicals may or may not be contained within paper or muslin bags. The positive pole is a carbon rod inserted into the middle of the container. These containers when properly filled are sealed over with "sealing wax," rosins or tars, and are fitted with brass binding posts. The chief substances to which significance has been attached as health hazards are manganese dioxide, lead as used in solder, mercury as used in amalgamation carbon compounds, chromium compounds benzene and related hydrocarbons, hydrochloride or other mineral acids arsenic as an occasional impurity, zinc chloride ammonium chloride, rosins and tars as used in sealing over the top of the battery. Wheat flour and potato starch occasionally lead to skin sensitization. Dry battery making long has been regarded as a dusty trade. Tuberculosis at least a score of years ago, was regarded as prevalent in this industry. Occupational cancers have been attributed to the tars and pitches used in this trade and also to impurities in the carbonaceous materials employed. Neoplasms along the respiratory tract have been mentioned but the entire matter of occupational cancer in this trade has not been well authenticated. The pulmonary disorder described is not a well known result of any known exposure in dry battery manufacture but it is recognized that the dusts of this dusty trade conceivably may have played some part in the causation of this disorder.

EFFECTS OF DIATHERMY ON LIVER CELLS IN  
PERNICIOUS ANEMIA

To the Editor—Since Crile has used diathermy for stimulation of the liver cells before and after operation for prevention of shock would it be likely that the use of the same treatment would be instrumental in effecting an increase of red blood cells by treating the liver or the other blood forming centers? In a brief way what is a suitable outline of diet in a person with pernicious anemia and diabetes together? Please omit name.

MD Kansas

ANSWER—The use of diathermy for stimulating an increase of red blood cells by treatment of the liver or over the bone marrow in order to stimulate blood formation has not been reported on. It seems rather doubtful that this method of treatment would be attended with any success, owing to the nature of the disease process in pernicious anemia. There is apparently a deficiency of the antianemic substance attended by a failure to store the material properly rather than evidence of failure of utilization after storage in the liver.

Diathermy has been used in pernicious anemia in an effort to improve the disturbances resulting from subacute combined system disease but this has not been attended by success although its effect on blood formation has not been noted. Whether or not it might be useful in stimulating blood formation in certain of the other anemias is problematic and no doubt this problem should be studied.

Regulation of the diet of a person with pernicious anemia and diabetes mellitus is to be based on the principles of regulation for the diabetic patient and without consideration of the anemia. The pernicious anemia will be controlled by an ade-

quate intake of liver or an effective substitute either orally or parenterally, whereas these substances will not in any way interfere with the usual dietary regulation for the diabetic patient. If whole liver is used, this may be calculated into the diet just as any other meat is. It has been shown that whole liver and certain extracts of it have a mild insulin-like effect in certain cases of diabetes, and the diabetic condition is generally a mild one when it occurs with pernicious anemia, possibly because of the age of the patient. It would therefore be desirable to carry out dietetic treatment either with or without the use of insulin and in accordance with any of the standardized methods.

#### LIVER DAMAGE AND HYPERGLYCEMIA

*To the Editor*—I have a patient who discovered she was diabetic about twenty years ago. The blood sugar has been as high as 750; she has been on the verge of coma several times. She had a gangrenous foot that was months in healing and the urine has not been sugar free for years. She has been on insulin and a diet but in rather a haphazard manner. About three weeks ago she had an acute illness with chills and fever. At that time the urine was found to be sugar free. The blood sugar was 250. The urine still continues to be sugar free and today the blood sugar was 125. She has chills periodically similar to malaria chills but there is no malaria in this district and the patient has no further symptoms of malaria. At first I attributed the chills to insulin shock but they have continued over a period of approximately three weeks during which she has had no insulin but they are gradually diminishing in severity and I have every reason to believe that the patient has not adhered strictly to her diet yet the blood sugar is gradually coming down to normal. The patient is 69. Ordinarily her blood pressure is 225 but it has also fallen to 150. There is no apparent loss in weight or marked change in her physical condition. I am at a loss to know what has brought about this change in her system and wish to ask if you have any such cases on record in which a person with chronic diabetes has had sugar free urine when disregarding the diet.

DANIEL I. MARKER, M.D., St. Mary's, Kan.

*ANSWER*—It is known as the result of hepatectomy experiments that the liver is the sole source of the blood sugar in the absence of food" (*Am J Physiol* 81:382 [July] 1927). It has also been shown that this is just as true for the diabetic organism as for the normal (*Arch Int Med* 31:797 [June] 1923). It follows that sufficient damage to the liver parenchyma, by decreasing the capacity of the liver to supply sugar to the blood, may cause a decrease in the diabetic manifestations and apparent improvement of the diabetes. In extreme cases even hypoglycemia may result. Such instances have been reported by Zeckwer (*Arch Int Med* 54:330 [Sept.] 1934). Improvement of diabetes has also been reported coincident with a hypophyseal disturbance (*Lancet* 1:318 [Feb. 9] 1935).

#### CARE DURING THE MENOPAUSE

*To the Editor*—I would appreciate exceedingly any suggestions you can make as to the treatment of the distressing nervous symptoms in many women at or near the menopause. I am particularly interested in this just now because my wife who is 42 years of age, is having that experience. The amount of flow is getting less all the time. She has never had children although she has had two or three miscarriages. She has a mucous colitis but this does not seem to be very bad. She has splitting headaches and at times a feeling as if something were grinding in her head. When I say splitting headaches I mean just that kind. It seems as if the head were going to burst open. The headaches have to a considerable extent improved under four to five day injections of corpus luteum extract but this does not seem to affect the nervous element. She has a kidney infection and when it flares up it increases the whole train of symptoms.

M.D., Arizona

*ANSWER*—A careful and thorough physical examination should be made to try to determine the cause of the severe headaches. If no etiologic factor can be found, it may be assumed that the headaches are linked up with the menopause. However, 42 is an early age for the change of life. Many women can be relieved of at least part of the distressing symptoms that occur during the menopause by the administration of estrogenic substance. The chief American preparations of this substance are theelin (Parke, Davis & Co.) and aminotin (Squibb). It is best to give about 400 or 500 rat units of these substances hypodermically three or four times a week. To receive a similar effect, the amount taken by mouth must be about five times the dose administered hypodermically. The amount of estrogenic substance given to a patient should depend on the amount of relief obtained. The more the disturbing symptoms are relieved, the smaller and more infrequent may be the doses given. Furthermore regardless of how much estrogenic substance is given to the patient a mild sedative should be prescribed for daily use, because it is most helpful. Recently reports have appeared claiming that severe headaches in many instances may be relieved by the hypodermic administration of ergotamine tartrate and by the oral use of chondroitin sulfate.

#### SAFETY PERIOD FOR CONTRACEPTION

*To the Editor*—May I enlist your aid in a case of a married woman aged 26 desiring to use the safe period of contraception? For the past ten months her periods have been as follows: January 20, February 7, March 21, April 17, May 16, June 16, July 14, August 19, September 14, and October 16. Every period of the last ten months has lasted but 11 days. I have attempted to determine the safe and fertile periods according to the article of Latz and Reiner in the Oct. 19, 1935 issue of *THE JOURNAL* but I am somewhat confused. Their article states that the fertile period extends from the twelfth to the nineteenth day before the expected menstruation (the expected first day of menstruation being calculated from the longest cycle in the last eight months) plus the days of variation between the longest and the shortest cycle in the last eight months added to the beginning of the fertile period. Now the patient about whom I seek advice has a short cycle of twenty-seven days and a long cycle of thirty-six days which should make a fertile period of seventeen days—eight days natural fertility plus nine days variation—yet in chart 3, page 1243, a woman with a twenty-seven to thirty-six day cycle has a fertile period of but fourteen days. Would you kindly set me straight in this matter of safe periods and give the fertile and safe periods of the patient to whom I have referred? Please omit name.

M.D. Pennsylvania

*ANSWER*—In cycles of twenty-seven to thirty-six days, the period of fertility lasting seventeen days is correct as the corresponding computed it. By referring to chart 1 on page 1241 of *THE JOURNAL* of October 19, it will be seen that the computation of seventeen days of fertility conforms to the conception period for twenty-seven to thirty-six day cycles, as expressed in this chart. Chart 3 is a compilation of intercourses occurring outside the fertile period, which did not result in pregnancy, and was not intended to express the duration of the fertile period.

The apparent discrepancy arises from the fact that women are advised as an additional precautionary measure to abstain two additional days after the fertile period and one extra day before the period, as shown in chart 1. Chart 3 shows the intercourses had in reference to the fertile period as outlined by Knaus.

#### VASCULAR CHANCES IN LEGS

*To the Editor*—A man aged 76 active and in good health, has never been seriously ill except for pneumonia when in his twenties. At present he complains of a feeling like needles in his right foot all of the time but of varying intensity. This has been present for two years and is improved by exercise and by raising the extremity above the level of his body when in bed. If the foot gets in a dependent position the needle pain will wake him up sometimes with cramps in the calf. The other foot is only slightly affected. Heat seems to benefit the condition temporarily. Physical examination shows a good pulse in the arteries of the ankle and knee. No sclerosis is present. The reflexes are normal. The foot is cool and there are no red spots or abnormal colorations present. Sensation is normal in the calf. The condition is worse in cold weather. Please omit name.

M.D., Wisconsin

*ANSWER*—The patient apparently has a vascular disturbance in the lower extremity. The condition as described is not compatible with an involvement of the peripheral nerves. It is quite likely that the condition is one of senile changes in the deeper vessels of the lower extremities rather than one of a functional vascular disturbance. It is unlikely that any treatment would be of much help except maintaining the limbs in an elevated posture.

Contrasting hot and cold baths may be tried.

#### HEMOPHILIA IN WOMEN

*To the Editor*—I should like to get the latest information on hemophilia in women. I have in mind the case of a married woman whose mother bore four children, two daughters and two sons. All four lived and all have children. One son the woman's brother definitely has hemophilia. He has three children. The two grandmothers were sisters. So far as she can remember the woman knows of only one uncle who has hemophilia. She wants to have children. What is the best information in the literature now available that would serve as a basis for advising her? She herself does not believe that her mother had hemophilia but is eager to know what chance there would be of her transmitting it to her own children.

GEORGE GAAL, M.D. Chicago

*ANSWER*—The patient's mother did not have hemophilia, because this disease is restricted to the male sex. The few cases in which female bleeders have been reported as hemophiliacs have not presented enough evidence to justify the diagnosis. On the other hand, the disease is transmitted by women but only to the male members of the family. Hemophilia occurs in the male offspring of families through many generations, but not all the male members of any one generation are necessarily affected. Not infrequently the disease appears early in life, at birth when the umbilical cord is cut. Many cases of hemophilia are not detected until profuse hemorrhage occurs from a mild injury. The bleeding may occur spontaneously.

Since hemophilia is confined to the male sex but is transmitted by the females, this patient may be told that her sons will most likely have hemophilia but her daughters will definitely not have the disease. On the other hand, her daughters will transmit the disease to their sons, who will most likely have evidences of the disease.

## URTICARIA

*To the Editor*—I have a patient who has had urticaria daily for one year. This occasionally assumes the characteristics of angioneurotic edema. The child has been on elimination diets and cutaneous skin tests have failed to reveal any allergic reaction. In addition she has been given alkalis in sufficient amounts to make the urine alkaline to litmus and subsequently was given 40 grains (2.6 Gm) of calcium chloride daily. None of these measures have improved her condition. Can you suggest additional examinations and therapy that might prove beneficial?

C A STEWART M D Minneapolis

*ANSWER*—There are several unmentioned features in the query which may prove helpful in determining the cause of the urticaria. Since intestinal parasites, particularly roundworms and tapeworms, sometimes cause urticaria, it would be advisable to make a careful study of the feces. A thorough search for focal infection should be made, although this source of urticaria is not common in children. Is there any gastro-intestinal disturbance such as constipation? The inquirer mentions the use of alkalis. Insufficient acidity of the gastric juice is a greater possibility as a cause of digestive disturbances and resultant urticaria. It may be well to try the therapeutic effect of dilute hydrochloric acid or even other digestants, such as pancreatic extract.

A possible drug allergy should be considered. It may be well also to try intracutaneous tests to various allergens in addition to the cutaneous tests mentioned. The hypodermic use of parathyroid extract (from 4 to 10 units) every day or two days for several doses has been found of value in some instances. Occasionally, the use of from 0.3 to 0.5 Gm of peptone half an hour before each meal has been beneficial. It should not be forgotten that in many cases of urticaria there is a marked nervous element to be considered.

## INFECTION WITH GONORRHEA

*To the Editor*—1 Is there such a thing as a gonococcus carrier in the male or female genito-urinary tract? 2 Can the first sign of a venereal (gonococcal) infection in the female present itself with a Bartholin gland abscess when a careful history brings forth repeated denials of any vaginal discharge whatever? 3 What is the shortest and what is the longest possible duration of the formation of a Bartholin gland abscess (gonorrheal) following a gonorrheal infection? 4 Is it possible for a man cohabiting with a woman regularly for several years to remain free from a gonorrheal infection when the female has a quiescent gonococcal infection in the Bartholin gland for a period of seven or eight years? (Here there is no clinical evidence of a gonorrheal infection either in the Bartholin gland or in the female genitalia.) 5 Is it possible that no evidence may be present (clinical or laboratory) of gonorrheal infection during a laparotomy and following a curettage done at the same stage when there is present (not determined clinically) a quiescent gonococcal infection of the Bartholin gland?

JACOB STERN M D Chicago

*ANSWER*—1 Yes, but usually associated with some symptoms.  
2 This is possible.  
3 This may vary from a number of days to many weeks.  
4 This does not seem possible unless one believes in immunity.  
5 Yes.

## DRUG EFFECTS ON CORONARY CIRCULATION

*To the Editor*—I am using a preparation containing theobromine 5 grains (0.3 Gm) and phenobarbital one fourth grain (0.016 Gm) for certain types of heart cases and with some apparent success. I usually have them given at the rate of one tablet after each of the three meals in a day. Do you think the benefits that seem to result come from the phenobarbital alone or is theobromine 5 grains three times a day an adequate dose for producing any vasodilating effects? Please omit name.

M D New York

*ANSWER*—The effect of theobromine on the coronary circulation is relatively feeble as compared with that of theophylline though it has a similar tendency. The dose of phenobarbital is relatively small to have much vasodilator effect. The combination is, however, a synergistic one and it may have some therapeutic value, as is suggested by the apparent success reported. Should it fail in cases in which this treatment seems indicated, doubling the dose of the combination would be permissible. Indeed, the dose of phenobarbital might be increased up to the point of producing drowsiness. If gastric distress or other untoward phenomena are produced by the theobromine theophylline—which is active in smaller dosage—might be tried instead.

## MECHANISM OF EXOPHTHALMOS

*To the Editor*—Please explain the mechanism of exophthalmos in exophthalmic goiter.

JOSEPH DEUTSCH M D Cleveland

*ANSWER*—Exophthalmos in exophthalmic goiter is probably due to a nervous mechanism, possibly located in the hypothalamus. The excess thyroid hormone present in the disease may activate this mechanism directly, or through its effect on the sympathetic nervous system, or through its effect on the pituitary. It has been shown that (1) thyrotropic pituitary hormone or cyanide will produce exophthalmos in thyroidectomized animals, that is procedures which cannot raise the thyroxine blood level but which probably have a pituitary and nerve stimulating action, (2) thyrotropic hormone in excess in normal animals may lead to exophthalmos in animals, and (3) thyroid feeding to cretin rabbits will produce exophthalmos, that is, that excess thyroid hormone in a pathologic animal will produce exophthalmos. The nervous impulses produce protrusion of the eye by active engorgement of the blood vessels of the orbit and by stimulating the retrobulbar musculature, and possibly by effects on the palpebral muscles.

## READS FORMULA FOR COMPUTING BASAL METABOLISM

*To the Editor*—On page 1390 of THE JOURNAL Oct 26 1935 there is an abstract of an article on Read's formula for computation of the basal metabolic rate. I wonder if it would be possible to explain this.

M D Connecticut

*ANSWER*—Basal metabolic rate = 0.75 (pulse rate plus 0.74 pulse pressure) — 72. The arithmetic can best be illustrated by the following example, in which the pulse rate is 80 per minute, the systolic blood pressure 120 mm of mercury and the diastolic 80 mm, which gives a pulse pressure of 120 — 80 = 40. In the following calculation unnecessary decimal places are dropped and both 0.75 and 0.74 are considered equal to  $\frac{3}{4}$ .

$$\begin{aligned} BMR &= 0.75 (80 + [0.74 \times 40]) - 72 \\ &= 0.75 (80 + 30) - 72 \\ &= (0.75 \times 110) - 72 \\ &= 83 - 72 \\ &= + 11 \end{aligned}$$

If the inquirer is going to use any of the Read formulas he will probably wish to use the latest modification. The arithmetic for these has been worked out in a convenient monogram by Conroe.

## FISTULA IN ANO

*To the Editor*—Is there any new treatment of fistula in ano that is worth while? Is there any real nonsurgical therapy? Is there any injection therapy of value such as has been used for hemorrhoids varices and recently for hernias? Please omit name.

M D, Iowa

*ANSWER*—Success in the treatment of fistula-in-ano depends on one's conception of its origin. The ischioanal abscess, which is usually considered the beginning of the disease, is in reality the third stage in the development of the fistula. The infection begins in the anal crypts, extends through, external to or internal to, the anal sphincters, out into the ischioanal space, where the abscess develops. Any treatment from which success may be expected must be aimed at the source of the infection.

There is no new treatment. Surgical methods are usually the only ones that can produce a cure. Claims have been made for injection of the sinuses with various medicaments, but none can be said to have proved value.

## MEASURING VISUAL ACUITY

*To the Editor*—I am anxious to be informed of the method of measuring visual acuity and expressing it percentally. Has a method been worked out whereby advice can be given to insurance companies relative to percentage of loss of vision? I have the cards which bear the recommendation of the American Medical Association. Is there anything other than these to guide me? WILLIAM J. HERTZ M D Allentown Pa.

*ANSWER*—This question is discussed in detail in the report of the Committee on Compensation for Eye Injuries that was accepted by the House of Delegates in 1925 and published at length in THE JOURNAL, July 11, 1925 p 113. The visual acuity charts published by the American Medical Association are based on that report, which has not been changed since the original publication. The questioner is advised to consult that report and if there are further questions, after study any of the members of the committee will be glad to go into detail with him on questionable points.

POSTOPERATIVE ROENTGEN THERAPY IN  
BREAST CARCINOMA

To the Editor—A woman aged 35 had a radical breast resection for an adenocarcinoma of the breast. She is now ready for postoperative roentgen therapy. It was suggested by a roentgenologist that an artificial menopause be induced because of recent observations that sterilization of the ovaries will prevent metastases and even sometimes prolong the lives of patients who have metastases. Is there any basis for this treatment? Would the artificial menopause created be difficult to hold, and how would it be treated? Please omit name.

M D New York

ANSWER—It is true that breast tissue, both normal and abnormal, is subject to stimulation by the ovarian secretions. Theoretically, cessation of ovarian activity should impede the growth of breast tumors, proof that this occurs requires further clinical evidence.

At the present time most of the good that can be obtained from roentgen therapy is by irradiation of the local tissues, including the axilla, as well as intensive high voltage therapy of the chest.

The artificial menopause, once established, is permanent. Symptoms of the menopause may be controlled by estrogenic substances.

## EFFECTS OF ZINC ON TISSUES

To the Editor—At a recent meeting of a medical association a physician friend of mine reported having treated a case of pruritus ani and vulvae by first applying a liberal application of strong solution of iodine (just once). He then gave the patient a prescription for calamine lotion to be applied locally three or four times a day. The result was enormous edema of the tissues followed by a complete desquamation with a copious watery discharge from the tissues three days later followed by some sloughing of the subcutaneous tissue. No other treatment had been used before or after this treatment. Is this a result of the chemical reaction between the iodine and the zinc in the calamine lotion?

JOHN L. MACE, M.D. Hastings, Neb

ANSWER—In concentrated form, the halides of zinc, including the zinc iodide, are caustic, and the result reported might well be due to the chemical reaction between the iodine and the zinc.

## MUCOUS COLITIS

To the Editor—A woman aged 40, with an ovarian neurosis for the past ten years has had mucous colitis and at present has spastic constipation and mucous colitis. All sources of infection have been eliminated all types of sedatives, enemas and colon flushes have been tried with only a few days relief. Autogenous vaccines have been tried with no result. There are no ulcerations and no parasites can be found. At present I am using bromides and oil enemas. Do you know of any new treatment?

CHARLES T. ATKINSON, M.D. Middletown, Ohio

ANSWER—Since there is no local cause for mucous colitis there is no specific local therapy. An attempt should be made to determine a possible general cause, such as a disturbance in the endocrine system, especially the thyroid. Hypothyroidism may be the cause of an excessive secretion of mucus in the large intestine. Hence at least one basal metabolism reading should be taken. The patient should be placed on a nonresidue diet and should also receive large doses of atropine or belladonna. The latter will also help the spastic constipation. Since in most cases the nervous system is involved, mild sedatives should be prescribed.

## STERNAL NOTCH

To the Editor—Will you please tell me what you understand by the sternal notch anatomically speaking? Is this expression in current use?

HAROLD I. KORN, M.D. New York

ANSWER—The term "sternal notch" is commonly used for the depression superior to the sternum and between the sternal heads of the sternocleidomastoid muscles. The BNA term is 'incisura jugularis' or jugular notch, probably because of the anastomosis between the anterior jugular veins in this region. The best descriptive term would be "suprasternal notch."

## FIBROID OF UTERUS IN PREGNANCY

To the Editor—A woman aged 38 pregnant has a fibroid on the anterior wall of the uterus on the lower segment just above the cervix and easily palpated in the anterior fornix. She is three months pregnant. The size of the fibroid has appeared to increase about 1 cm. in the last month. Being on the lower uterine segment it may interfere with delivery. Should anything be done now or at term? Kindly omit name.

M D New York

ANSWER—Intervention at this time is contraindicated. The patient will probably have a normal labor, despite the location of the tumor. The family should be given to understand that such tumors sometimes obstruct the birth canal and that cesarean section is occasionally necessary, as a rule, the labor is uneventful.

**Book Notices**

**Glandular Physiology and Therapy** A Symposium Prepared Under the Auspices of the Council on Pharmacy and Chemistry of the American Medical Association [Reprinted from the Journal of the American Medical Association] Fabrikoid Price \$2.50 Pp 528 Chicago American Medical Association 1935

The enormous increase in the number of scientific contributions to the knowledge of endocrinology, within recent years has made it difficult for even a worker in that field to keep pace with advance in the various phases of the subject. When one considers, moreover, that the methods of research have been constantly changing, as they have been improved and refined, and that much of the newer information has therefore been rather tentative and subject to constant reinterpretation, the real need for a periodic critical survey of the whole subject is self evident. The symposium presented in this well made volume includes the series of articles that recently appeared in THE JOURNAL under the same generic title. It constitutes a well documented review and appraisal of the present status of endocrine knowledge by twenty-four acknowledged authorities in the field. The value and importance of such a book at the present time cannot be overestimated. Since the impetus for the present advance in endocrinology has come from the physiologic laboratory rather than from the clinic it is to be expected that the articles dealing with the physiology of the endocrines should contain more real substance than the papers of a clinical nature. But for the very reason that the present status of endocrine therapy is frankly disappointing this volume is important from a clinical standpoint in that it should tend to moderate the overenthusiastic application of our present theories and thus decrease the inevitable subsequent negativistic reaction. In this regard the inclusion of a chapter on glandular products which are now commercially available to the practicing physician is a feature of the highest practical importance. Nevertheless, the reader cannot fail to be impressed with the great clinical potentialities of the subject and with the imminence of its practical application. Perhaps the most useful feature of this book is the complete subject index that is appended. The index renders the wealth of information and criticism available for ready reference. This volume should be in demand by every one interested in either the physiology or the therapy of the endocrines. In view of the rapidity of the advance in knowledge, it is to be hoped that this volume will be revised or supplemented at appropriate intervals.

**Digitalis** Von Dr med H Weese Priv Doz der Pharmakologie an der Universität Köln Monographien zur Pharmakologie und experimentellen Therapie Herausgegeben von Prof Dr Felix Haßner und Prof Dr Werner Schulemann Paper Price 26 marks Pp 296 with 73 illustrations Leipzig Georg Thieme 1936

This monograph embraces an analysis of the better pharmacologic literature of the digitalis bodies. It will be useful to the medical student, the internist, the specialist in cardiac diseases and the pharmacologist but this statement does not apply to the last chapter, for reasons which will appear. The author states that many internists have little knowledge of the phar-

macology of digitalis and that many pharmacologists know little of the important problems of digitalis therapy. This criticism is just. Many find it impossible to evaluate the extensive literature relating to these closely related fields, and Weese has rendered a service in presenting his analysis with such clarity that the internist may use the facts in the therapeutic treatment of cardiac disease.

A brief history of digitalis and strophanthus is presented, and the author states that after Withering had laid the foundations for the rational use of digitalis it was used without discernment in so many conditions that many years passed before its rational use was reestablished. The various methods employed for the standardization of digitalis are discussed at length. This is of interest to laboratory workers, but the details of standardization are of little interest to the internist because the pharmacopeial requirements insure a dependable supply of the drug. This is true also of the chemical means of identifying digitalis principles—not of the chemical constitution. The discussion of the older chemistry of the active and inactive principles of digitalis and those of a host of minor drugs will aid in understanding why so many preparations have been introduced as substitutes for digitalis during the last thirty years.

A chapter is devoted to the newer chemistry of the digitalis glucosides. Many have thought that they have isolated the essential principle, but while there has been great progress in this field it is widely believed that digitalis itself will continue for some time to hold first place in cardiac therapy, though this is not the view of the author. The chapter on the biochemistry of the digitalis glucosides, including those of related drugs, is concerned with many important questions, including absorption, behavior in the body, and elimination. Weese maintains that the saponin of the leaf irritates the stomach, though he does not state that it causes vomiting, which is of peripheral origin. He says that the seat of the emetic action remains to be determined, also that the cumulative action of therapeutic doses of digitoxin is injurious to the heart, in which it differs from that of strophanthin. It is true that excessive doses of digitoxin are injurious to the heart in animal experiments and that massive doses of saponin irritate the stomach, but it is doubtful whether such effects attend the therapeutic use of digitalis in man. The author also implies that pills of digitalis are contraindicated. It is possible to make a useless pill of digitalis, but it is well known that many cardiologists employ tablets of digitalis almost to the exclusion of other forms of digitalis.

Closely related to the questions of dosage and cumulation are those of absorption, distribution in the body, and elimination, but pharmacology has added little to our knowledge of the second and third of these.

The most important chapter is entitled Special Pharmacology. It includes more than one third of the monograph with about 450 references to the literature. The principal divisions of this chapter are on the action of digitalis on the isolated heart, the action on the vessels, the vagus action, the action on the closed circulation effects on metabolism of the normal and insufficient heart, and the action on the central nervous system and other organs exclusive of the heart. There are more than 100 subdivisions of this chapter. The chapter is concerned with technical procedures and it is not easy to review it satisfactorily in a brief space.

The last chapter deals with therapy and dosage. The author lays down certain principles and conclusions with which few will take issue and he also presents certain other conclusions which are justified but which are contrary to opinions that are held stubbornly by many without evidence. He believes that digitalis is useless in circulatory collapse of vasomotor origin and not associated with injury to the heart. This must be conceded by one who accepts the facts presented in the chapter on special pharmacology. It is hoped that this will discourage the routine use of digitalis in surgical operations, and in pneumonia and other acute infections in the absence of cardiac injury.

With much of the remainder of this chapter it is easy to disagree. Weese is a pharmacologist and the value of the monograph is due to his presentation of the pharmacology of digitalis. This part of the chapter is weak because the phar-

eologist attempts to direct the cardiologist and it is weak even though Weese leans heavily on Fraenkel (or because he does), since Fraenkel's views with reference to the routine intravenous use of strophanthin cannot be accepted. It may be trite to state that the internist must learn to utilize the facts presented by pharmacology, but the frequent disregard of that fact justifies its repetition.

The seventh chapter is merely a table of toxic actions of various drugs of this group; all other chapters are followed separately by references to the literature. The titles of papers are given in German. The total number of references, including repetitions in different chapters, exceeds 1200. There are many small tables, the illustrations include reproductions of photographs of crystalline principles, tracings and diagrams. The printing is excellent. No important typographic error was discovered.

**Röntgenology. The Borderlands of the Normal and Early Pathological in the Skiagram.** By Alban Kohler, Prof. Dr. med. Wiesbaden. Second English edition revised by the author. Translated and edited by Arthur Turnbull, M.A., B.Sc., M.B., Cloth. Price \$14. Pp. 681 with 401 illustrations. Baltimore: William Wood & Company, 1935.

The early utilization of the x-rays for diagnosis had its unfortunate as well as fortunate effects. The introduction of the physician to a new anatomy, to the visualization of structures often hardly familiar to the anatomist produced numerous errors in diagnosis. This book was first written in German in 1910 to elucidate this problem of distinction between the normal and the abnormal in borderline cases.

To any one who has visited Professor Kohler in his modest little office with its meager equipment this volume is a source of amazement and admiration. While the author has utilized to the full his keen observations, most of the tremendous mass of information which the book contains is derived from an exhaustive study of the anatomic and roentgenologic literature. There are liberal, often verbatim, citations from material on the subject of normal anatomy, anatomic variations, anomalies, borderline conditions, and abnormalities simulating the normal, as seen in the roentgenogram.

It would be unreasonable to expect that all of the innumerable normal variations that may be encountered on roentgenologic study would be recorded in one volume. Nevertheless, so many are found here in accessible form that the book has become indispensable to the practicing roentgenologist.

The first English translation by Turnbull was published in 1931. The present edition has been enlarged chiefly by the addition of a large number of reproductions of roentgenograms, most of the illustrations are instructive line drawings. There is some elaboration of the text particularly as to the gallbladder and the gastro-intestinal tract. The literature has been brought down to 1934 with many English and American references not cited heretofore.

It is unfortunate that the author has deliberately omitted consideration of the newer methods in roentgen diagnosis. The new edition contains a small section on cholecystography, but, aside from the gastro-intestinal tract, practically no discussion of the use of contrast mediums elsewhere. Even such standard procedures as bronchography and urography, both retrograde and intravenous are ignored. The material on the bones and joints is far superior to that on the internal organs.

Certain minor criticisms should be noted. The bibliography is inconsistent in form and many references are difficult to follow. Proof-reading errors are unusually common, the most irritating being the use of wrong figure numbers in the text. The terminology, owing partly to awkwardness of translation and partly to the use of old anatomic and clinical nomenclature, is occasionally confusing. Numerous statements might well be questioned, e.g., that satisfactory roentgenograms of the chest cannot be made with intensifying screens, in most instances an attempt is made to quote several opinions on moot points.

The detailed description of the two diseases bearing the author's name—those of the navicular of the foot and of the second metatarsophalangeal joint—is of unusual interest. The discussion of the merits of orthodiagraphy and teleroentgenography is illuminating.

This edition is not vitally different from the previous English edition. Either is invaluable to any physician attempting to use x-rays for diagnosis.

**Maladies des femmes enceintes I Affections du tube digestif.** Par Henri Vignes, professeur agrégé à la Faculté de médecine de Paris. Avec la collaboration de G. Lauret et P. Olivier Pallud. Papier. Price 40 francs. Pp. 317 with 34 illustrations. Paris: Masson & Cie, 1935.

**Maladies des femmes enceintes II Affections du foie, du pancréas, maladies de la nutrition, parois abdominales, péritonée.** Par Henri Vignes, professeur agrégé à la Faculté de médecine de Paris. Avec la collaboration de G. Lauret, Jean Olivier et P. Olivier Pallud. Papier. Price 25 francs. Pp. 205. Paris: Masson & Cie, 1935.

In these two volumes the author has amassed an enormous amount of information concerning illnesses that may occur during pregnancy. The first volume is devoted entirely to disorders of the intestinal tract. The twenty chapters of this volume include illnesses involving each anatomic division of the gastro-intestinal tract from the mouth to the rectum. Five chapters deal with vomiting. In the second volume the author takes up diseases of the liver, gallbladder and pancreas, and also disturbances in nutrition, abnormalities of the abdominal wall and disorders of the peritoneum. The information presented in these two volumes is encyclopedic in character. With his customary thoroughness and diligence Vignes has reviewed not only the French literature but also the American, British and German references for his facts. For each illness discussed, extensive sections on therapy are added. These books are well printed and written in an easily readable style. They should be in the library of every obstetrician and internist, for they are invaluable sources of reference.

**Formulary of the University Hospital, University of Michigan, 1934.** By Harvey A. K. Whitney, Chief Pharmacist, Ann Arbor, Michigan. Cloth. Price \$2.50. Loose Leaf. Ann Arbor: Edwards Brothers Inc. [n. d.]

This formulary is a loose-leaf booklet containing the U. S. P., N. F., N. N. R. and University of Michigan (designated U. M.) preparations in use at this hospital. The author, chief pharmacist of the hospital, recommends reference to New and Nonofficial Remedies and the Epitome of the United States Pharmacopoeia and National Formulary for evaluation of various items. The pages are not numbered but the preparations are indexed by group and stem number and entered in numerical order (Vioform is indexed 80.70, 80 refers to "Anti Amebiasis" 70 is the item number). The metric system is used exclusively and the preparations are given in prescription form with a statement of uses and directions for administration. In common with other similar formularies, it would seem to lead if not to the use of numbers at least to mechanical copying by the house officers. It contains directions for drafting a prescription and a table of equivalents. The usefulness of this book would appear to be limited to the hospital for which it was specifically designed.

**The Probability of Commitment for a Mental Disorder of Any Kind Based on the Individual's Family History.** By Serge Androp, M.D. Eugenics Research Association Monograph Series Number 5. Price Winning Research on the Genetics of Mental Disorders. Paper. Price 50 cents. Pp. 79 with 56 illustrations. Cold Spring Harbor, Long Island, N. Y. 1935.

This little volume is made up of some seventy-nine pages, of which the last fifty-seven consist of genetic charts showing families in which there have been insanity. If this piece of work is "the winning research on the genetics of mental disorders" of the Eugenics Record Office, one must be impressed by the fact that the others must have been extremely unsatisfactory. Androp gives no real statistical treatment of his material, most of the results being expressed in percentage evaluations. Criminality, epilepsy, feeble-mindedness and insanity are evaluated on an equal level in spite of the fact that it is known that criminality in a rural community represents entirely different mental traits than that in an urban community and also that the epilepsies cannot all be classified from the same standpoint. Nevertheless, certain factual material is disclosed. For instance, when both parents were mentally disordered, 69 per cent of the children were likewise mentally disordered. In the case of one parent being mentally disordered, 46 per cent of the children were mentally disordered and so on through thirteen different family relationships. Several interesting conclusions are drawn, for example, that it is unimportant to determine whether mental disorder was mendelian in behavior that mental disorders are inherited even if the mode of inher-

tance cannot be demonstrated. All in all, one is led to believe that a good deal of time is consumed in carrying out this work and in obtaining pedigrees but that the results are scarcely worth any sort of prize and only add force to general conclusions which have previously been rather universally held.

**The Cerebrospinal Fluid and Its Relation to the Blood. A Physiological and Clinical Study.** By Solomon Katzenelbogen M.D. Associate in Psychiatry in charge of the Laboratory of Internal Medicine the Henry Phipps Psychiatric Clinic the Johns Hopkins Medical School. Cloth Price \$5. Pp 468. Baltimore: Johns Hopkins Press. London: Oxford University Press. 1935.

This book limits itself to one phase of the study of cerebrospinal fluid, namely, the relation of cerebrospinal fluid to the blood. In addition to a discussion of the comparative chemical composition of cerebrospinal fluid and of blood, which constitutes the largest part of the book, the author also takes up the questions of the origin and formation of cerebrospinal fluid and the barrier between the blood and cerebrospinal fluid. At the end of each topic he gives a summary of the facts reviewed. This summary makes it easier for the reader to get a bird's eye view of the enormous amount of literature on cerebrospinal fluid. As a whole, the literature has been brought down to date. Here and there, however, the literature of the last three or four years has not been included. This is particularly true in connection with the latest work on dextrose. Although the book contains a discussion on examination of barrier function and on arsenotherapy and bismuth therapy that have some clinical application, it is not intended as a textbook for the clinician, as it does not contain any clinical methods of examination of cerebrospinal fluid or any information on cerebrospinal fluid changes in various diseases. The author says "Evidently this book is not specifically a technical laboratory guide, nor is it a textbook in the usual sense of the word, if a textbook is supposed to offer definite outlines of knowledge." The book will, however, be found very useful as a reference work to those who are interested in the relation of the blood to the cerebrospinal fluid.

**Convalescent Care in Great Britain.** By Elizabeth Creene Gardiner. Assistant Professor and Supervisor of Medical Social Work. University of Minnesota. Social Service Monographs Number 34. Cloth Price \$1.50. Pp 163. Chicago: The University of Chicago Press. 1935.

During the spring of 1931 the author sojourned in a part of England where convalescent care is highly developed. The survey covered England, Wales and Scotland. Accommodations, in the form of convalescent homes in those countries are much more highly developed than in America. The three countries surveyed had a total of 431 such institutions in 1930 the year for which statistics are given. The book is an interesting report on institutional care for convalescents in the countries covered. The author gives a mass of information about the whole subject, instead of going into certain phases intensively. Reference is made to the rather general impression that institutions for convalescent care are badly needed in the United States. As usual, no explanation is made of why such institutions have not developed in great numbers in America and why many attempts to build them have died out for lack of support. Frequent references to voluntary contributory organizations in Great Britain show that cooperation on a noncommercial basis is highly developed.

**For Stutterers.** By Smiley Blanton M.D. Assistant Professor of Clinical Psychiatry. Cornell University Medical College and Morgantown, W. Va. Blanton. With an introduction by J. Ramsay Hunt M.D. Sc.D. Professor of Neurology. Columbia University. Cloth Price \$2. Pp 191. New York & London: D. Appleton Century Company, Inc. 1936.

These authors are known for their previous works on speech difficulties and child guidance. The present book is a conglomeration of material which they have collected in their work in these two fields and combined into a book which is neither "fish, fowl nor good red meat" dealing with the problem of stuttering. One cannot cavil with the fact that the authors are qualified to write the present book and certainly this sort of book has been needed, namely one that could deal with the matter of stuttering from the standpoint of medical psychology. The statement on the jacket that this is the first book to approach the problem of stuttering from that point of

view is obviously untrue. Bluemel and others have previously published work from this standpoint, and books are already available for the student of speech correction. The present volume is too elementary for those technically trained to do speech work and leaves too much for granted for the layman or the stutterer, without other background to use. As a matter of fact, books on stuttering have aroused false hopes on the part of the sufferers and it seems likely that the present volume will be no less likely to do so. For the psychiatrist who wishes to do some speech correction, the book contains a number of excellent clues. Two chapters, for instance, are devoted to a discussion on emotional patterns in the Freudian sense. There are brief chapters on the theories of stuttering, causes of the symptom complex and brief chapters devoted to treatment. From the standpoint of practical therapeutics, the authors' vast experience cannot be ignored and can be easily perceived. Emphasis is laid on the fact that too much attention, directed toward a child's stuttering, is almost universally harmful, and of course the whole point of view that Freudian interpretations are helpful in explaining stuttering and reveal methods of treatment is one which represents the thought of many of the most experienced and competent child guidance experts at present.

### MEDICOLEGAL ABSTRACTS

**Accident Insurance. Extraction of Tooth as "Surgical Treatment."**—The defendant insurance company issued a policy to Mrs. Carroll providing certain benefits for "loss resulting directly and independently of all other causes from bodily injuries effected solely through external, violent and accidental means." The policy excluded from coverage "accident, injury, death or other loss caused directly or indirectly by medical or surgical treatment." In treating the insured for pyorrhea, a dentist extracted a tooth. Acute gangrenous cellulitis developed, from which the insured died. The beneficiary named in the policy recovered judgment against the defendant insurance company and an appeal from that judgment was eventually determined by the commission of appeals of Texas, section A.

While the extraction of the insured's tooth, and the commission of appeals constituted the accidental means whereby the death of the insured was caused and was external and violent, yet the extraction constituted "surgical treatment." Hence the death was not covered by the policy. The judgment in favor of the beneficiary was accordingly reversed and judgment given for the insurance company. The opinion of the commission of appeals was adopted by the Supreme Court—*Century Indemnity Co. v. Carroll (Texas) 86 S.W. (2d) 1083*.

**Liability for Injury to Unborn Child.**—A truck belonging to the Magnolia Coca Cola Bottling Company collided with an automobile driven by one of the defendants in error, Mrs. Jordan who was pregnant at the time. As a result of the collision, Mrs. Jordan gave premature birth to twin babies. One baby, after living nineteen days, died as a result of the injuries suffered by reason of the collision. Suit was instituted against the company and the trial court gave judgment for the injuries suffered by Mrs. Jordan but refused to render judgment for the loss of the services of the child, on the ground that "the law gives to parents no cause of action for the loss of a child which dies as a proximate result of injuries while it is still quick in the womb of its mother, even though such injuries be inflicted by the negligence of the defendant." The court of civil appeals reformed the judgment of the trial court by allowing an additional sum for the death of the child (47 S.W. (2d) 901, abstr. THE JOURNAL Feb. 4, 1933 p. 365). The company then appealed to the Supreme Court of Texas.

The Supreme Court could find no decision by an appellate court of final jurisdiction holding that damages for prenatal

injury may be recovered either by the injured child if it is born and lives or by its beneficiaries in the event of its death from such injury. The principal reasons given in the decisions for denial of recovery, the court said, are briefly stated in *Drobner v Peters* 232 N Y 220, 133 N E 567, 20 A L R 1503

Lack of authority practical inconvenience and possible injustice no separate entity apart from the mother and therefore no duty of care, no person or human being in esse at the time of the accident

The arguments which have been advanced in favor of recovery are (1) that, when the law punishes for murder one who inflicts injuries on an unborn child from which it dies after having been born alive, it should in reason give the infant which survives the right to recover damages occasioned by the same injuries, (2) that a law which protects the unborn child in inheritance and devise and other rights of property and withholds relief or redress for more serious wrongs which affect its physical well being is wanting in symmetry and denies the greater right while respecting the lesser (3) that if the unborn child reaches such stage and development that it could and would live if then born or otherwise delivered from its mother it should be regarded as a distinct being toward which the duty of exercising care exists, and (4) that on principle, and regardless of precedents, recovery should be permitted, there being a wrong and consequent injury

But, said the Supreme Court in *Texas* a person cannot be convicted of homicide of a newly born child unless it is shown that at the time the offense is alleged to have been committed the child has been completely expelled from its mother, and that after being thus born it breathed and its blood circulated independent of its mother. The decisions which protect unborn children in property and property rights, continued the court, only undertake by indulgence of a fiction of existence to save to the child property which in fairness belongs to it. They do not support the imposition of liability on others for torts indirectly committed against a prospective human being, one unseen and unknown, and who may never have an independent existence. The third argument in favor of recovery, said the court, raises the question: When does life begin? "In civil rights life begins with birth." In the law of inheritance life begins with conception." 37 C J 347. In *State v Winthrop*, 43 Iowa 519, 22 Am Rep 257, it was held that a child does not have an independent life, and so is not a human being, until the establishment of respiration and independent circulation. The arguments in the present case in favor of recovery of damages for injury to the unborn child, observed the court, go no further than to insist that a recovery should be had if the injury is suffered at a time when the child has become viable, that is, when it could live apart from its mother. They concede that up to that time the child is only a part of its mother, and that injury to it is injury to her and not to a separate entity. But how, questioned the court, is the exact time for this change of status to be determined? The birth of the child alive affords no satisfactory proof of its viability at the time of a previous injury. In a given case, resort must be had to scientific or expert testimony. How can the most expert mark a line between the viability and the nonviability of an unborn child? The law must be practical. "Neither does the medical or scientific recognition of the separate entity of an unborn child aid in determining its legal rights. The law cannot always be scientific or technically correct. It must often content itself with being merely practical."—*Utts v Milwaukee Electric R & L Co* 164 Wis 272, 159 N W 916, L R A 1917B, 334. Finally, the court said, injuries often are suffered for which no relief can be granted. The task is not to undertake in the particular case to do justice in the abstract, but to ascertain whether in accordance with sound principles of the law of torts there is liability. The existence of duty and breach of duty constitutes in the law of negligence the foundation of liability. Tested by the knowledge experience and conduct of the ordinary prudent man, the defendant, in the opinion of the court, owed no duty of care to the unborn child in the present case, apart from the duty to avoid injuring the mother.

The Supreme Court, therefore, reversed the judgment of court of civil appeals so far as it allowed damages for the death of the child—*Magnolia Coca Cola Bottling Co v Jordan (Texas)*, 78 S W (2d) 944

## Current Medical Literature

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

#### Hematomorphyrin Treatment of Depressive Psychoses

—Angus treated forty-one cases (fourteen manic depressive of the depressed type, one manic-depressive mixed, eleven involutional melancholia, nine schizophrenic, three psychoneurotic and three miscellaneous with some organic factors) with hematomorphyrin, with laboratory controls. All the cases were under hospital care, by far the majority were of long standing, and many had had previous courses of treatment of various types without any improvement. Six of the manic depressive patients, one schizophrenic and one psychoneurotic recovered or were much improved, of the remainder ten were improved, five showed slight improvement and eighteen were unaffected. The blood calcium level and the blood sugar level fell in all the cases, though to a more marked degree in the improved group. The sugar tolerance curves fell in the improved group and to a less degree in some of the unimproved cases though it remained constant or even rose in some of the latter. The improved cases showed a slight loss of weight or at most a very slight gain, while the weight in general definitely increased in the unimproved cases. The basal metabolic rate increased slightly in the improved cases but was within normal limits in the majority of all cases. The nonprotein nitrogen increased slightly in the unimproved patients but fell correspondingly little in the recovered or improved patients. There was a

general tendency in all cases to a decreased white blood count. In the improved patients the red blood count increased, while it fell in the group that remained stationary, the hemoglobin value was unchanged in the former and fell in the latter.

**Visualization of Cerebral Vessels**—Loman and Myerson have developed a method by which colloidal thorium dioxide (thorotrast) may be injected directly into the carotid artery. They have performed several hundred punctures of this vessel with little more difficulty than in entering the brachial artery. In injecting substances such as colloidal thorium dioxide, complete assurance that the needle is well within the lumen of the vessel is necessary. The best position for puncture of the carotid artery is the supine, with the head hyperextended. The side of the neck is sterilized and the skin and subcutaneous tissues at the level of the cricoid cartilage are infiltrated with procaine hydrochloride. It is well to make the puncture so that the needle enters the vessel well below the bifurcation of the common carotid artery, at the level of the cricoid cartilage. Otherwise the needle may enter the external carotid and the thorium dioxide will fail to visualize the cerebral vessels. With the fingers placed as a guide over the line of maximal impact of the artery the common carotid is punctured by a 1½ inch, number 18 or 19 gage needle, connected by means of a three-way stopcock to a 20 cc syringe. The stopcock is in turn connected to a glass tube and stiff rubber tubing both of which are filled with citrate solution, and finally to an aneroid Tyco's manometer. In puncturing the artery the direction of the needle should be as nearly parallel to the skin as possible. Once the blood enters the syringe the barrel of which is forced up by the pressure of the blood the stopcock is turned so that the carotid pressure becomes registered on the manometer. If the needle is well within the lumen of the artery, there are free and wide oscillations of the manometric needle and furthermore, compression of the carotid below the site of puncture causes a steady fall in pressure and an immediate return to normal pressure and wide oscillations following the release of the compression. Only if these two conditions obtain is the syringe disconnected and replaced by one containing the colloidal thorium dioxide. Sufficient concentration of the medium within the cerebral vessels for good roentgenographic visualization may be accomplished by compressing the homolateral carotid at the root of the neck, preventing by this means the injected substance from flowing through the cerebral vessels at too rapid a rate, or the outflow of blood from the cranial cavity may be slowed down by strongly compressing both internal jugular veins over the sternomastoid muscles. While either method of compression is being continued the medium is injected as rapidly as possible. If the needle is well within

the lumen of the artery, little resistance to the injection is encountered. Jugular compression appears to be superior to that of carotid compression because there is much less discomfort to the patient, and not only are as good arteriograms obtained but the results indicate that better phlebograms are obtained. The roentgenographic technic used was as follows: tube distance 60 inches, 80 kilovolts (peak), 50 milliamperes, exposure half a second. Lateral views of the skull were taken. Excellent arteriograms were consistently obtained by making the first exposure immediately at the completion of the injection of 10 cc of colloidal thorium dioxide. In one instance, 5 cc of the medium outlined the cerebral arteries although with not as great a contrast as with 10 cc. A fair phlebogram may be made from three to four seconds after the first film is taken.

**Giant Rugae Resembling Carcinoma**—Kantor reports two cases illustrating the difficulty of diagnosis in the presence of marked hypertrophic gastritis (giant rugae). At first the roentgenogram would seem to be misleading, particularly because the modern method of mucosal visualization is better equipped to reveal suggestive filling defects than is the original full barium sulfate meal procedure. It is just this type of service—the early demonstration of small filling defects, before the appearance of “characteristic signs and symptoms” of neoplasm—that is one of the chief contributions of roentgen diagnosis. Hypertrophic gastritis is just as real a clinical and pathologic entity as are the other organic lesions that have recently been dominating attention. One must learn to recognize the roentgen appearance of giant rugae—hence the desirability of publishing roentgenograms of proved cases and trying to differentiate them, if possible, from filling defects due to carcinoma. If such a decision cannot be made from a single observation, one must employ the principle of repeated reexaminations at frequent intervals, with rigid observation of the clinical course of the patient during the interval of watchful waiting. Even so exploratory operation will be unavoidable in some cases. Both cited cases showed resemblance to carcinoma and yet were proved benign at operation.

Tuberculosis Survey in Papago Indian Area of Southern Arizona E. R. Long and H. W. Hetherington Philadelphia—p. 407

**Tuberculomas of Central Nervous System**—In 7,000 consecutive necropsies Jaffe and Schultz encountered forty-nine cases of tuberculoma of the central nervous system in forty-eight of which the brain and in one of which the spinal cord was the site of the lesions. Among these 7,000 necropsies there were 1,039 cases of active tuberculosis in 771 of which the tuberculosis was the main disease. The forty-nine cases were divided into two groups: one group in which the lesions of the central nervous system were associated with a generalizing tuberculosis and one group in which only isolated hematogenic foci were found. In the latter group there were several cases in which the tuberculomas of the central nervous system were the only active tuberculous foci. In the generalizing form of tuberculosis an early and a late type were distinguished. The early generalization is directly connected with the primary lesion while the late generalization is due either to the exacerbation of a temporarily quiescent lesion in a lymph node or to

a progressive isolated tuberculosis of the lungs or any other organ. The average age is lowest in the group of early generalization. In generalizing tuberculosis multiplicity of tuberculomas is more common than in the nongeneralizing form. In generalizing tuberculosis 50 per cent of the tuberculomas were multiple, while in the nongeneralizing tuberculosis only 29 per cent of the tuberculomas were multiple. In the generalizing tuberculosis the incidence of meningitis was 6 per cent and in the nongeneralizing tuberculosis it was 61 per cent.

**Anthropometric Study of Tuberculous Children**—Pryor and Mathiasen declare that in their present study the tuberculous children (107 boys and 103 girls) represent a highly selected group characterized by definitely diagnosed pathologic changes in the chest. They were resident in several sanatoriums and in private homes. All had positive tuberculin skin reactions and, in addition, either positive sputum, positive stomach washings or positive pathologic processes demonstrated in their chest plates. The control group represents 6,000 healthy children of the same age distribution, from the same geographic region, of the same racial stocks and, as nearly possible a random sample of the general population. The 176 tuberculous children who were seen in the various county sanatoriums probably came from the lower social economic groups, and the thirty-four in private practice probably came from the upper level. Examination of their data failed to find the so-called flat chest of tuberculosis. In this series tuberculous girls had deeper chests than the normal population, since the mean anteroposterior diameters were larger than the means of the normal population. The mean anteroposterior diameters for the tuberculous boys tended to be greater than the means for the control group until adolescence when the normal group became greater. Lateral thoracic mean diameters of the tuberculous children, both boys and girls, were less than the means of the normal population. The preadolescent tuberculous children tended to have barrel-shaped chests compared to the normal population, since they were both narrower and deeper than the controls. Mean bi-iliac diameters were the same or smaller for the tuberculous groups compared with the normal population for both sexes. The width-length indexes had consistently smaller mean values at all ages and for both sexes in the tuberculous group than in the normal control group. The authors believe that the tuberculous children therefore represented the linear type of build with smaller bones and were more delicately made than average children of the normal population. Head breadths, face measurements and necks tended to be smaller for the tuberculous children. There were very small deviations in height, the means for the tuberculous children alternating above and below the means for the normal population for both boys and girls. The tuberculous children were quite consistently below the controls in weight, but when their slender body builds were taken into consideration their relative nutrition was just as good.

Granulocytic Angina: Report of Three Cases with Two Fatalities I. Frank Chicago—p. 310

Nasofrontal Connections: Study Based on One Hundred Consecutive Dissections K. A. Kasper Philadelphia—p. 322

**Rhinoscleroma**—Chamberlin encountered two patients with rhinoscleroma in thirty years of clinical work. Neither was a native born American, although in the second case, owing to the patient's long sojourn in this country (twenty six years), there might be more than a suspicion that the disease was indigenous. He was of more than average intelligence and could not remember having been in contact with any person with a similar disease either in Russia or since his arrival in this country. Cases in native-born Americans have been reported by Wende, Watkins, Wood, Figg, Canfield, and Helwig and Jaime Hajek has suggested that the recent recognition

of scleroma throughout practically the entire civilized world may be due not necessarily to its wider distribution but rather to an increased acquaintance with the disease, previous cases having escaped unnoticed. Scleroma, or rhinoscleroma is no longer confined to a fairly definite locality in southeastern Europe but is fairly well distributed over the entire world. The bacillus of Frisch is easily obtained in all cases in practically pure culture. This bacillus is very similar to the bacillus of Friedländer and of Abel. Although typical local lesions can be produced by injecting it into animals, it fails to satisfy the postulates of Koch, in that the disease itself cannot be reproduced in animals or in man. The culture of the bacillus of Frisch is not necessary for the absolute diagnosis of the disease. Necessary, however, is the presence of the vacuolated lace or foam cells of Mikulicz and the hyaline bodies of Unna. The mode of transmission or contagion is still unknown. Roentgen radiation or radium in proper dosage offers the best hope of control or cure.

A Review of Urologic Surgery A J Scholl Los Angeles E S Judd Rochester Minn J Verbrugge Antwerp Belgium A B Hepler Seattle R Gutierrez New York and V J O'Connor Chicago—p 544

**Osteomyelitis of Infants**—Green and Shannon discuss ninety-five cases of osteomyelitis in children less than 2 years of age. Streptococcal osteomyelitis occurs twice as frequently as staphylococcal osteomyelitis in infants. Antecedent infections were present in 55 per cent of the cases. When associated with infection of the respiratory tract osteomyelitis was due usually to *Streptococcus haemolyticus*, occasionally to the pneumococcus and rarely to *Staphylococcus aureus*. When associated with cutaneous lesions the organism was more likely to be *Staphylococcus aureus*. There was a history of mild trauma in 17 per cent of the cases. A diagnosis is made later in the course of the disease in infants than in older persons. Differential diagnosis demands the particular consideration of sepsis of the joints, infection of the soft tissues and scurvy with infection elsewhere. It is suggested that the differences between the osteomyelitic syndrome of infants and that of older children are largely dependent on three factors. 1 The streptococcus is observed more frequently in infants than in older children. 2 The anatomic construction of the bone in infants, characterized by larger cancellous spaces in the bone allows the infection to pass more readily from its site of origin the metaphysis, to the subperiosteal space, the periosteum is more loosely attached in the infant and allows the decompression to occur the periosteum then ruptures allowing the pus to escape into the soft tissues, without sequestration except in rare instances. 3 The absorption of dead bone occurs more rapidly in infants, as does the formation of new bone. Surgical intervention at an early period in the disease is not essential. If the condition of the patient is satisfactory and the lesion can be located definitely before operation an operation may be performed. If surgical intervention is contraindicated by the general condition of the patient, the part should be immobilized and supportive treatment should be given. If an operation is performed on the bone it should not be extensive. Adequate drainage of the fluctuant abscess in infants without operation on the bone seems to give as satisfactory results as a more extensive procedure. If the abscess is drained a prolonged search for the lesion in the bone should never be made. Pack-

ing the wound open with petrolatum gauze combined with immobilization in a plaster cast is a desirable method of treatment. The cast should be bivalved to allow for dressings. The first dressing should not be made until ten days after the operation, thus allowing granulation tissue to line the wound, and at weekly intervals thereafter with replacement of the petrolatum. The part should be immobilized until the wound has healed and there is evidence of healing in the roentgenogram.

**Injection of Eosin into Knee Joint**—Burman believes that from a practical standpoint it may be stated (even from his series of nine cases) that eosin can cause diffuse staining of normal cartilage and synovia and that, while erosions of various etiology on cartilage will stain selectively with eosin normal cartilage in the presence of these erosions will also stain usually in spots. The visualization of an eroded area is made clearer by the use of the dye. Lightly altered cartilage without erosion usually does not stain. Greatly degenerated cartilage stains diffusely. Since the dye is nonirritating and since it clarifies vision, he sees no reason why it should not be used in properly selected cases as an adjunct to arthroscopy.

**Experimental Arsphenamine Dermatitis**—The experiments of Cormia revealed that two lots of one brand and one of another brand of neoarsphenamine varied greatly in their power to cause cutaneous sensitization of normal guinea-pigs fed on a diet high in vitamin C. The sensitizing power of one of these arsphenamines seemed to coincide roughly with that developed in a patient who had been inadvertently given a paravenous injection of the same lot of arsphenamine. A higher degree of cutaneous hypersensitivity was developed when a single lot of an arsphenamine of a high sensitizing index was used throughout the sensitizing period. The patch test was of no value in the detection of cutaneous hypersensitivity to neoarsphenamine in guinea-pigs. Cutaneous sensitivity to the arsenicals, as developed and determined by the intradermal method is apparently confined to the trivalent group. Intravenous testing may be a more accurate method of determining cutaneous sensitivity to the arsphenamines. Cutaneous arsphenamine hypersensitivity in guinea-pigs differs in its nature from that seen in man. The second intradermal injection apparently not essential for the development of arsphenamine dermatitis in man is a necessary prerequisite for the development of cutaneous sensitivity in guinea-pigs. The localized nature of the reactivity in guinea-pigs suggests that a disturbance in the local cellular equilibrium had been caused by the direct action of the arsphenamine solution. That this may be due in part to local tissue injury is inferred from the fact that vascularly

conferred arsphenamine gives rise to a cutaneous flare only when the initial injury has been followed by local cutaneous assault

**Use of Strophanthin in Treatment of Auricular Fibrillation**—Rikert and Hepburn gave uniform intravenous doses of  $\frac{1}{400}$  grain (0.00065 Gm) of strophanthin more than 200 times to thirty-three patients, of whom twenty-nine had auricular fibrillation. One patient developed ventricular fibrillation and died twenty minutes after receiving strophanthin, but she was unconscious and moribund at the time strophanthin was given and had recently been taking digitalis. Vomiting occurred in four patients, two of whom were vomiting before the drug was used. The results agree with those of Wyckoff and Goldring in that (1) a large dose of strophanthin is safe intravenously if digitalis has not been administered recently (2) febrile patients require larger doses (3) a definite reduction in heart rate is usually obtained in from five to fifteen minutes, reaching a maximum in from twenty to sixty minutes and (4) vomiting is rare. This dose of strophanthin can be repeated with safety in an hour if necessary, but the authors suggest that it should not be repeated until the rate has reached a stationary level or has started to increase. They therefore recommend strophanthin as a convenient, effective, cheap and safe drug for intravenous use when rapid reduction of the heart rate is desired (especially in cases of auricular fibrillation) or when vomiting or marked passive congestion renders the use of the alimentary route impossible or doubtful.

**Excessive Perspiration**—Pirie relates that in 1909 a patient who had received a prolonged course of roentgen treatment for a tuberculous hip joint told him that he did not perspire where the x-rays had fallen and perspired freely over the rest of his body. In the beginning of 1911 each of four patients with excessive perspiration received one epilation roentgen dose once a month for six months. After the sixth treatment every one was quite cured. Since that time the author has treated twenty cases of perspiration of the hands, eighteen of the feet, eighteen of the axillae and one of the face. At the end of 1935 he was able to follow up fifteen cases and ascertain that every one of them had remained cured. Larger doses less frequently or small doses more frequently have been found to be without benefit. The more excessive the perspiration, the more sure is the cure. By the word "cure" is meant either a bone-dry result or a condition of normal perspiration. No general bad effects have been reported from stopping this local perspiration, the only possible objectionable local effect is that in some cases slight telangiectasis follows. This, however, is rare. In treating the axillae the hair comes out and remains out permanently. In some cases it is thinned out and remains permanently sparse. The danger of producing telangiectasis has made the author refuse to treat another case of perspiration of the face. The fact that sweat glands can be completely destroyed in six months without injuring the skin gives one a hint for the treatment of carcinoma. The gland cells are overactive, just as the carcinoma cells are overactive. It is the overactive cell which is more sensitive to x-rays, but its degree of sensitivity is only slightly greater than that of the surrounding cells. In order to give the exact dose that will kill the overactive cell and leave the normal cell unharmed the best method is to extend the roentgen treatment over a long period as described for the treatment of excessive perspiration. The method of treatment is as follows: 90 kilowatts, 8 milliamperes distance 17 inches, no filter, one epilation dose. The author found this epilation dose equal to 250 roentgens. In treating the hands, care is taken to reduce the treatment if necessary so as not to destroy perspiration completely.

**Narcosustained Therapy in Psychosis with Heart Lesions**—Magnus encountered a few instances of psychosis associated with cardiac involvements which proved sufficiently provocative to justify the cardiologist's attention. Generally there is no definite relation between the psychotic picture and the nature of the cardiac disturbances, including even pathologic changes that may have occasioned atrophies of the brain. However, in failure of compensation the person has transient confusional states with hallucinations, especially of sight and sometimes of touch. He becomes restless with predominating elements of fear, less frequently of pleasure. Noteworthy is the variable daily state of consciousness. In mitral stenosis one is apt to encounter evidence of impairment of memory, while in precordial distress marked anxiety states seem to be more or less constant. There are some among the frankly manic depressive types (incorrectly designated as symptomatic psychosis) in whom a disturbance of the heart function may be consequential instead. Care is to be exercised in applying sleep therapy in cardiac conditions before its value and margin of safety are ascertained. The most important complications to guard against are bronchopneumonia, collapse and drug idiosyncrasies. Of lesser importance are dehydration, urinary retention, trauma and gaseous abdominal distentions. Kidney conditions, acute or chronic, are contraindications of this treatment. Sustained narcosis was seen to be distinctly beneficial in nearly all instances of cardiac disorders encountered in cases of psychosis. The author recommends this form of therapy for use in cardiologic service in cases in which every other measure previously tried has failed.

**Secretion of Gastric Mucin in Peptic Ulcer**—Anderson and Fogelson assert that the quantitative measurements of gastric mucin in ulcer patients with active lesions have shown that there is a relative mucin deficiency per cubic centimeter of gastric contents in response to an alcohol test meal. This is in agreement with the hypothesis of Hurst based on qualitative observations that there exists in the ulcer patient with an active duodenal lesion a hypoprotection as a result of a relative mucin deficiency. Quantitative evidence is also supplied that such a deficiency of mucin with its attendant hypoprotection may be corrected by feeding these patients gastric mucin and thus establishing a normal relationship between the acid and mucin components of their gastric content.

**Serum Lipids in Malnutrition**—Man and Gildea consider the role which malnutrition in itself may play in determining the amount of blood lipids. They analyzed serum for lipids in thirty one emaciated patients in six patients with weight loss without emaciation and in ten subjects who have been studied during changes in the nutritional state. In the ten malnourished patients who were followed for some time the cholesterol varied with the state of nutrition. Cholesterol was below normal in twenty six of the emaciated patients and was within normal limits in five of the six nonemaciated patients. Although the initial cholesterol varied throughout a wide range improvement in nutrition was accompanied by an increase even when the first observations were not below the normal range. The fatty acids were below normal in sixteen normal in thirteen

and above normal in two of the thirty-one patients, were only below normal in one of the six patients with weight loss and varied with nutrition in five of the ten subjects studied for some time. Concentrations of lipid phosphorus were proportional to those of cholesterol. The hypocholesterolemia could not be related to the various diseases of the patients, to tuberculosis, to increased body temperature and white blood cell count to the age of the subject or to the outcome of the disease. When there was hypocholesterolemia there were usually low values for protein and albumin. The reduction in these three substances was directly related to the state of malnutrition and previous inadequate food intake of the patients.

**Meningitis Caused by Filtrable Virus**—Scott and Rivers describe the clinical picture presented by two patients who were suffering from a nonbacterial lymphocytic meningitis, and the method by which a virus-like agent was isolated from each patient's spinal fluid. The two agents were immunologically identical and they were etiologically related to the disease process in the individuals from whom they were obtained. Experiments in support of the viral nature of the agent are presented. Details concerning the range of susceptible hosts and the clinical and pathologic picture developed in each is given. The active agent is compared with known viruses that spontaneously affect the central nervous system of man or lower animals or that might have contaminated the authors' materials because of their proximity in the laboratory. The relative importance of their agent as a cause of disease in human beings is discussed.

**Urinary Excretion of Silica in Nonsilicotic Subjects**—Goldwater determined the variations in urinary silica excretion in persons who had never been exposed to unusual amounts of silica dust. The method of King and Dolan was used for determining urinary silica. The study was divided into two parts: the first involving variations in specific gravity and the second involving urinary silica excretion in twenty-four hours in persons receiving known diets. For the specific gravity studies normal young physicians were used as subjects. For the studies involving silica output the subjects were convalescent patients in the wards of the Third Medical Division of Bellevue Hospital. In addition to the urinary studies a number of blood silica determinations were made. Variations in urinary

specific gravity were produced by having the subject drink varying amounts of water. The diet given to the subjects whose silica excretion in twenty-four hours was studied was relatively rich in fruit and green vegetables. The results show that urines having high specific gravities present a relatively high concentration of silica, and conversely. Furthermore, the urinary silica concentration in the same individual may show extreme variations within the space of two hours. The blood silica levels remained fairly constant during these experiments. The results of silica determinations made on twenty-four hour specimens of urine of five individuals receiving similar diets show that great fluctuations in both silica concentration and silica output may occur even under these conditions.

**Excretion of Vitamin C**—Hawley and her associates studied the effect of variations in the daily intake of vitamin C on the urinary excretion of cevitamic acid in twelve normal young adults. The urinary excretion of vitamin C by individuals on an average normal diet varied between 15 and 28 mg in twenty-four hours. Excretion continued at a steady rate during a preliminary control period of low vitamin C intake. Considerable individual variation was observed in the urinary response to repeated test doses of orange juice, both during and after apparent saturation with vitamin C. Comparable amounts of vitamin C given orally as orange juice and as cevitamic acid resulted in similar urinary excretion curves. Cevitamic acid administered intravenously was excreted more rapidly and more completely than when given by mouth. Variations in the intake of vitamin C had no demonstrable effect on the cevitamic acid content of whole blood or on the capillary fragility.

**Infantile Hypoglycemia**—During the last year Neff had the opportunity of seeing two unconscious infants who illustrate the importance of keeping in mind the existence of two somewhat similar clinical conditions with opposite blood chemical and metabolic significance. The impression is growing that diabetes in the first year is not so infrequent as the literature suggests. It is also becoming recognized that the opposite state of hypoglycemia occurs as a clinical entity which until recently

has been overlooked. The picture is not well known, it has no simple laboratory tests to reveal it, nor are blood sugar determinations run in a routine manner, as is the present practice in diabetes. The first important procedure in the clinical study of these conditions is the prompt examination of the urine. Even though the urine is sugar free, one should proceed to determine the percentage of sugar in the blood, as its knowledge may be of the greatest help, some cases of diabetes have intervals when there is a so-called high renal threshold for dextrose, the sugar not appearing in the urine until the glycemia is much above the customary level. A diabetic child in the author's hospital recently showed no sugar in the urine with the concentration in the blood of 197, 189 and 231 mg respectively, but at 363 mg the urine contained about 5 per cent. Blood sugar determination in nondiabetic coma and convulsions may reveal a state of hypoglycemia as the cause.

**Hypoglycosuria in Cretinism**—Costello reports a case of hypoglycemia with cretinism in a child who was first seen at the age of 4 months, weighed 22 pounds (10 Kg) and presented a clinical picture of cretinism. One-fourth grain (0.016 Gm) of thyroid was given three times a day and signs of improvement were seen immediately. At the age of 9 months he was taking 1 grain (0.065 Gm) three times a day, weighed 19½ pounds (8.8 Kg) and was able to sit up when assisted. At 14 months he could sit up alone, weighed 21 pounds (9.5 Kg) and was getting 1½ grains (0.1 Gm) three times daily. When he weighed 22½ pounds (10.2 Kg) at the age of 22 months, he was beginning to walk. At this time, however his parents discontinued therapy and for eight years the patient was treated by a chiropractor. He gradually grew worse and returned to the author at the age of 10 years. He was then 46½ inches (117 cm) tall and weighed 52 pounds (23.6 Kg). His mental ability was that of a 7 or 8 months old child, he was able to walk but could not talk. General convulsions resembling epilepsy were frequent and lasted for from two to five minutes. Defecation was possible only after enemas. His complexion was pasty and on his fingertips was a peculiar nicotine-like stain which could not be removed with ordinary solvents. According to past history, this had been present for the last two years. The teeth showed early decay and the hair was thin and dry. There was a general pseudo edema over the entire body, the lips and tongue were thick and the muscles of the extremities resembled muscular dystrophy. The liver and spleen were palpable, the genitalia well developed and reflexes sluggish. The blood creatinine was insufficient for determination and the blood sugar was 40. August 9, one-half gram (0.032 Gm) of thyroid was given three times daily and 5 ounces (140 Gm) of sugar was put in the daily diet with the hope of increasing the blood sugar content. The addition of

sugar does not necessarily raise the blood sugar, but it does fill the glycogen depots of the body. Apparently, his pancreas was overfunctioning owing to the lack of the antagonistic effect of the thyroid. August 23 the creatinine was 0.7 mg and the sugar 53.9. Thyroid was increased to 1 grain three times daily and on August 30 the creatinine was 1.3 and sugar 65.8, the weight was 52½ pounds (23.8 Kg). For the first time in three years he had a normal bowel movement and his convulsions were less frequent. September 27 the creatinine was normal and the sugar 50, his convulsions had disappeared and he was attempting to speak for the first time. His facial expression had undergone a marked change, he obeyed commands, took a keener interest in his surroundings and was changed in every respect.

Treatment of Moles and Verrucae Trichloroacetic Acid as an Analgesic Agent R R M McLaughlin New York—p 347

**Treatment of Moles and Verrucae**—McLaughlin states that a cursory review of the literature fails to show that trichloroacetic acid or the newer dichloroacetic acid has been used as an analgesic for subsequent desiccation with the Oudin current in the removal of nonmalignant moles and verrucae of the face. The method which he uses is as follows: If there is much hyperkeratosis, the surface of the lesion is shaved down. The acid is then applied full strength to the surface of the lesion with a suitable applicator. Any bleeding that may occur following shaving will be controlled by the action of the acid. After a minute or two when the painted area becomes thoroughly whitened it will be found that a degree of analgesia has developed which, in most instances is sufficient to permit light interrupted desiccation. This light desiccation will increase the analgesic effect until a moderately strong current may be used without discomfort. A slight burning from the acid and a sensation of warmth from the desiccation will usually be the only subjective sensations. The desiccation is continued until the surface of the lesion appears to be level with or slightly below the surrounding normal skin. There is a shrinking effect, which exaggerates the amount of destruction that actually occurs. If the desiccation is carried to the point at which the surface of the lesion appears to be level with the skin it will be found that complete destruction of the lesion has not been accomplished and more treatment is needed. It is often advisable to do this since the final result from fractional destruction of soft moles and fibromas may be no visible scar. The interval between treatments should be two or three weeks so that epithelization is completed before further treatment is given. After each treatment a crust forms within a few days. This should be protected and allowed to drop off. In any event the final scar will usually be smooth and soft. The method is

suitable for almost any lesion requiring desiccation: vascular nevi, scar cicatrices, keratoses and even small "corns." It is possible to curet the lesion after treatment, but a reapplication of the acid is necessary before further desiccation is done.

**Ova Associated with Hemorrhage in Basal Ganglions**—In the course of their studies on heterophyidiasis Africa and his associates encountered ova in what appeared to be old sites of capillary hemorrhages in the neighborhood of a large clot in the right basal ganglions of the brain in a case in which death was determined to be due to cerebral hemorrhage, and, in the same patient, adult *Monorchotrema taihoku* and *Heterophyes brevicaca* were recovered from the small intestine. The sections in which the eggs were found were taken from the posterodorsal wall of a large clot with irregular edges, measuring about 7 by 5 cm located in the lower limb of the internal capsule. So far as the authors are aware this is the first time that such eggs have been found in the brain.

Roentgen Diagnosis of Malignant Tumors of Stomach H Hauser and G T Pack New York—p 221

**Nasopalatine Duct Cysts**—Goodman declares that the roentgenologist should consider the possibility of the presence of a nasopalatine duct cyst whenever he observes an area of decalcification in the region of the incisor foramen. He should not rely on the routine lingual study of the upper incisor teeth in such cases but make special occlusive and stereoscopic examinations to diagnose the case properly and also to determine the relationship of the apexes of the adjacent incisor teeth to the cystic area. The error of diagnosing a small cyst as an enlarged incisor foramen should be avoided when in doubt, subsequent follow-up roentgenographic studies may show enlargement of the area of decalcification and prove it to be a cyst. Nasopalatine duct cysts are not as rare as formerly thought, and it is advisable to interpret cystic areas in the region of the incisor foramen which have no connection with the apexes of the incisor teeth as nasopalatine duct cysts. However, in cases in which these cysts have enlarged to such an extent as to encroach on these apexes, the differential diagnosis between such cysts and root or dentigerous cysts may not be possible from the roentgenograms alone, the history of the case may be of some aid if repeated swelling in the region of the palatine papilla had occurred. A thorough roentgenographic study of cases presenting an area of decalcification in the region of the incisor foramen will aid the oral surgeon. It will also often prevent the extraction of vital and normal incisor teeth by the dental surgeon as the result of erroneous interpretation of root abscess in the routine lingual study.

**Benign Prepyloric Ulcer**—In order to determine the relative and actual frequency of benign and malignant ulceration in the prepyloric portion of the stomach, Singleton has reviewed

the roentgenograms of all cases in which a diagnosis of gastric ulcer was made in the department of radiology of the Toronto General Hospital since January 1932. The prepyloric segment has been limited for the present study to include only the terminal inch (2.5 cm) of the stomach. The records show 145 cases of benign gastric ulcer, of which fifteen involved the prepyloric segment and 130 were above this region, on or near the lesser curvature. Of the fifteen patients with ulcer in the prepyloric segment seven had partial gastrectomy, and microscopically, their lesions were found to be benign gastric ulcers within 1 inch of the sphincter in each case. Each of the eight cases in which resection was not performed presented a clinical history quite compatible with ulcer roentgenologically; each showed a well defined prepyloric crater and in each case relief of symptoms and disappearance of the crater followed medical treatment. Clinically these patients have remained well and have given negative roentgen appearances over periods varying from a few months to three years. To provide a comparison, the cases in the corresponding period of time presenting the roentgen evidences of gastric cancer were reviewed with regard to the incidence of carcinoma in the pyloric end of the stomach and as to the number that involved only the small prepyloric segment. This series comprised 133 cases of gastric cancer, of which sixty involved the cardiac end or the pars media and seventy-three the pyloric end of the stomach. Of the seventy-three cases of carcinoma of the pyloric end thirteen involved only the small prepyloric segment of the stomach. These thirteen cases include four malignant prepyloric ulcers. If both series of cases showing evidence of ulcer within 1 inch of the proximal border of the sphincter are considered it is observed that fifteen of nineteen cases are benign if clinical and roentgen evidence alone is accepted. Of eleven cases in which microscopic examination of the lesion was obtained seven were found to be benign as compared to four with carcinomas. As to the accuracy of roentgen interpretation in the seven cases of benign prepyloric ulcer operated on in four the preoperative diagnosis was benign ulcer while in the other three cases the author felt that probably the lesion was benign ulcer but because of insufficient response to medical treatment and the quoted high incidence of malignant degeneration in prepyloric ulcers he felt that he could not exclude carcinomatous ulcer. In three of the four cases classified as malignant prepyloric ulcer the preoperative roentgen diagnosis was gastric cancer. The fourth case was diagnosed benign and, microscopically, showed carcinoma developing in a benign chronic ulcer.

**Risk to the Infant in Breech Delivery.**—Goethals presents a review of 1,242 breech deliveries in the Boston Living-in Hospital during a period of twenty years. The gross combined fetal (stillbirth) and neonatal death rate was 25.7 per cent. In 272 deliveries either the pregnancy was pathologic with such complications as preeclamptic toxemia, eclampsia, nephritis, syphilis, diabetes and hydramnios or labor was complicated by such conditions as placenta praevia, ablatio placentae or prolapse of the cord. Since the crude mortality in this group was 51.8 per cent the effect of pathologic pregnancy and labor as an impor-

tant factor in the high gross mortality is evident. In the 940 deliveries uncomplicated by pathologic pregnancy or labor the crude mortality was 18.5 per cent. Prematurity of the infant was common in both groups and contributed in no small measure to the crude mortality in each. Uncomplicated deliveries produced premature infants in 15.7 per cent of the cases, with a crude mortality rate of 62.1 per cent, pathologic pregnancies and labors resulted in the birth of 43.3 per cent of premature infants, with a crude mortality rate of 82.2 per cent. The risk of breech delivery alone should be computed only from cases in which uncomplicated labor occurs. This series shows the incidence of placenta praevia, ablatio placentae and prolapse of the cord to be respectively three, five and five times as frequently associated with breech presentation as with all types of delivery. In uncomplicated breech delivery the crude mortality resulting from primiparous single pregnancy was 18.1 per cent, from multiparous single, 17.2 per cent, from primiparous multiple, 24.3 per cent, and from multiparous multiple 23.8 per cent. In correcting the crude mortality figures in this series the only cases excluded are those resulting in the birth of macerated infants and grossly malformed babies. Using this standard for uncomplicated breech delivery, the corrected mortality was 13.6 per cent among 916 new-born infants, subdivided as follows: 53.6 per cent for premature, 10 per cent for immature and 6.9 per cent for mature infants. The mortality figure of 6.9 per cent, therefore, represents the risk to the living undeformed, full term infant in utero who is destined to be born by pelvic breech delivery in the absence of pathologic pregnancy on the part of the mother, and of hemorrhagic and other accidents of labor due to abnormalities of the placenta or of the umbilical cord.

**Relation of Chronic Mastitis to Certain Hormones.**—Taylor concludes that a certain minimal activity of the ovary is necessary for the development of chronic mastitis but that no relation to specific hyperfunction or hypofunction of the ovary is at present demonstrable. Exceptions and reservations must be made. In one small group of cases in which swelling of the breast sometimes with secretion, develops in the presence of a persistent follicle or corpus luteum cyst excessive secretion of estrogen is probable, but the clinical aspects of this condition are different from those of the common type of chronic mastitis with painful outer quadrant induration. It is not unlikely that an etiologic relation of other pathologic reactions of the breast to endocrine dysfunction may exist. Even for the common type of mastitis, however, it must be conceded that the present method of study has not exhausted the possibilities of such a cause. Present technical methods for the clinical determinations of estrogen and gonadotropin are far from perfect and no satisfactory test exists for the quantitative study of progestin in body fluids. A slight disturbance of gland function might cause hyperplasia in the breast when active over a number of years and yet not be obvious when studied by relatively crude laboratory methods over a month's time. Irregularities in the peaks of production or excretion of estrogen may furthermore have a significance quite aside from the total quantities chiefly discussed in this paper. Finally, it is possible that the abnormal estrogenic effects on the breasts may be the result of local conditions, such as an increased responsiveness to normal quantities of the hormone, possibly as the result of local hyperemia, or a tissue concentration of the gland substances bearing no relation either to the actual activity of the ovary or to the amount of estrogen in the blood stream. A summary of the present knowledge of the conditions under which chronic mastitis is found to develop is presented.

**Elimination of Pain After Rectal Operations.**—Kilbourne presents measurements of the local irritation and of the duration of local anesthesia produced by various agents. From the laboratory observations quinine urethane solution appears to be superior to all other known local anesthetics of prolonged action because, when such solutions, in the highest concentrations that can be used without sloughing are compared quinine urethane solution gives the longest anesthesia. Clinical experience however, raised an unexpected difficulty when quinine urethane solution was used for infiltration in operative surgery it prolongs the bleeding time so that the wound may ooze for

two or three days. For this reason it was abandoned in operative surgery. On the other hand, quinine urethane has justified expectations for the purpose of injection of anal fissure. It can be used in a higher concentration without sloughing than can quinine urea dihydrochloride. It is more stable and, most important, it does not cause such severe pain on injection as quinine urea dihydrochloride. Of course any anesthetic solution, even procaine hydrochloride, will cause pain if injected under some hypersensitive fissures, but quinine urethane solution is much less likely to cause pain than quinine urea dihydrochloride. It is now being used in a concentration of quinine hydrochloride from 1 to 3 per cent, with urethane in half the concentration of the quinine. Usually 1 or 2 cc is injected under a fissure. Quinine urethane solution may also prove of value in the injection treatment of pruritus ani. The supersaturated solution of quinine urethane used for varicose vein injection is too strong for any of these purposes. After 100 rectal operations, patients were told that they could have morphine or codeine. Of these, fourteen wanted one dose of narcotic, thirteen wanted more than one dose, while seventy-three did not want any narcotic at all.

**Observations on Mobile Colon**—Cade has been through the gamut of attacking a chronically inflamed appendix and of dilating supposed strictures of the ureter without relief of right-sided abdominal pain. Later he began to study ptosis with the free and movable colon and its treatment as advocated by Waugh and Coffey. He did not get the results that he believed the patient was entitled to, but some relief was secured in the majority of cases. This caused him to think that there was some value in what was being done, but as yet the proper attack had not been made. Then one day he operated on a woman suffering from acute pain in the right side severe enough to require morphine for relief. He had previously removed the appendix at the time a hysterectomy had been done for fibroid tumor. The patient did not have intestinal obstruction because a barium sulfate meal went through the intestine in the proper period of time. A pendulous mobile colon twisted on itself was found. There was a distinct twisting to the left of the colon just below the hepatic flexure with subsequent kinking of the ileum at the ileocecal valve. The condition was not severe enough to cause obstruction and the intestine was normal in color. Three interrupted sutures were taken through the lateral white line of the cecum to the parietal peritoneum and tied. This was sufficient to give a hobbling effect to the colon, but certainly not enough to support its weight and prevent ptosis. It did give, however, a straight terminal ileum so that it entered the colon approximately at a right angle as it should and was sufficient to prevent the intestine from twisting on itself again. The patient has not had any recurrence of symptoms in six years. Since that time the author has been doing this simple operation in cases in which right-sided pain could not be attributed to other causes, with the result of apparently complete relief from the pain generally a cessation of the nervous systems and a gain in weight. Because of this fact he has concluded that it is not the ptosis of the intestine or the ptosis of the ascending colon that is causing the trouble but rather the rotation permitted by its insufficient attachments with resultant twisting and narrowing of the lumen of the intestine just below

the hepatic flexure and more or less ballooning or dilatation of the head of the intestine, accompanied by kinking of the terminal ileum caused by twisting of the intestine.

**Pleural Adhesions in Pulmonary Tuberculosis**—Drash and Nicholls restate that the operation of closed internal pneumonolysis has been designed to convert an ineffective pneumothorax into a good one by dividing the offending adhesions. The operation consists of the insertion, under local anesthesia, of the thoracoscope through an intercostal puncture. The adhesions are then visualized directly and divided by means of the high frequency current. The ideal result if the operation is accomplished is the immediate collapse of the lung with the well known therapeutic effect of a successful pneumothorax. The authors report the results of 129 cases, from seven different sanatoriums, which represent all possible types of adhesions and variations in the condition of the patients. Many of them were far advanced and extremely poor operative risks. Of the 129 cases, only seven were totally unsuitable for the division of adhesions. The inoperability was based either on the type of adhesions or on the presence of extensive pleural tuberculosis. Of the seven inoperable cases, two later had a thoracoplasty with excellent results. One case required an open operation to divide the adhesions successfully. A clinically satisfactory collapse was obtained in 90.8 per cent of cases. A much higher percentage of good results was obtained in the group that showed extensive soft infiltration but without cavity formation. The division of adhesions has been accepted rather slowly by the profession, owing to the fear of complications or dangers of the procedure. That fear of the operation is unjustified is shown by the results. The operation of closed internal pneumonolysis carries much less risk and a lower operative mortality than does thoracoplasty. When a good pneumothorax can be obtained it is always preferable to a thoracoplasty. Hemorrhage has been of minor importance. The danger of empyema is also minimal. There is a definite tendency as experience increases to attempt the section of more difficult and complex adhesions. However such cases can best be handled by dividing the procedure into two or more stages. In several patients with diabetes it was noted that, after the adhesions were divided and the tuberculosis was improved, the patients' carbohydrate tolerance also was improved. This may have been due to improvement in digestive function, due in turn to a decrease of tuberculous toxicity. No cases showing intrapleural adhesions were considered for operation unless it was the firm conviction of the physician in charge that the adhesions were seriously interfering with the patient's progress, and further, that the degree of collapse was unlikely to be improved by continuation of the pneumothorax unless the adhesions could be divided. No patient should be denied the benefit of the procedure if his adhesions are of a suitable type for severing.

**Further Observations on Disturbance of Metabolism Caused by Injury**—In the course of clinical studies Cuthbertson made attempts to prevent the loss of nitrogen that occurs during the period of increased catabolism following severe injuries due to direct violence. He observed that the ingestion of diets very rich in first class protein and of high caloric value by persons suffering from the fracture of one or more of their long bones as the result of direct violence considerably modifies the marked loss of body protein that normally occurs under such circumstances. At the height of the catabolic disturbance, however, such diets still fail to prevent this loss of protein. Measures, such as massage and manipulation, the addition of meat extractives, aminoacetic acid, hydrolysate of mixed or tissue, gelatin and sodium caseinate, and diets of high caloric value but average protein content, similarly failed to stem the loss of protein and generally proved less successful in mitigating the drain on the body's reserves. The catabolic disturbance is characterized by an increase in the basal consumption of oxygen with an attendant rise in pulse rate and temperature, and by parallel rises in the urinary output of nitrogen, phosphorus and sulfur and, to a less extent potassium. The creatinuria that develops and parallels the rise in total nitrogen is accompanied by little change in the creatinine excretion, such change as occurred took the form of a slight diminution during the period of maximal creatinuria. Two control subjects who received diets rich in first class protein and of high caloric value exhibited nitrogen equilibrium.

**Renal Rickets and Dwarfism**—In the last two years Chown has seen two babies, sisters having from birth deformities like those of severe rickets. A few days after birth they began to have curious spells of sham joy. Both had a hypercalcemia but normal or slightly reduced phosphatemia without discernible progressive decalcification of the skeleton. One died at 3 months and the other at 6. Both had early pathologic changes in the kidneys which would have led to chronic nephritis. At first the author thought that these were cases of congenital osteitis fibrosa cystica, but he now believes that the two children were suffering from a form of the disease variously called renal rickets dwarfism or infantilism. If this is true the cases add weight to the opinion that these diseases are due to endocrines running amuck, the kidneys being but innocent bystanders. His argument in proof of the thesis that a lesion of the pituitary-diencephalic mechanism is the primary cause of the symptom complex called renal rickets is as follows:

- 1 Malformation of the pituitary has been found in these cases.
- 2 The associated symptoms of dwarfing, polyuria, infantile and urinary tract dilatation can be caused by such a lesion.
- 3 The nephritis is not primary but is secondary to an abnormal mineral metabolism, itself the result of faulty bone growth.
- 4 The faulty bone growth therefore not being due to the nephritis, and the remaining symptoms being due to pituitary-diencephalic disease, it is to be presumed that the bone disease is due to the same cause. Should this argument prove correct, it offers some hope for these previously hopeless cases, for substitution therapy could in theory produce normal bone growth in the springing-up periods and so save the kidneys.

**Treatment of Acute Intramammary Abscess, by Incision and by Aspiration**—Battle and Bailey describe a method of aspirating breast abscesses and washing them out with dilute solution of sodium hypochlorite. The solution has been found to give good results. They review the whole series of cases and attempt some impartial judgment between the merits of incision and those of aspiration. 1 The aspiration of an abscess can be performed single handed without skilled assistance. The anesthetic employed is a local one, there is no wound to be dressed afterward and the cooperation of a nurse becomes unnecessary. Scarring is reduced to a minimum, and consequently the ultimate cosmetic and functional result is of the best. Aspiration is therefore to be preferred in cases of suppuration occurring in the nonlactating breast and in cases in which, during lactation, the abscess is relatively localized and confined to one lobe. 2 With the large abscess and neglected breast, incision immediately relieves an already prolonged toxemia and drains a large cavity more satisfactorily than can aspiration. 3 With the diffuse, cellulitic type of infection the prognosis is poor, however the condition is treated. Incision is probably to be preferred, in that by this means the local condition can be explored thoroughly with the finger and infected areas broken down into one large abscess cavity. 4 The author advises aspiration if there is any doubt as to the treatment necessary in any particular case. In any case incision can always be resorted to with failure to settle after several aspirations, and only time is lost.

**Potassium Permanganate Poisoning**—Willmott and Freeman point out that although potassium permanganate is one of the safest disinfectants when used in proper strength dilute solutions may irritate the stomach, and concentrate solutions may even induce gastroenteritis. Abortion has resulted during early pregnancy, following a vaginal injection of a strong solution of permanganate. The toxic effects of potassium salts on the heart muscle and the central nervous system have been ascribed by pharmacologists to the potassium ion, and this would seem to be the case with potassium permanganate. The fatal dose is not known, but 20 Gm has proved fatal when injected through the urethral canal. Consideration of its many uses emphasizes the necessity for its application in the correct dilution for the particular purpose.

**Incidence of Pleural Effusion in Artificial Pneumothorax**—Rosenthal advances the thesis that trauma to the pleura in one way or another, is the main provocative cause of pleural effusion in artificial pneumothorax. A cursory examination of the literature shows that there exists a great variety

tion (from 5 to 70.38 per cent) in opinion regarding the frequency of pleural effusion complicating artificial pneumothorax. The discrepancy is partly due to the deliberate exclusion from their figures by some observers of those cases in which only a small effusion was observed. The indication is that the proportion of affected cases averages about one half, but until some more careful standardization of results is attempted any accurate forecast will be impossible. The incidence of empyema appears to vary from one in eight to one in four of cases in which fluid has developed, that is, from 5 to 10 per cent of cases in which artificial pneumothorax has been established. Of the author's fifty-four patients who received artificial pneumothorax therapy for the treatment of pulmonary tuberculosis, forty-one, or 76 per cent, developed effusion. If those are excluded in which only a small "puddle" of fluid formed, filling the costophrenic angle, the number of effusions was twenty-three, or 43 per cent. He concludes that the occurrence of pleural effusion in artificial pneumothorax is due to the combination of the factors of trauma to the pleura and infection, which may occur separately or together. It is supposed that small effusions are due only to trauma and are "reactionary," that larger effusions are due to trauma accompanied by infection, and that a relatively small proportion of effusions are due to tuberculous pleurisy. No medicinal treatment should be given. There should be a careful selection of cases for artificial pneumothorax. Care in refills should be taken when artificial pneumothorax is established, regular screening being regarded as essential. Positive pressures, or attempts to "compress" the lung should be avoided. Artificial pneumothorax should be abandoned if collapse is unsatisfactory before complications occur. When effusion is present there is no medicinal treatment of proved value. The use of calcium has again been invoked. If the quantity of fluid is small and not disturbing the patient, refills should be continued with careful observation, and there should be occasional aspiration of a small quantity of fluid to note possible change in character. If a large effusion is present one should aspirate it and replace it with air as infrequently as necessary. If collapse is poor, artificial pneumothorax should be abandoned in favor of other surgical measures. If the fluid does not constantly reaccumulate and collapse is good, refills should be continued as required. If the fluid is or becomes purulent, the treatment is surgical.

**Acetylsalicylic Acid Poisoning**—Neale points out that the onset of recognizable symptoms of acetylsalicylic acid poisoning is usually delayed for a few hours, this interval probably bearing direct relation to the rate of absorption of the drug. Although gastro-intestinal irritation with associated vomiting may occur, the leading clinical disturbance is connected with the nervous system and, in the untreated case, reaches its peak in the course of twelve hours or more when dissolution may take place as a result of profound cerebral depression. Progressive diminution of function can be traced from the higher to the lower nerve centers. Disturbance of heat regulation occurs, and profuse sweating may be regarded as an important clinical sign in the diagnosis. The type of respiration seems to vary in different cases, and typical 'acidosis' breathing is not invariably seen. The toxic effects of acetylsalicylic acid are potentiated by associated dehydration, which is likely to reach a major degree as a result of the respiratory changes, the very considerable perspiration and the prolonged effects of the drug. Auditory and vestibular disturbances are conspicuous in some cases. Reference to the patient's mental state, the presence of severe perspiration and of respiratory changes, and examination of the urine for salicylic acid should enable the diagnosis to be made. A period of several hours usually elapses before dangerous cerebral phenomena arise. Acceleration of the latter signs may occur in a person debilitated by previous chronic disease. The dangerous dose of acetylsalicylic acid varies from 400 to 500 grains (26 to 32.5 Gm.), but, in the light of more recent observation on the beneficial results of treatment, a lethal effect may be avoided even when more than 500 grains is ingested. The visceral action of the drug is considerably intensified by the associated dehydration and it is therefore imperative to combat the depletion of tissue fluids and especially to encourage and retain adequate renal secretion. If enteral fluid cannot be received the continuous intravenous drip method (dextrose-saline solution) should be used. Excretion of the acid

occurs in the sweat and the urine. The cerebrospinal fluid contains the drug in considerable amounts, and lumbar puncture undoubtedly played a leading part in the recovery of two patients. No such treatment, however, was carried out in the four fatal cases. It seems reasonable to believe that, even when symptoms and signs in this form of poisoning have reached an advanced stage, the combined therapeutic effect of the introduction of fluid to the body and the simultaneous aspiration of the cerebrospinal fluid will be a means of saving an otherwise hopeless situation.

**The Sherrington Phenomenon**—Bulbring and Burn observed that after degeneration of the motor nerve supply a contracture of the gastrocnemius muscle of the dog and the cat can be obtained by stimulation of the lumbar sympathetic chain. Thus the Sherrington phenomenon is due to the stimulation of the sympathetic fibers in the sciatic trunk. The contracture that occurs when the chain is stimulated is much more readily seen in dogs than in cats, since the cholinergic dilator fibers are much more numerous in dogs than in cats, the authors' evidence supports the view that the contracture is due to the liberation of acetylcholine from the endings of the sympathetic vasodilator fibers. The denervated muscle of the leg responds to an injection of epinephrine by a slow prolonged contracture, though this is not always seen unless ergotoxine is injected previously. Stimulation of the sympathetic chain liberates epinephrine (or sympathin) as well as acetylcholine. The liberated epinephrine reduces the rise of tension in the muscle caused by acetylcholine but it also causes a second late rise of tension. The reduction of tension is well seen after phosostigmine when the prolonged effect of acetylcholine is broken by a period of reduced tension into two phases. The rise of tension caused by the liberated epinephrine is readily seen after ergotoxine, as a second rise following the rise due to acetylcholine.

**Vasoconstriction Following Deep Inspiration**—During the study of vasomotor reflexes in the limbs of man by means of plethysmographic records, Bolton and his associates encountered a reflex associated with respiration. In a series of experi-

ments on more than twenty healthy young female and male adults it was observed that a diminution in volume of the digits was recorded without any known stimulus having been given to the subject. It was found that this occurred immediately following a sigh. This diminution in volume took place in the digits of all four limbs synchronously in from two to three seconds after the commencement of the sigh. The alteration in volume so described is entirely different from, and of larger amplitude than, the changes seen during normal respiration. An exactly similar diminution in volume of the digit was obtained on requesting the subject, either verbally or by a signal to take a voluntary deep breath imitative of a sigh. The time relation to the respiratory changes was in every way similar to that obtained following a sigh. By utilizing the imitative sigh or voluntary deep breath, the mechanism of the diminution in volume was further investigated. In one subject in whom the right brachial plexus was completely torn across eighteen months previously, no diminution in volume occurred in the digits of the denervated limb following a deep breath although it still occurred as in a normal in the digits of the other limbs. The diminution in volume of a digit is therefore dependent on the integrity of peripheral nervous pathways. In two subjects in whom the stellate ganglion had been removed by operative procedure the digit of the sympathetomized limb did not show any evidence of diminution in volume on deep breathing. The alteration in volume was encountered in the other three limbs. Similarly in a subject with the lumbar sympathetic ganglions removed no response was obtained from the digits of that limb, although the digits of the other limbs reacted normally. It thus appears that the diminution in volume of a digit associated with deep breathing is dependent on the integrity of the peripheral sympathetic system. The experiments also rule out the possibility of movement of the digit within the container being the cause of the recorded volume diminution.

**Diabetes Mellitus**—Himsworth thinks it probable that in cases of insulin-sensitive diabetes mellitus the cause of the disease is deficiency of insulin, while in insulin insensitive cases the cause of the disease is not lack of insulin but the restriction of an unknown sensitizing factor. Work on healthy men and animals demonstrated the existence of a factor rendering the body sensitive to insulin. When more carbohydrate is given to a healthy subject the body reacts by rendering itself more sensitive to insulin. When more carbohydrate is given to an insulin-sensitive diabetic person the insulin requirement does not increase and glycosuria does not appear. This apparent increase in efficiency of the injected insulin can be explained satisfactorily on the basis that these patients react to the increased amount of dietary carbohydrate by becoming more sensitive to the injected insulin. But in the case of the insulin-insensitive diabetic patient increased intake of carbohydrate results in glycosuria and consequent increased insulin requirement. Thus, these patients are abnormal in being unable to react to increase in dietary carbohydrate by increase in their sensitivity to insulin. It appears justifiable therefore to regard the insulin-insensitive type of diabetes as being due to lack of that same unknown factor which in the normal subject produces sensitivity to insulin. The author suggests that this insulin-sensitizing factor is an activator of insulin, but as yet there is no incontrovertible evidence whether the unknown is a factor in the sense of being a definite substance or a condition of the tissues in general that facilitates the action of insulin.

However, the nature of the unknown "insulin sensitizing factor" must be such that it is intimately concerned with the action of insulin and that its restriction will result in rendering a proportionate amount of the available insulin powerless. For distinguishing these two types of diabetes mellitus the patient receives no food or insulin after supper the previous evening, and the test is carried out next morning. Blood sugar estimations are performed on capillary blood. Three resting samples are taken. The patient is given the appropriate dose of insulin intravenously and immediately afterward the appropriate dose of dextrose orally. A blood sample is taken five minutes after the insulin injection and the next at ten minutes, subsequent samples are taken at intervals of ten minutes until the hour is reached, and then two more samples at intervals of fifteen minutes. The test is thus completed in ninety minutes. The author allowed 30 Gm of dextrose and 5 units of insulin to each square meter of body surface. The test must not be carried out if the patient shows signs of nausea or faintness. In these cases absorption from the stomach is delayed and a fallacious result obtained. If it is desired to compare a series of curves, the patients must all be receiving diets containing approximately the same amount of carbohydrate, as the insulin sensitivity of a normal subject is determined by the amount of carbohydrate utilized. Conditions of exercise will very probably affect the test. In the insulin-insensitive patient the insulin has little effect, while in the insulin-sensitive patient not only is the hyperglycemia suppressed but an actual depression of the blood sugar level is produced.

**Streptococcal Septicemia Treated with Injections of Whole Blood**—Hendry and Griffiths adopted the use of whole blood, as suggested by Lazarus-Barlow and Chamberlain, instead of streptococcus antiserum in the treatment of a patient suffering from streptococcal septicemia who was seriously ill and whom it seemed inadvisable to remove to the hospital. The procedure used was the injection of 15 cc of whole blood taken from the patient's husband and its immediate injection into the thigh. No apparatus was required other than sterile needles and syringe, nor was blood grouping necessary. Although there was a slight fall in temperature after each injection of streptococcus antitoxin there was little improvement clinically. This may have been due to the absence from the antiserum of the specific antibody corresponding to the bacterium infecting the patient. Each injection of whole blood from the donor immunized with an autogenous vaccine caused profound improvement, and the injections seemed to precipitate the formation of localizing abscesses in the red patches that appeared at the onset of the illness. As the antihemolysin titer of the serum increased only from 75 to 250 units, it is doubtful whether any improvement can be attributed to the antihemolysin. The possibility of complement cannot be neglected, for it has been found by Cadham that in acute infection the complement titer may be low during the acute phase of the disease. The introduction of complement by the way of whole blood from a healthy person may in this case have done much to combat the infecting organism.

## Extirpation of Ganglions in Cancer of Clitoris—

Hausen describes a case of primary malignant tumor of the clitoris. The patient was 58 years of age. Primary cancer of the clitoris represents about 4 per cent of the vulvar cancers. It is more malignant than neoplasms of the vulva because of the richness of the blood and lymphatic vascular systems of this region, which favors metastases to the inguinal and pelvic ganglions. The clinical determination of ganglion involvement is practically impossible, histologic examination alone can determine this point. It is for this reason that an early surgical intervention is necessary. Surgery should involve wide amputation with complete and methodical curettage of the ganglions bilaterally. If circumstances permit, it is wise to complete the treatment by postoperative roentgen therapy.

## Subcardiac Diverticula of Stomach—Cain and Guttmann

limit their discussion to diverticula of the stomach that are strictly juxtacardiac. They consider them to be primary congenital noninflammatory formations and wholly different from those developing in the course of ulcer or neoplasm or the pseudodiverticula created by diaphragmatic herniation of the stomach. The subcardiac diverticula are characterized by the constancy of site of their insertion. They are fixed under the heart on the posterior surface of the lesser curvature. The orifice of the canal opens in the stomach at a distance of from 0.5 to 4 cm from the cardio-esophageal junction. Their size and mobility vary. They are partial or total depending on whether they represent an evagination of the mucosa through the muscular layer or whether they comprise all the coats the muscular being reduced to a thin layer. From the clinical standpoint the majority are symptomless. Occasionally postprandial sensations may call attention to the stomach. The roentgenologic appearance, with the patient in different positions, appears as a pure image without cardio-esophageal reaction or modification of gastric function. Complications are few and mechanical or inflammatory ones have not been noted. Neoplastic transformation is known however. The differential diagnosis of this condition is impossible on clinical grounds. The principal roentgenologic problems are transdiaphragmatic herniations of the stomach, epiphrenic esophageal diverticula and some subdiaphragmatic lesions, such as air in the colon, perigastritis, and ulcer or cancer of the superior pole of the stomach. There are three principal theories of pathogenesis: congenital reflex and mechanical. Surgical treatment is not indicated unless necessary for concomitant disorders. Administration of bismuth subnitrate is usually followed by swift subsidence of the unpleasant symptoms.

made determinations of the gastric secretion following either gastro-enterostomy or gastric resection in duodenal and gastric ulcers. The determinations were made before and after performance of the operation in the latter case at short and long intervals after it. The author says that the gastric hydrochloric and total acidities diminish much more after gastric resection than after gastro-enterostomy. The intensity in the lowering of gastric acidity following gastric resection is independent of the type (duodenal gastric or

jejunal) of the ulcer as well as of the technic (first or second Billroth operations) used in reestablishing the continuity of the digestive tract. The lowering of the gastric acidity is due to modifications of the gastric secretion produced by resection and not to neutralization of the secretion by the presence of either bile or alkaline fluids, backing up through the neostomy. The gastric hypo-acidity is maintained for a long time after resection and sometimes increases as time elapses.

## Metabolism of Oxalic Acid in Relation to the Liver

—Pennetti states that there is a relation between the content of oxalic acid and oxalates in the blood and the functions of the liver. Hyperoxalemia during fasting is frequent in patients suffering from liver diseases. An oral dose of 25 Gm of sodium oxalate, given during fasting, does not modify oxalemia in normal persons, while it causes either appearance or increase of hyperoxalemia in patients with liver diseases. The author determined the oxalemia in fasting rabbits and dogs in which the renal functions were normal. He found that in normal rabbits fasting oxalemia does not increase or slightly decreases after an intravenous injection of a 3 per cent solution of sodium oxalate, in the proportion of 0.03 Gm of sodium oxalate per kilogram of the weight of the animal. Oxalemia greatly increases after injury of the liver (caused by intoxication of the animal, by hydrazine sulfate or by ligation of the common bile duct) or exclusion of the organ (caused by ligation of the hepatic duct), whether or not the animals are given the sodium oxalate test. From a clinical point of view, the results prove that the liver is not the only organ involved in the manufacture of oxalic acid and its oxalates and that fasting hyperoxalemia of patients with liver disease is a metabolic disturbance due to insufficiency of the liver and not to retention of oxalic acid and its oxalates in the blood because of renal insufficiency.

\*Pneumococcal Peritonitis in Infants Case I Diaz Bobillo—p 592

**Removal of Stellate Ganglion—Caeiro** says that the removal of the upper cervical ganglion (Leriche's operation) has been considered an operation that offers satisfactory results in the treatment of traumatic paralysis of the facial nerve. The operation results in the appearance of voluntary contraction of the orbicular muscle increased turgor of the facial structures of the paralyzed side and correction of the facial asymmetry. The appearance of the Bernard Horner syndrome is a new factor for correction of facial paralysis. Several theories, such as the existence of a crossed innervation of the upper facial nerve, the suppression of the muscular tonus and the production of a permanent vasodilatation, were given as an explanation for the effects of upper cervical sympathectomy. Nevertheless the author considers upper cervical sympathectomy a segmentary operation with transient results after which the patient may return to the same condition in which he was before performance of the operation. The author reports satisfactory results in a case of traumatic paralysis of the facial nerve, from resection of the stellate ganglion, which results in complete elimination of the sympathetic innervation of half of the head and neck. In his case the satisfactory results are still lasting eleven months after performance of the operation.

**Pneumococcal Peritonitis in Infants—Diaz Bobillo** states that pneumococcal peritonitis is rare in infants. He reports seven cases in infants from 6 months to 2 years of age. The condition was primary in two cases secondary to other locali-

zations of the pneumococcus, such as pneumonia, pleurisy and pericarditis, in three cases, and associated with pleuropulmonary pneumococcal infection in two cases. The diagnosis of pneumococcal peritonitis is difficult. It has to be differentiated from dyspeptic coma, appendicitis, typhoid and tuberculous peritonitis. The performance of abdominal puncture for diagnosis is dangerous. As a rule the infection is associated with pleural, pulmonary, meningeal and pericardial pneumococcal infections and the prognosis is fatal in nearly all cases. The treatment includes infra umbilical laparotomy under procaine hydrochloride anesthesia, followed by drainage. Before and after the operation the administration of large doses of antipneumococcus serum intramuscularly, cardiac tonics and stimulants is advisable. The type of the disease in all the cases reported by the author was grave and the evolution fatal.

Strangulation of Intestine in Mesenteric and Mesocolic Openings F Landois—p 241

**Talma's Operation**—Henningsen reports seventeen cases of ascites in which the Talma operation was performed. Six of the patients who had icterus and an advanced cholemic state died within a few weeks after the operation. In one case presenting icterus for a short time the ascites did not recur for one year after the operation. In three cases without icterus but with a long standing history, temporary relief was obtained. No results were obtained in two cases of ascites and anasarca of cardiac origin. Fairly good results were obtained in five cases which presented no icterus and a relatively short history and in which few abdominal punctures were made at long intervals. The author concludes that the Talma operation is indicated only in cases in which ascites is due to obliteration of the central veins of the portal circulation. The indications are further influenced by the duration of the disease and the functional condition of the liver. The disease progresses rapidly after the appearance of ascites or gastric hemorrhages. The operation should not be long delayed after the appearance of these symptoms. Appearance of icterus, acholia, urobilinuria and pigmentation of the skin points toward a bad prognosis. The author cites experiments to show that rats did not survive ligation of the portal vein when their livers were primarily impaired by phosphorus feeding. Gastric hemorrhage from an esophageal varix constitutes an urgent indication for operation. Clinical experience demonstrated that collateral circulation in such cases can be improved by the Talma operation and a fatal hemorrhage prevented. The author feels that the operation should be performed more frequently since it does little damage, can be carried out under local anesthesia and in properly selected cases offers amelioration of at least one symptom, that of ascites in an otherwise incurable disease.

\*Results of Operative Intervention for Perforation of Gastric Duodenal Ulceration G Haussler—p 206  
Surgical Roentgenology R Janker—p 214

**Operations for Perforation of Gastric Ulceration**—Haussler analyzes the results of 151 operations for perforation of gastric duodenal ulceration performed in the clinic of Prof W Keppler of Essen from 1920 to 1935. There were six women in the group (4 per cent). Operation was performed in 70 per cent of the cases within the first six hours after the onset of symptoms and in 165 per cent within the first twelve hours. The total mortality rate was 26.5 per cent. The mortality rate in the group in which operation was performed within the first six hours was 15.4 per cent and that of the first twelve hours, 17.6. In the group in which operation was performed after twelve hours it was 69 per cent. A follow-up study was made in eighty-nine cases and an x-ray study in seventy-three. In twenty-nine of the patients there developed

an incisional hernia and in thirteen a mild distasis of the rectus muscle. The mortality in a group of twenty-eight patients in whom suture of the ulcer alone was practiced amounted to 17.1 per cent. In a group of eighty-three patients in whom suture of the perforation and a gastro-enterostomy was practiced the mortality amounted to 18.1 per cent, and in a group of twenty-two having partial gastric resections the mortality was 22.7 per cent. Only one fifth of the patients in whom a gastro-enterostomy was performed were free from complaints. In eight there developed a peptic jejunal ulcer. Of these, one died of a profuse hemorrhage and the remaining seven were submitted to the operation of partial gastric resection. In the group in which suture of the perforation was performed, half the number were free from symptoms. Pyloric stenosis occurred in five. The results in the group in which partial gastric resection was practiced were better, more than half of these were symptom free and the remaining complained of mild symptoms on ingestion of a heavy meal. The patients who were not working were more likely to have complaints than those who returned to work. The authors have abandoned in the late years the addition of gastro-enterostomy because of the poor results. They consider simple suture of the perforation the operation of choice and reserve the later operation of partial gastric resection for cases exhibiting more serious complications or symptoms.

\*Audible Auricular Sound in Auricular Flutter H Ludwig and A Bener—p 271

**Creatinuria in Cardiac Decompensation**—Kindler shows that considerable changes take place in the metabolism of patients with cardiac decompensation. He found creatine in the urine in all cases of severe cardiac insufficiency and also observed that it disappears again as the circulatory conditions improve. This creatinuria is the result of a decomposition of glycogen, which in turn can be traced to an inadequate oxygen supply of the skeletal musculature during the cardiac decompensation.

**Audible Auricular Sound in Auricular Flutter**—Ludwig and Bener assert that no sound corresponding to the auricular action is audible in the case of normal cardiac activity. However, in many cases of atrioventricular block the auricular action is accompanied by audible sounds and some cases of gallop rhythm of mitral stenosis particularly the presystolic gallop rhythm, may likewise be due to the fact that the auricular action becomes audible. That the rapid action of auricular flutter may become audible was previously unknown. The case observed by the authors throws light on the origin of the auricular sound. A man, aged 40, had cardiac insufficiency, mitral and aortic insufficiency, auricular flutter, complete atrioventricular block, disordered intraventricular conduction and stasis cirrhosis. In addition to a loud first sound, a loud systolic murmur, a clapping second sound and a low diastolic murmur, a dry, somewhat woody sound, of high frequency and regular rhythm could be heard. The maximum audibility was on the left parasternal line in the second and third intercostal spaces. In the median and downward direction, the intensity of this sound decreased. Immediately after the second sound the rhythm was weak, but in the course of the ventricular diastole it became constantly louder. In the case of simultaneous registration of the electrocardiogram and of the cardiac sounds there appeared between the second and first cardiac sounds, that is, during the ventricular diastole, regular oscillations, the frequency of which corresponds exactly to that of the auricular action. The authors were unable to detect this sound in other cases of auricular flutter. A mitral insufficiency exists, but muscular insufficiency may play a part here. It is possible that the aortic insufficiency with its increased rest quantity of blood plays a part. The increase in the intensity of the sound during the ventricular diastole, that is, during the further increase of the ventricular filling, favors this possi-

bility At any rate, this case contradicts the origination of the auricular sound in the ventricle, as has been suggested by Gallavardin and Duchosal. The authors ascribe the development of the auricular sound to oscillations of the auricular wall, which, as Weber suggested, are caused by the sudden transition from the flaccid diastolic to the taut systolic condition or, as suggested by Edens, by the forced position of one of the valves in the course of the auricular systole

Why Is Theory of Spontaneous Tear of Meniscus Untenable? F Linde—p 286  
Method for Quantitative Determination of Pepsin in Commercial Products H Eschenbrenner—p 288

**Treatment of Myocardial Impairment**—Gotsch first discusses the group of myocardial defects most often caused by failure of the regulation of the coronary blood perfusion. In these disorders one must overcome the disturbance in the blood perfusion and reduce the blood requirements. The blood perfusion is improved by nitrites and by the intravenous injection of concentrated solutions of dextrose. These measures, together with physical and mental rest, often counteract the coronary insufficiency. However, if the nitrites fail and the enforcement of rest proves difficult, strophanthin therapy may eventually be resorted to. For the treatment of the myocardial infarct that may develop in the course of coronary thrombosis the author recommends complete rest, morphine during the attack and hot baths for the hands. However, if signs of cardiac insufficiency appear, strophanthin may be used. The doses should be small (from 0.1 to 0.2 mg. if necessary repeated on the same day). The injection must be made slowly and should be combined with a 40 per cent solution of dextrose, eventually with a small addition of theophylline ethylenediamine. After the acute attack has passed, several weeks of rest should be enforced. If the anginal attacks return, nitrites and, if necessary, strophanthin may be given. In discussing the disturbances in the cardiac rhythm which developed in the course of coronary sclerosis, the author points out that the regulation produced by quinine is usually of only short duration. This and other disadvantages of the quinine therapy have promoted the wider use of digitalis or strophanthin, which likewise counteract the undesirable circulatory effects of arrhythmia and yet do not have the unfavorable effects of quinine. The author pays attention to the Adams Stokes attacks. He shows that if possible the etiologic factors should be determined. If they are inflammatory and likely to regress within a few days, efforts should be made to reestablish the normal stimulus conduction by the administration of an isomer of ephedrine (0.05 Gm. from three to five times) and caffeine and by the treatment of the existing rheumatism or septic foci. However, if conditions exist that result in progressive impairment of the heart (coronary sclerosis), the improvement obtained by these remedies will be of only short duration, and it will be better not to aim at the reestablishment of a normal rhythm but rather to administer digitalis preparations and thereby change the temporary interruption of the conduction into a permanent one (continuous ventricular automatism). However, if the Adams-Stokes attack develops in the course of an already existing ventricular automatism the fatigued center in the ventricle must be stimulated by barium chloride and caffeine. For the treatment of paroxysmal tachycardia, quinidine is usually advised, although strophanthin is being used more and more.

**Functional Diagnosis of Intermittent Claudication**—Kisch asserts that observations in the work test indicate a relationship between angina pectoris and intermittent claudication. After calling attention to his earlier report on angina pectoris during the work test (abstracted in THE JOURNAL, Oct 5 1935, p. 1155), he points out that a defective capillarization seems to play a part in both conditions. As he had studied angina pectoris by means of a work test he now decided to

employ a work test for intermittent claudication. Whereas in angina pectoris the standard exertion of the work test consisted in sitting up from the horizontal position and resumption of the reclining position, he chose as standard exertion for intermittent claudication a maximal bending at the ankle, knee and hip joints (as far as possible with adduction of the knee to the abdominal wall), with immediately following maximal extension of these joints, while the body of the patient is in the horizontal position. This bending exercise is done thirty times a minute. The number of times this standard exertion is performed before an attack of claudication results is designated as the threshold value for the pain of claudication. The author found that this value varied considerably in different patients. If the value is rather high, it may be assumed that the capillarization defect has not progressed far or that it has been compensated to a considerable extent by the formation of collateral arteries. If the work test reveals a rather low threshold value the capillarization defect of the involved muscles is probably considerable. The increase or decrease in the threshold value indicates an improvement or an exacerbation of the disorder.

**Possible Transmission to Offspring of Lymphogranuloma Inguinale**—Dick states that women with the late forms of inguinal lymphogranuloma are often sterile but occasionally give birth to mature infants. In the latter case the fate of the offspring is of interest. The author reports two cases. One concerns a woman with a positive Frei reaction and rectal stricture who became pregnant and gave birth to a normally developed infant, who had a positive reaction when subjected to a Frei test two weeks after birth. Moreover, at five months the test was again positive. The second case cited by the author concerns a girl, aged 14, the daughter of a woman who had died following an attempt to dilate a rectal stricture, the latter being doubtless the result of an inguinal lymphogranuloma. The daughter had complained of rectal disturbances for a number of years, Frei's test was positive, indicating that her rectal disturbances were due to inguinal lymphogranuloma. In this case three modes of transmission were possible: intra-uterine infection, infection during the process of birth and infection after birth by contact with the mother. In the nursing, however, the infection must have taken place before or during birth. The author points out that intra-uterine transmission seems likely in view of the fact that in adults the Frei test does not become positive until several weeks after the infection and that the nursing had a positive Frei test two weeks after birth.

New Methods in Treatment of Vomiting of Pregnancy W Schmidt—p 357  
Exercise Treatment in Spondylarthritis Ankylopoietica (Bechterew) C Keiffenheim—p 358

**Biology of Herpes Simplex**—Naegeli points out that since 1920 herpes simplex has been generally regarded as an infectious disease. He admits that in view of the fact that experimental transmission of the disease is possible the infectious nature cannot be questioned since transmissibility of a disease is considered equivalent to causation by a living agent. However, he shows that if the biologic nature of herpes simplex is studied with great care many factors are discovered that do not tally with the bacterial nature of the disorder. He mentions the influence of puberty, particularly in females, the familial appearance in which constitutional factors seem to play a part,

and finally the greater incidence in women. He describes the peculiarities in its appearance and course pointing out that in the majority of cases herpes appears following some unusual external or internal happening (acute febrile infectious diseases, gastro-intestinal disturbances, incretory disturbances menstruation, trauma, physical exertion or shock). Nevertheless herpes simplex cannot be compared with the activation of other infectious diseases, for only in some of the cases does the herpes develop toward the end of the primary disease. Quite often herpes simplex signifies the onset of a disease. The precipitousness of the onset of herpes simplex is demonstrated, particularly in fever therapy with vaccines and in malaria therapy. Occasionally the herpes blisters appear during the first attack of fever, at other times not until the end of the fever therapy, and not at all always following the highest temperatures. Another peculiarity is that the herpes blisters usually reappear at the same sites (virus fixation). Regarding the problem of spontaneous contagion the author says that the literature reports no unquestionable cases of contact transmission. He calls attention to the favorable effect exerted by it on other infectious diseases and to the low mortality of pneumonia in patients who develop herpes in the course of the pneumonia and says that similar observations have been made in meningococcal meningitis in complicated female gonorrhea and in malignant diphtheria. He stresses that fever therapy of neurosyphilis is most effective in patients with herpes. Moreover, in some non-herpetic patients with neurosyphilis in whom the first fever therapy had been ineffective he obtained improvement by inoculation with herpes and subsequent activation with fever. Herpetic patients develop neurosyphilis much less often than do patients without herpes. Herpes is more frequent in women than in men, whereas the incidence of tabes and dementia paralytica is comparatively higher in men than in women. Whereas in other disorders the herpes virus seems to influence the disease as such, in the case of syphilis its antagonistic effect involves chiefly the central nervous system.

**Vitamin B<sub>1</sub> in Crural Neuritis**—Hesse observed miners with neuritis of the crural nerve which usually began with severe pains in the lumbosacral region but after several days the pains radiated into the leg. The pains differed from those of sciatica in that they were localized in the flexure of the groin and on the anterior surface of the thigh. The chief complaint is a feeling of weakness in the affected member. Complaints of pains in the knee and on the inner surface of the tibia are also quite frequent. The latter symptoms are manifestations of the irritation of the sensory branches of the crural nerve. That this disorder is especially frequent in miners is probably due to the unfavorable weather conditions that prevail in the mines. In four patients with this form of crural neuritis the author employed the antineuritic vitamin B<sub>1</sub> in addition to the usual physical and medicinal therapy. Every second day 2 cc of vitamin B<sub>1</sub> was injected into the quadriceps of the diseased member. Case reports indicate that the total number of injections varied between six and eight. There were no undesirable secondary effects such as focal reactions or increase in temperature. However the blood pressure often increased by from 10 to 20 mm of mercury. To be sure this increase was only temporary and soon subsided, nevertheless, the author thinks that in view of this increase in blood pressure it is inadvisable to employ the injections of vitamin B<sub>1</sub> in patients who have a considerable hypertension. He suggests that injections of the antineuritic vitamin B<sub>1</sub> should be used also in neuritides of different localization.

\*Congenital Bilateral Flexion Contracture of Thumb in Children. H. Regele—p. 391

**Congenital Flexion Contracture of Thumb**—Regele reproduces the pictures of the hands of two boys aged 3½ years and 8 months, respectively. The two boys had a flexion contracture of the thumb which had been noticed by the parents

soon after birth. The parents had repeatedly attempted to straighten the thumbs. Their efforts were successful but the lasting. Examination of the children disclosed that both were otherwise normal. To counteract the flexion contracture, the thumbs were straightened and an ordinary ampule file was attached to the dorsum by means of adhesive tape and left in this position for four weeks. A few days after that the extension and the flexion of the thumb could be done quite freely. Three years of subsequent observation disclosed that the improvement was permanent. The author says that nothing definite is known regarding the etiology of this defect but he thinks that some obstruction in the region of the flexion tendon and its sheath must be responsible. The suggestion that traumatic or inflammatory processes (rheumatism, gout or tuberculosis) might be a cause could not be accepted for the described cases. The bilaterality and the "congenital" appearance in the otherwise normal children seem to suggest a malformation. It may be that a prolonged intra uterine doubling of the fist may have caused a stenosis of the sheath of the tendon. The success of the treatment of prolonged fixation in extension seems to corroborate the theory of stenosis of the tendon sheath.

Prevention of Varicose Thrombophlebitis. G. Nohl—p. 240  
\*Magnesium Sulfate Poisoning. Case. D. Roller—p. 241

**Cytologic Blood Changes in Cases of Myoma**—Vorlicek and Jelinek, summarizing his observations on the changes in the blood picture of women with myoma and comparing them with the hematologic changes in other gynecologic disturbances, concludes that the myoma as such produces in the majority of cases hematologic changes that may be regarded as specific for this type of tumor. There is an increase in the number of leukocytes and a more or less severe lymphocytosis. The author thinks that, even if from the histologic point of view myomas are benign tumors, it is better to remove them by surgery than to treat them conservatively.

**Poisoning by Magnesium Sulfate**—Roller describes the history of a woman, aged 21, who developed tetany with respiratory disturbances and vertigo following the intravenous injection of 2 cc of a 20 per cent solution of magnesium sulfate. The symptoms were not those that are typical for magnesium sulfate poisoning but were rather due to a calcium deficiency in the serum. The ionic equilibrium had become impaired. The disorder disappeared again following the intravenous injection of calcium. Intravenous injections of concentrated salt solutions should be made slowly.

\*New Investigations on Antianemic Action of Intestinal Mucous Membrane. G. Fros and S. Kunos—p. 270

**Antianemic Action of Intestinal Mucous Membrane**—Eros and Kunos state that, in their opinion, hematopoietic substances are produced not only in the stomach and in the entire intestinal tract but also in other incretory organs and in all organs in which an argentaffin cell system exists similar to that of the gastro intestinal tract. This argentaffin cell system can be influenced by starvation and by various extracts. It is noteworthy that the argentaffin cell system is greatly atrophied in the gastro intestinal tract of patients who have died of pernicious anemia. It is, however, still disputed whether the intestinal juice contains an antianemic factor similar to that of the gastric juice. The authors reasoned that a more effective intestinal preparation might perhaps be produced if the intestine

hens was utilized in which the argentaffin cells had been considerably increased by starvation. Hens were chosen because their intestine has a comparatively large number of argentaffin cells. A number of different extracts were prepared and were tested on rats with Bartonella anemia. The splenectomized rats were given daily subcutaneous injections of from 0.2 to 1 cc of the extract and their erythrocyte count was taken every third day. Tabular reports of the results of these tests indicate that some of the intestinal preparations were entirely ineffective, that one preparation not only reached the efficacy of liver extract but even surpassed it in some respects. This preparation proved effective also by oral administration. In the combined administration of liver and this intestinal extract it was found that a daily dose of 0.2 cc of each was more effective than if either alone was given in a daily dose of 1 cc. The described experiments proved that the extract of the intestinal mucous membrane exerts a favorable influence on the Bartonella anemia of rats. At present clinical experiments are being conducted on human subjects. The results obtained thus far indicate that the preparations of the intestinal mucous membrane which were found efficacious in animals exert a favorable effect on the various forms of secondary anemia but that their action on pernicious anemia is inadequate.

**Mucocoele and Myxoglobulosis of Appendix**—Meyer and Rockstroh direct attention to the rarer disorders of the appendix, the knowledge of which they esteem of considerable practical importance. They report cases of total mucocoele of the vermiform appendix, cases of partial mucocoele in the distal portion of the appendix, a case of partial mucocoele in the proximal portion, a case of myxoglobulosis of the appendix, a case of pseudomyxoma of the peritoneum produced by perforation of a mucocoele in the presence of pseudomucin cystomas of both ovaries, and one case each of pseudomyxoma from the appendix and the ovary. In discussing the pathogenesis of the diverticula and of the mucocoeles of the appendix, the authors point out that the development of the mucocoele presupposes a closure of the lumen in one or several places. As the essential cause, an abnormal production of mucus is assumed. The formation of globoid bodies of mucus results in myxoglobulosis, which is a variety of mucocoele. Pseudomyxoma of the peritoneum is produced frequently by perforation of mucocoele or myxoglobulosis. It is generally denied that this rupture can result merely from the pressure of the contents and from a thinning of the wall and it is believed that inflammation, disturbances in the nutrition and necrosis of the wall are necessary factors. Pseudomyxoma of the peritoneum may be caused also by the perforation of pseudomucin cysts. The prognosis of the latter cases is usually less favorable, because larger quantities of mucus escape. In case of simultaneous existence of pseudomucin cystoma of the ovary and of mucocoele of the appendix, it is difficult to determine which of the two conditions caused pseudomyxoma of the peritoneum. In view of the fact that the majority of pseudomucin cystomas of the ovaries are regarded as endodermal teratomas it is assumed that a constitutional factor is involved in the simultaneous development of pseudomucin cystoma of the ovary and mucocoele of the appendix.

**Development of Deflexion Attitudes**—Jungmann maintains that the mechanism of engagement is determined by the shape of the fetal cranium. The manner of engagement determines whether delivery will take place in normal flexion or in one of the attitudes of deflexion. For this reason the author thinks that the former opinions regarding the origination of these attitudes have to be revised. Studies in ten cases convinced him that the severe deflexions of the head occur in cases in which the cranium is longer particularly in the region of the

occiput. He thinks that deflexion develops because the greater mass of the occiput encounters a greater resistance than the sinciput and thus is prevented from going deeper.

\*Prophylactic Autohemotherapy for Reduction of Postoperative Pulmonary Complications G Karpati—p 516

**Prophylactic Autohemotherapy for Reduction of Postoperative Pulmonary Complications**—Karpati mentions several investigators who have maintained that autohemotherapy surpasses in efficacy all methods ordinarily employed for the prevention of postoperative pulmonary complications. The favorable results obtained by those authors and the realization that theoretically autohemotherapy represents a stimulation as well as an immunologic treatment induced Karpati to try prophylactic autohemotherapy in gynecologic operations done under ether anesthesia. By means of a record syringe that contains 2 cc of a 2 per cent solution of sodium citrate he withdraws 10 cc of blood from the cubital vein of the patient and injects it at once into the extensor musculature of the thigh. With this method he was able to avoid all complications that have been observed after autohemotherapy such as hematuria, hemoglobinuria, chills, nausea, vomiting, headaches, scarlatiniform exanthems and even infiltrations at the site of injection. In order to evaluate the efficacy of autohemotherapy in preventing postoperative pulmonary complications, the author compares the postoperative course of cases in which autohemotherapy was used with those in which it was not used. Summarizing his observations, he states that autohemotherapy did not prevent all postoperative pulmonary complications, nevertheless, the hopes that had been placed in this treatment were realized in that the incidence of the postoperative pulmonary complications as well as the number of fatalities from this cause could be reduced to less than half. However, a single injection of the patient's own blood did not reduce the duration of the pulmonary complications that did develop and the author thinks that such an effect could probably be expected only from repeated injections.

**Kohler-Pellegrini-Stieda Disease**—Pytel defines the Kohler-Pellegrini-Stieda disease as a periarticular posttraumatic ossification developing principally in the tendon of the adductor magnus muscle as a small bony formation producing a peculiar painful symptom complex. He found its shadow in twelve out of 1,316 roentgenograms of cases of traumatic knee joints (0.91 per cent). He reports thirteen cases observed by him in the last five years. The etiologic factor is a relatively mild trauma direct or indirect the latter resulting from an exaggerated adduction. The pathogenesis has been interpreted as the result of a tearing off of a portion of periosteum and bone from the upper aspect of the inner femoral condyle or as an ossification process of the soft periarticular tissues without the participation of the periosteum. The sickle shaped x-ray shadow is formed most frequently within the tendon of the adductor magnus muscle. This shadow becomes apparent in roentgenograms from three to four weeks after the injury. The symptoms are presence of pain within two three or five weeks after injury and tenderness limited to an area of swelling over the inner femoral condyle. Complete flexion and extension of the knee joint cause pain. Exact diagnosis is made on roentgenograms made immediately after the injury and at later periods. Most authors advise conservative therapy. This consists of immobilization, diathermy, ultraviolet irradiation and later, massage,

movement and roentgen irradiation. Operative intervention becomes necessary only after the conservative measures have failed or in the presence of a large bony formation interfering with the function of the joint.

Symptomatology and Treatment of Spinal Cord Tumors. N. Liedberg—p. 452

**Postoperative Progressive Gangrene of Skin**—Liedberg reports a case in which, following an operation for gangrenous appendicitis, there developed on the fifth postoperative day a necrotic gangrenous process about the primarily closed wound. While exhibiting a tendency to epithelization, the necrotizing process slowly but unremittingly advanced in spite of the local measures until at the end of five months it had involved practically all the anterior aspect of the trunk and caused the patient's death. The process was characterized by slow progression, which amounted to no more than 1 cm a week and by only a moderate rise in temperature, moderate anemia and excruciating pain, particularly on manipulation of the wound. The author reviewed forty cases from the literature in which the gangrenous process involved the skin of the abdomen or the thorax. The process seems to constitute a fairly typical clinical entity characterized by slowly advancing gangrene of the skin and the subcutaneous tissue and accompanied by severe pain. Most of the cases developed after an operation with drainage of a suppurative appendicitis. Meleney's studies suggest that the gangrene is the result of a synergistic action on the part of a specific enterogenous streptococcus with staphylococci. The only effective treatment is radical excision of the margins of the wound with a diathermy knife.

**Head Injuries and Temporal Bone Involvement**—Skoog analyzes 794 injuries of the skull treated at the Surgical University Clinic of Lund, Sweden, between 1924 and 1933. Of these, 370 had a verified fracture. The author deals in detail with fractures involving the temporal bone. The diagnosis of a fracture of the temporal bone is aided by roentgen rays far more now than was formerly the case. The percentage of clinically certain or suspected cases of fracture in which the roentgen observation was negative was extremely low in 1933 as compared with conditions in 1924. The surest diagnosis, however, is furnished by the anatomic and functional otologic examination. In 389 per cent of the cases of fracture an involvement of the temporal bone and the auditory organ could be established. The different types of temporal bone fractures are discussed in detail with reference to their symptomatology and prognosis. The therapeutic measures in uncomplicated cases run in a strictly conservative direction, stressing careful observation of the cerebrospinal fluid. Operation is recommended at the slightest indication of incipient meningitis. It consists of chiseling of the mastoid process and exposure of the dura. The radical operation should be resorted to only in exceptional cases. Ninety-four fractures of the temporal bone comprising ninety pyramidolongitudinal fractures and four pyramidotransverse fractures, have been the object of a closer functional otologic examination. The four clinically suspected pyramidotransverse fractures exhibited a loss of the cochlear and vestibular functions. Three exhibited a spontaneous nystagmus toward the unaffected side, and in the fourth the nystagmus was not definite but roentgen study suggested that the fracture involved the labyrinth. Facial palsy occurred in only one of the cases and showed some tendency to improvement during hospitalization. The ninety pyramidolongitudinal fractures showed with two exceptions, auditory disturbances of the middle ear as well as of the internal ear, though chiefly of the former, and vestibular disturbances in 433 per cent. Involvement of the temporal bone does not seem to entail an increased predisposition to disturbances within the vestibular area as compared with fractures of other localization or in cranial trauma without fracture.

Comparative Investigations on Relations of Serum Cholesterol in Normal Persons and in Manic Depressive Patients After Administration of Cholesterol in Olive Oil and After Administration of Olive Oil. G. Brun—p. 57

**Problems Concerning Dementia Praecox**—Smith states that, while there may be a slight preponderance in the occurrence of psychoses of the same subgroup in a given family, the different subgroups appear in near relatives, suggesting a close connection. The psychoses in the dementia simplex and catatonia groups occur on the average earlier in the patient's life than do the psychoses in the dementia paranoides group. Dementia simplex is more frequent in men, while dementia paranoides occurs oftener in women. The changes in the spinal fluid are noticeably greater in the dementia simplex and catatonia groups. The changes in the blood picture are alike in the three groups. The patients having dementia paranoides show more tendency to pyknoform physical types. The author is inclined to consider dementia praecox a hereditary entity, the difference in the phenotype of the subgroups being as a rule due not to a special tendency but to the constitution, the same tendency causing early or late and more or less deleterious psychoses, the most marked cases appearing in the leptiform types and the pyknoform offering more resistance. The more pronounced changes in the spinal fluid in dementia simplex and catatonia might perhaps be considered an expression of the greater organic changes in these two groups.

- \*Morgagni's Syndrome (Internal Frontal Hyperostosis. Virilism Obesity). F. Henschen—p. 65

**Morgagni's Syndrome**—Henschen says that internal frontal hyperostosis, apparently considered relatively rare in the literature, was present in sixty-six, or about 40 per cent, of 160 skulls of women aged 47 or more. Except for one atypical case in a man, the condition was seen in his material only in women, and not in women less than 47. In the literature seven or eight cases of changes closely resembling frontal hyperostosis in women have been reported in men. A few cases are described in younger women, as in a woman aged 40 presenting acromegaly, in an epileptic patient aged 37 having juvenile dementia, and in a woman aged 34 having adiposogenital dystrophy. The development of this feminine anomaly is apparently related to the change which the feminine organs undergo in connection with the climacterium. The physical constitution often shifts toward the masculine, in some cases of acromegaly, changes or of marked acromegaly together with obesity, disturbances in the function of the pituitary are suggested. The site of the development is ascribed to "local disposition." Morgagni's syndrome, the author emphasizes, is a slightly abnormal variant of the change that normally occurs in the feminine endocrine status after the menopause and gives no clinical symptoms. Internal frontal hyperostosis is also of interest from the point of view of paleopathology, constituting an inconstant sexual characteristic which may be significant in the determination of age and sex in skull fragments.

## BILATERAL GANGRENE OF FEET DUE TO ERGOTAMINE TARTRATE USED FOR PRURITUS OF JAUNDICE

REPORT OF A CASE STUDIED ARTERIOGRAPHICALLY  
AND PATHOLOGICALLY

WALLACE M YATER, M D

JAMES A CAHILL, M D

WASHINGTON, D C

Ergot is one of the most efficacious and commonly used drugs. Ergot itself (*Claviceps purpurea*), a fungus which grows on rye and certain grasses, is a variable mixture of various potent and relatively inert substances. The main active constituents are the alkaloids ergotoxine and ergotamine, and the amines histamine and tyramine. Before the isolation of crystalline ergotamine, the official fluid extract of ergot was the preparation mainly employed. According to Rothlin,<sup>1</sup> Nelson and Pittee<sup>2</sup> and others the alkaloid ergotamine is the most important constituent of ergot and the one the presence of which in ergot preparations should be ensured. Since the isolation of ergotamine ( $C_{33}H_{45}O_5N$ ) by Stoll and Spiro in 1921 this alkaloid has come to be extensively used mainly as the tartrate.<sup>3</sup> Its most important uses have been the prevention and control of postpartum hemorrhage from atonic uterus, and the treatment of retained lochia delayed involution bleeding following cesarean section, and hemorrhage from abortion. It has recently been advocated by various authors for the treatment of many other conditions, however, among which are migraine, exophthalmic goiter, pulmonary hemorrhage, pruritus, diabetes mellitus, diabetes insipidus, melancholia, prolapse of the rectum, and glaucoma. However, for years the Council on Pharmacy and Chemistry has given warning about the possibility of ergotism from the use of this drug.

Ergot consumed in bread made principally of rye has been known for centuries to cause epidemics in Europe of ergotism, or chronic poisoning due to ergot. There are two forms of ergotism: the gangrenous and the convulsive. Sometimes only the gangrenous form occurred in the epidemic, at other times only the convulsive, while occasionally the two forms occurred in the same epidemic.<sup>4</sup> The convulsive form which does

not produce such highly characteristic effects as the gangrenous has not received the same historical recognition as the latter.<sup>5</sup> The existence of the two forms is probably due to the presence of variable quantities of two or more poisonous principles in the spur. The exact pathogenesis of the convulsive form is not known.

The excellent researches of Dale<sup>6</sup> in 1906 on the physiologic actions of ergot have stood the test of time. Dale and his co-workers and others have extended the work to include the actions of the various more recently isolated constituents of ergot. Dale stated in 1906 that "the first definite laboratory demonstration of the stimulant effect of ergot on the peripheral arteries was given by Kobert. The gangrenous phenomena that he observed in the comb and other peripheral structures of the fowl and the pig as the result of administering sphacelmic acid, were attributed by von Recklinghausen, who investigated the phenomena histologically, to powerful and persistent constriction of the arterioles." Dale's main conclusions from his experiments on animals were as follows:

1 The physiological effects of preparations from ergot such as cornutine and sphacelotoxin fall naturally into two groups: (a) Stimulant effects on plain muscular organs prominent among which are contraction of the arteries, the uterus and the sphincter of the iris. (b) A specific paralysis of the motor elements in the structures associated with sympathetic innervation which adrenalin stimulates, the inhibitor elements retaining their normal function as do also both motor and inhibitor autonomic nerve supplies of cranial and sacral root origin.

2 It is probable that these two sets of effects are produced by different active principles of which the one responsible for the peripheral paralysis appears also to be concerned in the central convulsant effects described by Kobert and others.

According to Cushny,<sup>7</sup> "the study of the alkaloids of ergot, ergotamine and ergotoxine, in the living organism has shown that they resemble epinephrine in some of their effects and like it act on the myoneurial junctions of the true sympathetic nerves. But while epinephrine stimulates these junctions indiscriminately whether they are motor or inhibitory in character the ergot alkaloids do not act on the inhibitory junctions at all and while stimulating the motor myoneurial junctions in small doses, paralyze them in large amounts. They are less powerful than epinephrine but the effects last longer and can be elicited by hypodermic injection or even by administration by the mouth.

The secondary paralyzing action of ergotamine on the myoneurial junctions is elicited only by large doses and does not occur in the therapeutic use of ergot." There has been much discussion by physiologists and pharmacologists with regard to the dual action of ergotamine both

in constricting and in dilating the vessels. Whatever may be the answer to this knotty problem, from the practical clinical point of view it is mainly the constrictor action that causes concern.

Cases of gangrene or threatened gangrene of the extremities due wholly or partly to the therapeutic use of ergotamine tartrate while not numerous have been sufficiently conspicuous to give pause for thought. Most of these cases have concerned women with puerperal fever. Carreras<sup>8</sup> described a fatal case in which a woman with severe puerperal fever after a total oral dosage of 0.0265 Gm of ergotamine tartrate in one week developed excitement, formation vomiting, diarrhea, sweating, weak pulse, muscle contractures, fixed miosis and gangrene of the feet. Antoine<sup>9</sup> reported a case in which a woman with severe puerperal fever after a total dosage of 0.05425 Gm of ergotamine tartrate developed bilateral gangrene of the legs. There was thrombosis of all the veins of the amputated limbs and spasm of the arteries. He described a similar case of gangrene of one leg following the use of 5 cc of stabilized ergot. In neither case did he regard the ergot preparation as the sole cause of the gangrene but only as a sensitizing factor.

Guggisberg<sup>10</sup> was of the same opinion. He reviewed ten cases of gangrene following labor at term or mis-

esses. He called attention to the fact that the literature contains a large number of reports of puerperal gangrene associated with puerperal infection in which ergot preparations were not used. He concluded that the most common causes of such accidents are emboli and thrombosis occluding peripheral vessels. In his opinion the gangrene is due not to vascular spasm but possibly to the action of some toxin on the vessels and tissues producing peripheral vascular stasis. He warned, however, against the use of ergot preparations in febrile puerperal patients.

Saenger<sup>11</sup> reviewed the literature dealing with gangrene in the puerperium or following miscarriage which had been attributed to ergotamine tartrate. He found fourteen cases reported. In seven there was gangrene of both feet, in four gangrene of one leg or foot in one gangrene of some of the fingers of one hand in one gangrene of the uterus and of the right leg, and in one gangrene of the uterus. Practically complete recovery without amputation occurred in six cases. The range of total dosage was from 65 to 117 mg of ergotamine tartrate. In no case was there a normal labor or puerperium. In nine cases there was puerperal fever and in four cases febrile abortion. In a few also the history suggested pre-existing functional vascular disease. In all cases the possibility existed of septic vascular damage and the ergotamine tartrate was assumed by Saenger to be merely an additional malefactor. In some of the amputated limbs, thrombi in veins and contracted arteries were found. In his discussion he called attention to the eighty cases of peripheral puerperal gangrene collected by Wormser<sup>12</sup> and the large number of cases collected by Stein<sup>13</sup> in the great majority of which the lower limbs were affected and in which ergot preparations did not play a role. Ellerbroek<sup>14</sup> came to a conclusion similar to Saenger's in his three cases of gangrene in women with an abnormal puerperium in these cases the gangrene affected sites other than the distal parts of the extremities.

The case of Oginz<sup>15</sup> is interesting. A primiparous patient, aged 19, developed evidence of severe infection after a normal labor. An injection of 1 cc of ergotamine tartrate was given every four hours, so that a total of 45 cc (0.0225 Gm) was given within two weeks. Fluidextract of ergot to the extent of 6 drachms (22.5 cc) also was given during this time. One week after labor the upper and lower extremities became cold and cyanotic, and disappearance of the radial pulses soon followed. Two days later severe pain and numbness began in the toes. Later the fingers became very painful and tingled. The right foot became very cyanotic, the left heel very discolored. Ergotamine tartrate was given for several days after these symptoms appeared, but twenty-four hours after its use was discontinued and local treatment instituted rapid improvement began, the radial pulses returning in good quality. The left foot improved faster than the right. The final result was that three toes of the right foot were lost after ten weeks by amputation, and later a metatarsal bone was removed surgically. The puerperal infection had subsided during the period of recovery of the extremities. This case is fairly illustrative of the cases in which nearly complete recovery from ergotism

While it is true that many cases of gangrene do occur in patients with severe puerperal infection to whom little or no ergot has been given and that practically all the cases of gangrene in which ergot has been implicated have been complicated by puerperal infection, nevertheless the conclusion cannot be escaped that the ergot played a very important role in many of them, as illustrated so well by Oginz's case.

Fig. 3.—Cross section of the right anterior tibial artery at about the middle of the occluded portion. There is marked constriction with concentric infolding and hyaline degeneration especially of the intima. Van Gieson's connective tissue stain.  $\times 23$ .

ensues. Schmidt's<sup>16</sup> case was almost identical but no parts were lost. Roch's<sup>1</sup> case was quite similar, partial amputation of one foot eventually becoming necessary.

Fig. 4.—Cross section of the right posterior tibial artery near its lower end, with its venae comitantes. The artery is greatly constricted with infolding of a sector of the wall. The veins are moderately collapsed. The elastic laminae are shown as black wavy lines. Stained with acid orcein.  $\times 19$ .

Gangrene of the extremities has also followed the use of ergotamine tartrate for exophthalmic goiter. Speck<sup>18</sup> reported the occurrence of impending gangrene of both feet and legs, which became painful, cold, anesthetic and white with bluish mottling following a total dosage of 186 mg of ergotamine tartrate (186 tablets) given in two courses with a break of three weeks in the treatment. Also the right arm was painful. Slow recovery ensued with some residual gangrene of a little toe and an area on the dorsum of the foot. Speck attributed recovery to the use of theophylline. Platt<sup>19</sup> reported a similar case of gangrene of the feet with slow recovery. He attributed recovery partly to the use of scopolamine. Muller<sup>20</sup> observed a case of bilateral impending gangrene of the feet and legs after the injection of 24 cc of ergotamine tartrate with eventual loss of all the toes of one foot. Milder cases have been reported in which there were severe pains along the course of the arteries without evidence of much circulatory disturbance. The results of the treat-

ment of exophthalmic goiter with ergotamine tartrate are certainly not sufficiently encouraging to warrant continuance of this form of therapy.

Besides gangrene, which is the most important toxic disturbance due to ergotamine tartrate, other toxic manifestations have been observed. The commonest are headache, nausea, vomiting, diarrhea and dizziness. Less common symptoms are weakness, foimication and

chill, which was repeated daily. There were generalized muscular aching, malaise and thirst. The family history was irrelevant. The past history was negative except for chronic constipation, hemorrhoids, the "corn itch," and some dysuria and nocturia. The patient was thin but muscular with apathetic facies, a low order of intelligence and moderate jaundice with scattered petechiae of the arms, thorax and abdomen. He was cooperative but somewhat confused. The pupils were moderately constricted. There was evidence of poor dental hygiene and the tongue was coated. The heart and lungs were apparently normal. The heart rate was 80 per minute with regular rhythm and respiration was normal. The blood pressure was 110 systolic and 80 diastolic. Moderate tenderness and rigidity were present in the right upper quadrant of the abdomen and slight tenderness was noted in the right costovertebral angle. The prostate gland was moderately hypertrophied as determined by digital rectal examination. The extremities were apparently quite normal. The deep tendon reflexes were equal but moderately reduced in intensity. The temperature was 98.6 F. Urinalysis showed a trace of albumin. A hemogram showed 83 per cent hemoglobin (Newcomer method), 4,270,000 erythrocytes and 9,650 leukocytes per cubic millimeter of blood, with 64 per cent polymorphonuclear neutrophils, 12 per cent eosinophils, 1 per cent mast cells, 20 per cent small lymphocytes and 3 per cent monocytes. The Wassermann and Kahn reactions of the blood were negative. The

Fig 5—Cross section of the left posterior tibial artery, near its lower end with its venae comitantes. itching, coldness of the skin, thirst, confusion, depression, drowsiness, cyanosis, syncope, collapse, anginal pains, tachycardia or bradycardia, elevation or lowering of the blood pressure, amblyopia, cataract, twitching, muscular cramps, convulsions, hemiplegia, tabetic symptoms and sudden death. Labbe, Boulin, Justin-Besançon and Gouyen<sup>21</sup> described a case of hyperthyroidism, treated with ergotamine tartrate, in which there were severe anginal pains, hemiplegia and jacksonian epilepsy. Only 1.5 mg of the drug was administered. Another patient of theirs vomited, became comatose and died in five hours after the administration of only 0.5 mg of the drug. Panter's<sup>22</sup> hyperthyroid patient developed miosis with fixed pupils and absence of the deep reflexes following the injection of 5 mg of ergotamine tartrate in three days. These manifestations disappeared within eighteen days. Kravitz<sup>23</sup> reported a case of optic atrophy secondary to neuroretinitis, apparently produced by pills containing ergot taken because of amenorrhea.

#### REPORT OF CASE

**Clinical History.**—An unmarried white man, aged 64, a fisherman, admitted to the Georgetown University Hospital Aug 1 1935, had spent much time wading in shallow water to obtain live bait. His illness had begun a week before with a severe

Fig 6—Cross section of the left anterior tibial artery near the upper end of the occluded portion. It is extremely constricted, the lumen being slitlike. There is moderate atherosclerosis. Hematoxylin and eosin stain.  $\times 28$ .

qualitative van den Bergh reaction was direct in thirty seconds and the quantitative test showed 13.6 mg of bilirubin per hundred cubic centimeters of blood.

The day after admission the patient began to complain of severe generalized pruritus. For this, 1 cc of ergotamine tartrate (0.0005 Gm) was ordered by a resident to be given by hypodermic injection three times daily, although the usual method of administration in this hospital had been oral. It was administered for six and one-third days a total of 0.0092

<sup>21</sup> Labbe M, Boulin R, Justin-Besançon L and Gouyen J. Angine de poitrine ergotaminique. *Press med* 37: 1069 (Aug 17) 1929.

Gm of ergotamine tartrate being given<sup>24</sup> On the second day of the administration of ergotamine tartrate there was coldness of the upper extremities which was not later complained of On the third day there was tenderness of the long bones of the legs On the fourth day there was a subjective burning sensation in the toes of the left foot, and coldness and blueness of the distal one third of both feet were noted The left dorsalis pedis artery was palpable but not the right The blood pressure on this day was 138 systolic and 120 diastolic On the fifth day

Fig 7—Higher magnification of a sector of the wall of the artery shown in figure 3 The hyaline degeneration is better shown There are nuclei probably of connective tissue cells mainly in the infolded portion Van Gieson's connective tissue stain  $\times 153$

the legs and feet were very painful the first three toes of the left foot and the first two of the right were purplish red and pulsations could not be felt in the vessels of either foot On the sixth day both feet were painful cold and blue, but faint pulsations were palpable in the dorsalis pedis arteries

At this time the ischemia of the feet was not associated by the visiting physician with the use of ergotamine tartrate, which he was not informed was being given, but the next day the use of this drug was stopped by the resident who had ordered it because the pruritus had ceased The feet continued to be very painful, the pulsations of the arteries of the feet ceased entirely and the skin of the feet remained cold and mottled with blue On the thirteenth day after the beginning of administration of ergotamine tartrate the toes of both feet began to turn black and to become dry and shriveled with a definite line of demarcation The feet had continued to be very painful The pulsations of the popliteal arteries were strong The blood pressure in the arms was 110 systolic and 70 diastolic, and in the thighs it was 155 systolic and 90 diastolic At this time the diagnosis of probable ergot poisoning was made although the medical consultant was not informed of the fact that ergotamine tartrate had been used Amputa-

tion of both feet at the junction of the middle and lower thirds of the legs was recommended by the surgical consultant

During the month in which the gangrene of the feet had been developing the patient had improved greatly otherwise He slowly became clear mentally the jaundice disappeared, and the abdominal tenderness and rigidity subsided During the first ten days the temperature rarely went above 99.5 F but after this it was almost continuously irregularly elevated ranging from 98.6 to 104.2 F but usually between 100 and 102 F The pulse rate ranged usually between 90 and 100 per minute Because of dehydration and jaundice 5 per cent dextrose solution was given intravenously in amounts of from 1 to 3 liters daily Other symptomatic and supportive measures of therapy were employed

September 13 just forty days after the first dose of ergotamine tartrate had been given the right leg was amputated about half way between the knee and the ankle By this time mild infection was evident in both feet at the line of demarcation of the gangrene (fig 1) At the time of operation an arteriogram was made by means of injection of 15 cc of thorium dioxide sol into the right popliteal artery (fig 2) This showed the main arteries of the leg to be smooth in outline and apparently normal down to the lower third of the leg where they faded out into a point small long and somewhat tortuous collateral arteries passed downward toward the feet from the arteries above the point of occlusion So far as we know, these are the first arteriograms ever made from the human subject in a case of gangrene due to ergot September 16 the left foot was amputated below the ankle Following these operations the fever continued as before and because of moderate anemia blood transfusions were given The stump of the right leg healed normally that of the left, however became necrotic and on September 26 the left leg was amputated about half way below the knee This new stump healed normally

Fig 8—Cross section of a small artery in the foot proximal to the gangrenous area The vessel is moderately constricted and the intima appears to be proliferated Stained with acid orcein  $\times 97$

By September 30 the temperature had returned to normal and it remained so November 4 the patient left the hospital in good general condition with the stumps of both legs healed

**Examination of the Amputated Extremities**—Both feet showed typical dry gangrene with moderate secondary infection and a line of demarcation at the distal third (fig 1) When the vessels of the amputated legs were dissected out all showed grossly similar changes They all appeared to be constricted

<sup>24</sup> Lichtman (Therapeutic Response to Ergotamine Tartrate in Pruritus of Hepatic and Renal Origin) *J A M A* 97:1463 (Nov 14) 1931 and Snell and Keyes (Pruritus of Jaundiced Patients: Its Incidence and Treatment) *Clin North America* 16:1455 (Nov) 1931 reported excellent results with ergotamine tartrate in cases of pruritus due to jaundice They used 1 mg orally three or four times daily Snell and Keyes suggested that if used subcutaneously or intramuscularly doses of from 0.5 to 1 mg be used once daily

throughout their course. The degree of constriction varied, however, at different points. In some sections the vessels were so severely constricted that their lumens were almost obscured. In other sections they were less severely constricted, and in these areas the lumens were filled with thrombi. The veins were all practically empty.

Microscopic sections of all the arteries frequently including their venae comitantes were made and various stains were employed (hematoxylin and eosin, van Gieson's connective tissue stain, Masson's trichrome stain, Verhoeff's elastic tissue stain and acid orcein). The sections of the larger arteries confirmed the gross appearance of these vessels. Depending on the degree of constriction of the artery, the wall appeared to be thickened. The greater the degree of constriction the greater was the apparent thickening. The constriction took various forms. In some sections the intima was thrown into concentric folds which projected into the lumen, almost completely filling it (fig. 3). In others there was eccentric infolding with one sector of the wall bulging deeply into the lumen (fig. 4). In still other sections there was only moderate and irregular concentric infolding with the lumen fairly well preserved and filled with a thrombus undergoing organization (fig. 5). At some points where the constriction was great the lumen on cross section was slitlike, apparently because of the presence at these points of moderate atherosclerosis (fig. 6).

The thrombi were all in the less constricted segments. The venae comitantes were usually empty or contained apparently liquid blood. They seemed to be moderately constricted or collapsed and their walls also appeared to be thickened. There was no evidence of inflammation in or about the walls of any of the vessels except in the gangrenous portions of the feet. The walls of all the vessels, more particularly the arteries, were in the process of hyaline degeneration (fig. 7). Both the media and the intima were thus affected. The more constricted the vessel the thicker and more dense and homogeneous was the intima. The hyaline substance had separated and partially replaced the muscle fibers of the media. Into the intimal folds the media appeared to be streaming, but in these portions of the wall hyaline changes were advanced and nuclei apparently of connective tissue cells were present in moderate numbers. The internal and external elastic laminae were fairly well preserved, although the internal lamina was broken in places in the most severely constricted segments and the external lamina was considerably fragmented although rather compact. The small arteries and arterioles showed changes very similar to those of the arteries but while they were constricted the intima was not usually thrown into folds and thrombi were rarely seen.

In the feet just proximal to the gangrenous area some of the small arteries showed changes very suggestive of proliferation of the intima (fig. 8) in some instances the lumen being almost completely obliterated by the cells. Within the gangrenous area the walls of the small arteries and veins showed various degrees of secondary inflammatory reaction and a few small veins contained thrombi. One medium sized nerve showed vacuolization of the myelin sheaths. There was astonishingly little evidence of arteriosclerosis.

#### COMMENT

Since the study of von Recklinghausen<sup>25</sup> long ago of the histologic changes that occur in the cock's comb in ergotism little has been added to his description. Others have confirmed his observations. Recently Lewis<sup>26</sup> with the collaboration of Gelfand has carried out histologic researches on the gangrene of the comb of white Leghorn hens due to daily injections of 10 mg. of ergotamine into the breast muscles. From the study these workers concluded that the "vascular spasm in ergot poisoning does not arrest the circulation and so does not cause gangrene directly. The spasm profoundly slows the blood stream and leads to the secondary changes in the vessels described" (thrombi due

to stasis from injury to the endothelium and loss of plasma). This idea is strengthened by the results in our case, although the degree of constriction alone seemed sufficient to be productive of serious ischemia.

The fundamental pathogenesis of the gangrene, as demonstrated by our case, is certainly intense constriction of the arteries and arterioles with thrombosis completing the vascular occlusion. The hyaline change are undoubtedly secondary to nutritional deficiency of the walls of the vessels due to occlusion of the *vasa vasorum* by the constriction of the vessels.

Kaunitz,<sup>27</sup> on the basis of experiments similar to those of Lewis and because of certain etiologic resemblances, has postulated the possible implication of ergot in the causation of thrombo-angitis obliterans. The suggestion is interesting but proof is certainly lacking although there is pathologically a superficial resemblance between the two conditions. More recently McGrath<sup>28</sup> has called attention to the pathologic similarity and has reemphasized the fact that in epidemics of gangrenous ergot poisoning the male has been the more predominant victim, just as he is of Buerger's disease. He found the predominant histopathologic features of the gangrenous tails of poisoned rats to be marked cellular proliferation and swelling of the intima, especially in the smaller arteries and arterioles, and organizing thrombi in the arteries. The proliferation of the intima of some of the small arteries and arterioles has been referred to in our case. McGrath showed that although gangrene could be produced in both males and females, the females were completely protected by the use of sufficiently large daily doses of theelin, while the male rats were incompletely protected. The inference is that in the case both of ergot poisoning and of thrombo-angitis obliterans the female may be protected by a sex hormone, probably the estrogenic substance of the ovary.

Ergotamine tartrate is such a useful drug, especially when properly employed by obstetricians that it should not be condemned because of occasional cases of gangrene or other poisonous effects. Certain precautions should be observed, however. A study of the literature leads definitely to the conclusion that great hesitancy should be employed in its use in the febrile puerperium. Probably also the drug should not be administered to patients, male or female, with any acute infectious or toxic disorder. A history of vascular disease, whether functional or organic, would appear also to constitute a contraindication. Our patient was suffering from toxemia of unknown cause, and possibly his occupation, which involved frequent wading in water, may have predisposed the vasomotor innervation of the arteries of his legs and feet to increased susceptibility to toxins.

Some authors advocate a small test dose of the drug to determine whether increased susceptibility exists. Others suggest using the drug orally only. Neither of these precautions is sufficient for the avoidance of toxic effects. It seems to us that, when patients with the contraindications mentioned have been eliminated, the important precautions are the avoidance of prolonged use of the drug and careful watch for the appearance of toxic manifestations, including frequent observation of the hands and feet.

At the slightest indication of a toxic effect, whether systemic in nature or local, use of the drug should be

<sup>25</sup> von Recklinghausen. *Handbuch der allgemeinen Pathologie*. Stuttgart 1883.

<sup>26</sup> Lewis, T. The Manner in Which Necrosis Arises in the Fowl's Comb Under Ergot Poisoning. *Clin. Sc.* 2: 43 (Sept.) 1933.

<sup>27</sup> Kaunitz, J. The Pathological Similarity of Thrombo-Angitis Obliterans and Endemic Ergotism. *Am. J. Path.* 6: 299 (May) 1930.

<sup>28</sup> McGrath, E. J. G. Experimental Peripheral Gangrene. Effect of Estrogenic Substance and Its Relation to Thrombo-Angitis Obliterans. *Arch. Int. Med.* 55: 942 (June) 1935.

discontinued. Measures to produce vasodilatation should be instituted immediately on the appearance of evidence of disturbed peripheral circulation. Polak<sup>29</sup> found that in experimental gangrene the administration of epinephrine markedly delayed the gangrenous process. Possibly this drug would be of value in clinical cases. Some other strongly vasodilating drug, such as papaverine hydrochloride, might also be tried. Mild local heat should be carefully applied. The value of passive vascular exercises induced by alternating positive and negative pressures is questionable, but this method of treatment deserves a trial.

#### SUMMARY AND CONCLUSIONS

1 Ergotamine tartrate, an efficacious alkaloid of ergot, is capable of producing serious toxic disturbances usually as a result of overdosage. Chief among these ill effects is gangrene of the extremities.

2 The cause of the gangrene is occlusion of the medium sized and small arteries and arterioles by severe constriction and thrombosis. Intimal proliferation of small arteries may also play a rôle. Hyaline degeneration of the vessels follows the vasoconstriction.

3 The drug probably should not be used in cases of febrile puerperium, in cases of severe toxemia from any cause or in patients who have presented evidence of vascular disease, functional or organic.

4 Except when well established indications for its use arise, the drug should not be employed except by careful investigators who are able to observe constantly their patients.

5 At the present time use of the drug probably should be limited by the profession at large to appropriate obstetric and gynecologic conditions and to the relief of migraine. Taken orally, the drug is less apt to produce toxic effects than when it is injected.

6 When the drug is used, careful watch should be kept for the appearance of any toxic symptoms, including signs of impaired peripheral circulation. On the appearance of these, the use of the drug should be discontinued immediately. Epinephrine and papaverine hydrochloride are suggested for relieving the vascular spasm.

7 In the case here reported a fisherman had a toxemia with jaundice of unknown etiology. Ergotamine tartrate was injected because of pruritus. Within a week 19 cc was used. Gangrene of the feet developed during this time, and amputation of the legs was necessary. Study of the vessels showed the changes due to ergotism. This is apparently the first case of gangrene of the feet due to an ergot preparation in which autograms have been made.

8 The total dosage of ergotamine tartrate administered in this case was larger than should have been employed by hypodermic injection. The only excuse is that the medical resident who ordered the drug was not sufficiently informed concerning its use. Others may be equally uninformed. The attending physician did not know the drug was being used.

9 Not only the Council on Pharmacy and Chemistry of the American Medical Association<sup>30</sup> but also the manufacturers of the material used have repeatedly warned against the dangers of overdosage and prolonged use of the drug.

Georgetown University Hospital

## GANGRENE AND DEATH FOLLOWING ERGOTAMINE TARTRATE (GYN- ERGEN) THERAPY

S E GOULD MD  
ALVIN E PRICE MD

AND  
HAROLD I GINSBERG MD  
ELOISE NICH

In view of the recent increasing use of ergotamine tartrate (gynergen) in clinical medicine the following case report suggesting some of its possible dangers may be of interest.

#### REPORT OF CASE

*History*—M I, a white woman, aged 52 a housewife was admitted to the Medical Service of the William J. Seymour Hospital Sept 5 1935. Her chief complaints were hematuria, urgency of urination and weakness. Her present illness began

Fig 1—Arterioles, venules and capillaries of epicardium.  $\times 90$

four weeks before admission at which time in a suicidal attempt the patient swallowed 200 grains (13 Gm) of barbital. She was taken to the Detroit Receiving Hospital where she remained for four weeks. During this period she developed hematuria and urgency of urination but these symptoms disappeared soon after her admission to this hospital. The weakness was of two years duration and was associated with numbness and tingling of her upper and lower extremities. Her past history was negative except for a weight loss of 40 pounds (18 Kg) during the past three years, an appendectomy and a right oophorectomy in 1917 and a left oophorectomy and a hysterectomy in 1927.

*Examination*—The patient was apathetic and not much ill. The skin was pale and very dry. The hair was coarse and

From the Department of Pathology of Wayne University College of Medicine, Detroit, and the Departments of Pathology and Medicine of the William J. Seymour Hospital, Eloise, Mich.

<sup>29</sup> Polak E. Experiments on Ergotism. *Casop lek* 63:1409 (Sept.) 1924.

<sup>30</sup> Council on Pharmacy and Chemistry. New and Nonofficial Remedies. Chicago: American Medical Association, 1935, p. 210.

dry with marked thinning. Fundoscopic examination revealed a moderate degree of sclerosis of the vessels. The examination of the heart, lungs, abdomen and pelvis was negative. The blood pressure was 105 systolic, 75 diastolic.

Laboratory examination on admission revealed: Urine specific gravity 1.006, albumin ++, sugar negative, and from 10 to 15 white blood cells. Blood count: hemoglobin 9.2 Gm.,

Fig 2—Right femoral artery  $\times 25$

red blood cells 3,460,000, white blood cells 11,800, polymorphonuclears 60 per cent (filamented forms 57, nonfilamented 3), lymphocytes 35 per cent, mononuclears 5 per cent. Gastric analysis was normal except for the presence of red blood cells. Blood Kahn and Kline reactions were both negative. The basal metabolic rate was minus 40 and minus 36 per cent.

**Clinical Course**—The clinical impression was hypothyroidism. The patient was given thyroxin and later thyroid extract under which medication she showed a persistent progressive improvement in both her physical and mental condition and her basal metabolic rate was raised to within normal limits. Her subsequent course in the hospital was uneventful until November 13, when she complained of pain in both hands. The metacarpophalangeal joints were tender. A roentgenographic examination revealed no evidence of bone erosion or loss of joint space. It was believed that the patient was developing an early atrophic arthritis for which she was given injections of neoarsphenamine. December 3 she received 0.15 Gm of neoarsphenamine intravenously and thereafter 0.3 Gm every fourth day for five injections. December 18 the sclerae developed an icteric tint. The liver was not palpable. On the following day there was diffuse icterus. Neoarsphenamine therapy was discontinued, the patient was given sodium thio sulphate and dextrose intravenously and placed on a high carbohydrate and high calcium diet. December 20 the blood showed an icterus index of 66, an immediate direct van den Bergh reaction and a serum bilirubin of 15 mg per hundred cubic centimeters of serum. It was believed that the patient had developed toxic liver damage secondary to the neoarsphenamine. December 24 there was a slight trace of urobilinogen in the urine. The serum bilirubin was 25 mg per

hundred cubic centimeters. December 30 albuminuria was ++++. The icterus index rose progressively. X-ray studies showed no evidence of disease of the gallbladder, esophagus, stomach or duodenum. Because of pruritus the patient was given an ampule of 0.5 cc 1:2,000 (0.25 mg) ergotamine tartrate (Gynergen) subcutaneously December 28 and thereafter one ampule daily up to and including December 31, receiving a total of four ampules (1 mg). On December 29 following the second injection, the patient began to complain of pain and coldness in her legs. Her temperature was 100.5 F. December 30, examination disclosed cyanosis, coldness and impaired sensation of the lower two thirds of both legs. A light cradle was placed over her lower extremities. On the morning of December 31 there was definite bluish mottling of the lower two thirds of both legs. Both hands were cold and cyanotic. Pulsation of the dorsalis pedis and radial arteries could not be felt, nor was a blood pressure reading obtainable. Pulsation of the posterior tibial and popliteal arteries was barely palpable. The heart sounds were regular and of fair quality. Examination of the fundi revealed definite narrowing of the arteries with arteriovenous compression which was not present when she was examined on admittance. Gynergen was now suspected of being the cause of the gangrene. Surgical consultation recommended conservative measures. Accordingly the patient was given vasodilators consisting of glyceryl trinitrate and amyl nitrite, along with strychnine sulfate. Passive vascular exercise was attempted but could not be continued because of mechanical difficulties. The appearance of the upper extremities improved. The legs, however, became progressively more involved until there was blackness of the lower two thirds

Fig 3—Arteriole and capillary pancreas  $\times 200$

with maceration of the skin. Despite the administration of amyl nitrite and glyceryl trinitrate no definite dilatation of the vessels in the fundi could be demonstrated. The patient's general condition became progressively worse. She became semistuporous and dyspneic and died Jan 1, 1936, at 3 p.m. Terminally there was a temperature elevation to 101.4 F.

**Autopsy**—This was performed one hour after death (H I G). The body was emaciated and markedly jaundiced.

There was a symmetrical, dry gangrene of the lower two thirds of both legs, with some maceration of the overlying skin. Both hands were cyanotic. The thyroid was markedly atrophic. The heart weighed 240 Gm and was of normal color. The coronary arteries and their branches were definitely narrowed. The wall of the aorta appeared somewhat thickened and bile stained. There was atherosclerosis with incomplete thrombosis

Fig 4—Lung arteriole  $\times 135$

of the right femoral artery just above the level of the knee. No other peripheral vessels were removed. The trachea contained some grayish mucoid material. The mucosa was not inflamed. The left lung weighed 240 Gm and showed evidence of passive congestion at the base. The right lung weighed 390 Gm and had some pleural adhesions at the base posteriorly. The liver showed diffuse, yellowish discoloration and marked passive congestion. The spleen weighed 150 Gm and showed passive congestion. The gallbladder contained about fifty small black soft calculi with some stringy mucoid bile. The common bile duct was patent and free from external compression. The pancreas was bile stained but otherwise normal in appearance. The right kidney weighed 120 Gm, the left 100 Gm. The uterus, ovaries and appendix were absent. Permission for examination of the brain was not obtained.

The anatomic diagnoses were parenchymatous degeneration of liver with jaundice (arsenical?), gangrene of lower two thirds of both legs, atherosclerosis of right femoral artery with partial recent thrombosis in its lower third, atherosclerosis and calcification of the abdominal aorta, narrowing of the coronary arteries, general passive congestion, atrophy of thyroid, (cardiac failure, acute ergotism?).

On microscopic examination (S I G) the tongue showed some fatty infiltration of the musculature. The sections of the lungs showed patchy areas of atelectasis and early fibrosis containing many thickened and narrowed arterioles. The myocardium showed slight to moderate myocardial hypertrophy and slight fatty infiltration. There was necrosis of the liver parenchyma which involved principally the central portion of the lobules. The Kupffer cells contained bile pigment deposits. There was marked passive congestion the blood sinuses and

the capillaries being dilated and filled with blood. Lymphocytic infiltration was present in the peribulbar and subcapsular stroma. The pancreas was the seat of marked passive congestion and a moderate degree of fatty infiltration. A lymph node (hepatic) showed lymphoid hyperplasia and dilatation of the blood and lymphatic capillaries. In the kidneys there was some atrophy, a moderate degree of passive congestion, cloudy swelling of the tubular epithelium, bile pigment casts within the tubules, and some glomerular scarring. The blood vessels showed the following changes. The coronary artery and its branches in the epicardium and myocardium showed thickening of the walls with prominence of the fibers of the media. The endothelial cells were conspicuous and the lumens of the vessels were narrowed. The coronary veins were widened and largely empty. In the media of the aorta there was an area of perivascular lymphocytic infiltration. The adventitia showed dilatation and congestion of the capillaries. The endothelium was actively proliferating and there was perivascular lymphocytic infiltration. The arterioles of the lungs were many, their walls were thickened on an average to about twice the diameter of the lumens. In a number of these vessels the lumen was reduced to a slit. The arterioles of the pancreas, kidney, liver and lymph node were definitely thickened, but to a lesser extent, the walls being about half the diameter of the lumens in these locations. The capillaries of the pancreas were greatly dilated and engorged with blood. The veins appeared dilated. There was prominence of the endothelium of all the blood vessels of the pancreas. A section of skin taken from the lower part of the right thigh showed in the corium many dilated capillaries with endothelial proliferation and some perivascular lympho-

Fig 5—Arteriole  $\times 90$ , branch of right femoral artery

cytic infiltration. The walls of the femoral artery were thickened. The adventitia contained numerous dilated capillaries with proliferating endothelium and some perivascular lymphocytic infiltration. There was moderate calcification of the media and a large fragmented subintimal atheroma undergoing hyalinization. An area of lymphocytic infiltration was present between the media and the atheroma. The lumen was narrowed. Although the atheroma was fragmented no recent

thrombus was seen. In one section there was adjacent to the femoral artery an arteriole of medium size, which showed marked thickening of its walls to about three times the diameter of the lumen. Its endothelial cells were conspicuous.

#### REVIEW OF LITERATURE

Saenger<sup>1</sup> reviewed the reports by various authors of thirteen cases of gangrene that developed in women with puerperal sepsis following the oral and intramuscular administration of ergotamine tartrate. The total dose in these patients varied from 65 to 117 mg. Saenger did not definitely state whether the gangrene was due to septic vascular disease or whether puerperal sepsis predisposes women to develop gangrene after ergotamine tartrate therapy. In two cases in which the amputated gangrenous extremities were examined, the only pathologic change demonstrable was a contraction of all the arteries. In a third case there was thrombosis of the femoral vein with purulent thrombophlebitis of the dorsal pedis vein of the same side. In two other instances the patients had complained of paresthesias in the extremities before the institution of gynergen therapy.

Labbe, Besançon and Gouyen<sup>2</sup> reported the unfavorable action of gynergen in patients with exophthalmic goiter. One of their patients a woman aged 49 who

anginal pain. Each attack was more severe and of longer duration than the preceding one. Following the third injection she developed a paralysis of the left arm and left side of the face. The authors attributed the anginal attack to coronary artery spasm and the paralysis to cerebral artery spasm. A second patient, a woman, aged 60, with exophthalmic goiter of moderate severity, was given one injection of 0.5 mg. of

Fig. 6—Coronary arteriole in myocardium  $\times 135$

Fig. 7—Coronary arteriole epicardium  $\times 575$

ergotamine tartrate, which was followed by vomiting. A few hours later she died in syncope. They concluded that patients with exophthalmic goiter are particularly susceptible to the action of ergotamine and that in this disease the drug should be used with extreme caution.

Zimmermann's<sup>3</sup> patient, a woman, aged 43, complained of anginal symptoms and a severe anemia due to uterine bleeding. After one day's complete freedom from the vagina following bed rest she was given an injection of one ampule of gynergen. A few minutes thereafter a prolonged anginal attack occurred, and on the following morning the patient died. On the day prior to the administration of gynergen the electrocardiogram showed some depression of the ST interval in leads 2 and 3. Following the injection, the ST interval showed more marked depression in all leads, being particularly pronounced in lead 2. At autopsy there was found extreme narrowing of the mouths of both coronary arteries due to syphilitic aortitis. The author attributed the fatal status anginosus of this patient to a vasoconstrictor action of the gynergen on the coronary system.

had a severe hyperthyroidism with a basal metabolic rate of plus 108 was given three injections of 0.5 mg. each of ergotamine tartrate. Several hours after each injection she was seized with an attack of severe

1 Saenger H. Leber puerperal Gangran bei septischen Zuständen und Gynergenmedikation. *Zentralbl. f. Gynäk.* 53: 386 (March 9) 1929.  
2 Labbe M., Justin Besançon L. and Gouyen J. Accidents consécutifs au traitement de la maladie de Basedow par le tartrate d'ergotamine. *Bull. et mem. Soc. med. d'hop. de Paris* 53: 429 (April 1) 1929.

3 Zimmermann O. Störung der Coronardurchblutung durch Ergotamin. *Klin. Wchnschr.* 14: 500 (April 6) 1935.

Roch's<sup>4</sup> patient had a fracture of two years' standing of the navicular and calcaneus bones of the left foot, with some residual infection. Following a cesarean operation she developed a septic infection and was given injections of slightly less than 3 mg of gynergen daily for four days. On the third and fourth days she developed pain and pallor in all the extremities. On the fifth day lividity developed in the left foot with an associated coldness and cyanosis. Amputation of the foot was necessary. This author believed that gangrene following ergotamine tartrate therapy may be favored by the presence of infection and possibly "by an alteration of the circulatory parts or a derangement of the vegetative nervous system."

McGrath<sup>5</sup> was able to produce gangrene of the tail in white rats by the injection of ergotamine tartrate, the dosage varying from 25 to 100 mg per kilogram of body weight. Pallor and sensitiveness of the part occurred after three to five days, cyanosis and exquisite pain in from six to nine days, blackening in from ten to sixteen days and demarcation in from seventeen to twenty days. This was followed by sloughing of the gangrenous portion. The injection of theelin following the administration of gynergen was able to prevent the development of gangrene in female rats but not in male rats. Pathologically there was marked cellular proliferation and swelling of the intima which was most evident in the small arteries and arterioles. In some sections the lumens were almost completely occluded. The veins were involved to a lesser extent. The large central artery of the tail, as well as the superficial veins, showed a tendency to thrombosis. McGrath<sup>6</sup> was unable to state the effect of ergotamine on the coronary vessels.

Herrick<sup>7</sup> by the injection of from 0.5 to 1 mg of gynergen intravenously in four dogs found that, on the average, the blood flow in the femoral artery was diminished to 25 per cent of normal. In two other dogs the blood flow was diminished to 57 and 35 per cent respectively.

Pool and Nason<sup>8</sup> by injections of ergotamine in cats were able to demonstrate a constriction of the arteries of the dura and the skin. In the former the average decrease in diameter was 25 per cent, in the latter 39 per cent.

#### SUMMARY

The case herein reported is that of a middle-aged woman who developed gangrene of both lower extremities immediately after the institution of ergotamine tartrate (gynergen) therapy. On postmortem examination all the arterioles examined were found to be contracted. The experimental work of McGrath on rats demonstrating the production of gangrene following the injection of gynergen, suggests the possibility of a similar effect in our patient. The vascular disease present in our case would seem to have predisposed to the development of the gangrene. On the basis of the evidence at hand it is suggested that the use of drugs of this type be avoided in cases of vascular disease such as atherosclerosis, Buerger's disease, coronary sclerosis and atherosclerotic narrowing of the mouths of the coronary arteries.

## THE PROBLEM OF THE SPASTIC CHILD

WITH CLINICAL SUMMARY OF ONE  
THOUSAND CASES

ALVIA BROCKWAY, MD  
Surgical Director Orthopaedic Hospital  
LOS ANGELES

This paper is the outgrowth of more than a year's study of 1000 cases of cerebral birth hemorrhage treated at the Orthopaedic Hospital during the past twelve years. It represents a statistical summary of the cases seen and is a crystallization of certain ideas regarding the care and treatment of the spastic patient.

The subject of cerebral birth hemorrhage and its sequelae calls for a comprehensive knowledge in such varied fields of medicine and surgery that no one person can be intimately versed in all its ramifications. I think that this is one of the main reasons why the spastic child has been so shunted about and ignored by the medical profession.

Probably the chief pathologic condition found in the first month of life is injury to the brain from hemorrhage. Various reports indicate that one third of the deaths occurring during labor are due to cerebral hemorrhage. In fact, some believe that brain hemorrhage is almost a physiologic condition attending childbirth. In one series of 500 new-born babies, 9 per cent showed bloody spinal fluid, and in a series of Negro babies the percentage was 14. The incidence of retinal hemorrhage runs as high as 20 per cent.

When one considers the factors at work that make possible rupture of the delicate vessels of the brain, it seems likely that the obstetrician has been too severely maligned. Factors over which he has little or no control must be of greater importance than the isolated cases due to unskilled obstetric care. The suction due to negative pressure after rupture of the bag of waters, strangulation due to the cord wrapped around the neck, the overlarge head subjected to prolonged trauma, the small head which does not allow time for sufficient molding are all factors that are largely beyond the control of the medical attendant.

Probably in less than 50 per cent is there a history of long hard labor or the use of forceps and brain hemorrhage has occurred with cesarean section. In the diplegic cases the history of difficult labor is probably less than 30 per cent. In this series there was a history of prolonged labor in 39 per cent, with 32 per cent for the diplegic cases.

It is believed by some, in the case of diplegic paralysis, that hemorrhage may not be the cause of the spasticity and mental deficiency. Since the legs are involved so much more frequently than the arms, they believe that something must have happened to check the completion of the motor pattern in these children. They believe that definite nerve fiber groups receive their myelin according to a definite chronological schedule and that the myelin is laid down through the agency of the blood. A possible theory for this failure of development of the motor pattern is an interference with myelination in the fetus through changes in the blood of the mother from either some toxic or some endocrine disturbance. In support of this view attention is called to the spasticity and alteration of muscle

A symposium on the care of the spastic patient was prepared by various departments of the Orthopaedic Hospital. Lack of space prevents the presentation of all this material but the author wishes especially to mention Dr. George H. Patten on the neurologic, Mrs. Evelyn Tippet on the psychologic and Miss Ruth Ann on the physical therapy department and to acknowledge free use of the material presented in their papers.

tone that develops in multiple sclerosis when there is loss of myelin sheath that leaves the axis cylinders bare. In support of this view also is the observation in the study here presented that 43 per cent of the patients showed definite endocrine disturbance.

In the accompanying table are given data gathered from this study of 1,000 cases. Because of the size of the series it should be of interest and value to those who are interested in the problems of cerebral birth hemorrhage.

#### EARLY TREATMENT

The early treatment after birth comes largely within the scope of the neurosurgeon. Early surgery to relieve the hemorrhage has not been very successful. The reason for this, of course, is that too often the hemorrhage is so located that it is inaccessible to surgical approach or the hemorrhage is diffuse and widely separated, and the mortality rate is high. However, many men with experience are reporting worthwhile results from frequently repeated spinal punctures until the fluid is free from blood. In case of dry puncture some men have claimed good results with cisternal puncture.

#### LATER TREATMENT

Usually the patient does not come to the attention of the orthopedist until the mother notices that the child is not developing as it should. It has been our experience that very little is done for these children during the first few years of life. Even if the mother consults a physician, seldom is an adequate regimen outlined for the parents. Too often they are dismissed with some brief, perfunctory advice, with the result that the parents consult the irregular practitioners of medicine.

Even before the child is old enough to sit or stand there are definite things to be outlined for the parents until it is old enough to benefit from more formal training under direct supervision. But first the physician must have a clear conception in his own mind of what he is trying to accomplish. He must realize that the spastic child lives largely through his senses of sight and hearing, his muscular or motor expression being considerably limited. Yet it is a biologic law down through the ages that man has grown mentally in direct ratio to the skill he has developed in the performance of constructive motor activities. The spastic child is incapable of expressing in a motor way the ideas of his sensory world. His poor coordination is thus made worse, owing to the accumulation of energy, which is spilled over into vicarious channels. No wonder, then, that these children are usually underrated mentally and that so much pessimism prevails. It explains also why so many of these patients improve mentally as their physical handicap improves through training and surgery.

One of the reasons why treatment of these patients has not been more successful is that those in charge of these patients have approached their problem from too narrow a point of view. As mentioned earlier, adequate coping with this problem can be met only by the combined resources of knowledge from several special fields of medicine. We long ago recognized that a team of workers was necessary, a skilled team that was sympathetic with the special needs and requirements of the spastic child, if he was to receive the maximum that medical science has to offer.

It is true that some orthopedic institutions and orthopedic specialists are interested mainly in the surgical aspect of the problem and pay too little attention to the

#### Statistical Summary of One Thousand Cases of Cerebral Birth Hemorrhage

Age (entered clinic)	69 yrs
Males	57%

mental, recreational, speech and physical therapy training. On the other hand there are no end of schools for spastic patients that center all their effort in physical therapy training. Many of these schools are manned by competent individuals, at least competent

in their special field, but they largely or entirely overlook the surgical and bracing opportunities that may be staring them in the face

These schools will diligently and often expertly train their patients toward better balance and coordination, entirely ignoring contractures that are defeating their efforts. These patients already have difficulty in balance, and unless the flexion deformities of the hips and knees and the equinus deformities of the feet are first corrected by surgery and adequate bracing, they are fighting an uphill battle all the way

In an attempt to open up and develop every possible avenue of approach, the Orthopaedic Hospital has developed a team which we believe indispensable if the maximum end results are to be obtained

#### ROLE OF THE TEAM MEMBERS

*The Orthopedic Surgeon*—In this team the orthopedic surgeon is in charge. He makes the initial examination. He evaluates the surgical and bracing possibilities and sees that the patient reaches the various consultants who may be of help

*The Medical Consultant*—On this team is a medical consultant with an interest and training in endocrinology, since a great number of these patients have an accompanying glandular disturbance. Many also have disorders of digestion and elimination and faulty diet habits. Those having foci of infection are referred to the proper department for correction, as an attempt must be made to relieve these patients of every extraneous physical load

*The Dentist*—Because of their poor mastication, many have dental caries and poor occlusion requiring dental care

*The Psychologist*—A very important member is the psychologist, who has had special training with spastic children. He or she can give valuable information on the intellectual level of the patient, his psychomotor skill, his personality deviations and the training possibilities and he has charge of the mental training. The psychologist is in a position to study personal preferences, desires and ambitions. Thus this department has helped to put the physical therapy training on a sounder psychologic basis. While the exercises attempt to follow definite laws, yet if the desired activity is coordinated with an already discovered ambition—with play, rhythm, music or a definite comprehensible goal in the mind of the child—we have found an unexpected interest that indicates the point of departure toward the next stage of mental training. Many cases could be cited in which there has been a marked improvement in the intelligence quotient rating, accelerated and improved motor function and awakening of the child's interest through the training received in this department. The spastic child is apt to meet frustrations with tantrums. This display of temper and ineffectual response can be altered and improved by the alert psychologist

*The Neurosurgeon*—The neurosurgeon has a definite and useful place on this team. All cases are referred to him for routine examination and to clear up doubtful diagnoses. From this group there will be a small number which will require special neurologic study, consisting of spinal punctures, encephalographies, crural exploration, section of the skull for hydrocephalus, and spinal and ventricular studies for hydrocephalus. The neurosurgeon is in a position to estimate the amount of brain damage and its localization more accurately than others who are not particularly inter-

ested in the structure and pathology of the nervous system. In a few cases in which there were localized adhesions and cysts associated with epilepsy, brain surgery has given definite and worthwhile improvement. Cases of hydrocephalus that show x-ray evidence of increased intracranial pressure are recommended for section of the skull to provide for expansion

#### PHYSICAL THERAPY AND OCCUPATIONAL THERAPY DEPARTMENTS

The physical therapist carries on the work of teaching relaxation, rhythm of motion and gait training. Practically all patients pass through this department, since training of the extremities toward better functional use constitutes a large part of the patient's regimen. The results obtained will depend to a great degree on the skill, resourcefulness, personality and enthusiasm of the technician. Our experience has demonstrated that intensive training is justly rewarded, provided we have a child of from fair to normal intelligence

The primary aim is to teach relaxation, to teach the patient to do simple things without becoming tense and excited. With the young we start first with the grosser motions of the larger joints, having the mother, in a spirit of play, repeat the motions over and over until the motor pattern becomes fixed

With the spastic child, even a simple motor act such as reaching for a toy may be a major undertaking. Unlike the normal child, who automatically and without effort uses only the muscles necessary for the act, the spastic child may put all four extremities into play. The object is to teach him to inhibit those muscles not necessary and use smoothly only those necessary for that particular act

Since we know in advance that certain contractures are apt to occur, we can design exercises that will tend to overcome these overactive muscles. This will mean motions of abduction and external rotation of the shoulder, extension of the elbow, extension of the wrist and fingers, abduction of the thighs, extension of the knees and dorsiflexion of the feet. These simple exercises can be carried out by the mother until the child has advanced sufficiently mentally and physically, to benefit by more formal exercises of coordination and gait training in the gymnasium and the warm pool

The work in the occupational therapy department is of similar character but it has certain advantages in that this type of training seems more like play; it is possible to give greater latitude to the child's preferences and it carries with it the appeal of achievement, an urge to create and the praise that goes with a piece of work well done

#### SPEECH TRAINING

In this study about 15 per cent showed speech defects after the sixth year. We have usually begun the speech training with the psychologist along with the mental training. The desire to talk is inherently strong within every one having any degree of intelligence and we have only to search for a sufficiently powerful motive to effect our purpose. Later when the child has improved through surgery and training, he may be given formal speech training, because now the energy formerly expended in uncontrollable physical motion is available for articulation

That speech training must be a very necessary part of the training is indicated by the fact that even normal children with speech defects are apt to develop peculiarities of personality and unsocial tendencies. Those

trained in speech work can cite many cases of marked improvement in school work and increase in the intelligence quotient from 10 up to as high as 30 per cent after the speech defect has been overcome. Dull normal children have become normal and suspected high grade morons have become dull normal persons.

#### THE SURGICAL AND BRACING ASPECT OF THE PROBLEM

It is unfortunate that so many men feel that surgery and bracing play such a small part in the rehabilitation of the spastic child. That it must be a very important part of the problem is indicated by the fact that, in this series of 1,000 cases, 542 surgical operations were performed, in 38 per cent braces of some sort were worn during part of the treatment, and shoe corrections without braces were worn in 28 per cent of the cases. It must be borne in mind that these figures are from an institution which believes and practices that all available avenues of approach must be made use of if the spastic child is to receive the best there is to offer.

It is a common experience in this institution for the physical therapy department to comment on the better results that exist after contractures and overactive muscles are improved through surgery and bracing. The uphill battle has been made lighter and the patient makes faster progress in balance and walking.

I feel that bracing has a very definite place in the treatment of these cases and believe that the use of braces is founded on sound physiologic principles. In the first place they help to stretch the overactive muscles continuously. Secondly, they minimize the number of joints that are brought into play when walking, so that the child just beginning to take steps can focus his attention on fewer moving parts. At the same time they cut down on the number and degree of excursion of vicarious, incoordinated motions when a voluntary act is attempted. Even after surgical procedures such as neurectomies and operations to lengthen short tendons, the overactive muscles will again bring about the original contracture if they are not kept stretched for a long period in braces.

In this series it will be noticed that 457 of the total of 542 operations were performed on the lower extremities. This preponderance of surgery on the legs and feet is accounted for in part by the fact that the lower extremities are more frequently involved, but chiefly it is due to the fact that the surgeon is more concerned, and rightly so, with making a bedridden or wheel-chair patient walk than he is with increasing function of the arms and hands. Not only does this make a lighter burden for the parents but it changes the whole life of the individual and adds a tremendous impetus in the desire to make further improvement.

Experience has shown that some of the operative procedures have not stood the test of time. In the first place it may be mentioned that transplants of spastic muscles are in general disappointing. Tenotomies and plastic lengthening of tendons are usually more satisfactory than neurectomies. Time has shown that little or nothing was accomplished by ramisection, which were so in vogue a few years ago.

An examination of these patients made it apparent that the possibilities for improvement in the upper extremity were being somewhat neglected, and examination of patients from other clinics indicates that this is a common tendency. The flexion contracture of the hand and fingers yields to continuous stretching in plaster splints, and if accompanied and followed by training the function of the hand can be greatly

improved. The milder pronation contractures of the forearm likewise yield and improve with stretching in plaster, and the severer ones are greatly benefited by transplant of the pronator teres muscle so that contraction of this muscle effects a supination action. Fusion of the wrist is often a very useful measure, provided the fingers have sufficient grasping function. The underslung thumb deformity in which the thumb opposes across the palm in the way of the other fingers when an attempt is made to make a fist is very annoying. I have tried various transplants without marked benefit. Now I do a complete or partial resection of the nerve supply to the opponens or short flexor muscle of the thumb, followed by immobilization in an attitude of abduction, an operation that has given fair success.

Tenotomies of the adductor muscles of the thigh and neurectomy of the obturator nerves for overactive adductors and scissor gait are operations that have stood the test of time. Overcoming the flexion contracture of the knees, in the milder cases by wedging casts and in the severer cases by capsulotomies, will always be a valuable measure, and it enhances the training possibilities. To improve balance, lengthening of short heel cords followed by bracing is always good surgery.

In my hands, partial or complete resection of the nerve supply to the gastrocnemius muscles for overactive calf muscles without actual shortening has not given as good results as stretching and bracing. Stabilization operations for deformed feet and feet exhibiting uncontrolled, purposeless motions are of definite value. The patient is given a more secure foundation and the thrust of the foot against the ground in walking becomes greater and the force is better controlled after such an operation. Certainly surgery has a prominent place in the rehabilitation of these patients.

#### COMMENT

Given a child of fair mentality, an intelligence rating of 80 or above, a great deal can be done for these spastic patients under the regimen outlined. In addition to the surgical and training aspect of the problem, one must be alert to the social and economic problems of patients. Because of their limited means of self-expression, reticence and inferiority complexes, opportunity should be provided for supervised play and recreation. Formation of self-governing social clubs offer an opportunity for leadership. Drama, music, dancing, art and study clubs are all a vital part of the regimen to round out properly the whole life of the individual. Vocational and scholastic training to prepare the patient for a life's job, within the mental and physical limits of the individual, must be provided. After all, the ultimate objective is not merely to correct and improve deformed bodies but to give to society, as far as possible, a reliant, useful and self-supporting citizen.

2400 South Flower Street

**Muscular Tension When at Rest**—When a person loses weight because of worry or of mentally or nervously hard work, it may be largely because of increased muscular tension, not only during the day but also during the night when there is less sound sleep and often also because under nervous tension the appetite may be diminished or the digestion disturbed. Even when we are, as we say, completely at rest there is still tension in all our muscles and a large amount of energy is being spent in maintaining this muscular tension even when it is involuntary and unconscious.—Sherman, H. C. Food and Health New York, Macmillan Company, 1934.

THYROIDECTOMY FOR ANGINA  
PECTORISA CASE OF ANGINA PECTORIS ASSOCIATED WITH  
NONTOKIC GOITER RELIEVED BY TOTAL ABLA-  
TION OF THE LEFT LOBE OF THE  
THYROID GLAND

J DEWEY BISGARD, M.D.

OMAHA

Recently there have been published several reports<sup>1</sup> of observations that extend over a period of one year or more on cases treated by total ablation of the normal thyroid gland for angina pectoris and congestive heart failure, unrelated to thyroid disease. The rationale of the treatment is based principally on the results of an experimental investigation carried out by Blumgart and his associates,<sup>2</sup> by which were confirmed certain impressions that had been deduced by many clinicians from the common clinical observation of the change in circulation and cardiac function brought about in thyrotoxicosis by spontaneous, iodine or surgical remission, and in myxedema by thyroid feeding. They demonstrated that the velocity with which blood circulates varies rather constantly with the metabolic rate

and is therefore dependent on the metabolic demands of the body. Furthermore they observed that blood flows much more slowly than normal in cases of cardiac failure which present normal basal metabolic rates. It was reasoned therefore, that a heart in congestive failure (because it was unable to meet the normal metabolic demands) might establish equilibrium between supply and demand and carry on in compensation at the subnormal metabolic level which results from total thyroidectomy. Furthermore, the same reasoning seemed applicable to cases of angina pectoris as a means to lessen the load on a heart crippled by an impairment of its coronary circulation. This concept had certain clinical precedent. There are on record rare cases in which angina pectoris coexisting with thyrotoxicosis has been relieved by subtotal thyroidectomy. Conversely, patients with myxedema occasionally develop for the first time signs of cardiac failure or of angina pectoris after the administration of thyroid extract and are relieved only after this therapy has been discontinued or quantitatively reduced.

As cases were investigated in which total thyroidectomy had been done, certain interesting facts developed. Among these was the observation that the metabolic rate fell slowly, showing no appreciable reduction for a week or more and that symptoms of myxedema did not appear until from four to eight weeks after operation. And yet the patients with angina pectoris who were benefited experienced relief from anginal attacks immediately after operation, weeks before the metabolic demands on the heart had been lessened significantly.

It is in respect to this problem of the mechanism by which total thyroidectomy relieves angina pectoris that the following case is reported also worthy of record are certain unusual features that the case presents.

**History**—J. W., a farmer, aged 67, who had always lived in a nongouty region stated that until two years before admission he had always had excellent health. For twenty years he had had a goiter but in his history there was no evidence that he had ever had symptoms of hyperthyroidism. The goiter had not changed appreciably in size, but for four years he had noticed pressure symptoms of choking when he turned his head to the right, and particularly so in recumbency.

For two years he had had attacks of sharp precordial pain which radiated into the left side of the neck and to the top of the left shoulder. With the pain there was a sense of compression of the chest inability to breathe and anxiety. The attacks were invariably initiated by exertion and excitement and were particularly prone to occur with exertion immediately following a meal. They had become progressively more frequent and more severe until they completely incapacitated him. For three months he had taken glyceryl trinitrate, which gave him immediate and complete relief.

**Physical Examination**—The patient was well developed and nourished was 6 feet (183 cm.) tall weighed 192 pounds (87 kg.) and appeared younger than the stated age. The exposed skin surfaces were tanned very deeply and the lips were slightly cyanosed. There was some porphyria alveolaris.

Protruding in the neck was an obvious goiter, which to palpation involved both lobes was firm nodular and freely movable and in the aggregate was the size of a large orange. Both lobes appeared to extend subternally.

The chest was barrel shaped, the lungs were emphysematous with a few atelectatic rales at both bases and the heart was normal in size and rhythm with a rate of 60 (resting) and a systolic murmur heard over the entire base. To the left of the sternum and extending from the nipple up over the shoulder and base of the neck was an indefinite band of hyperesthesia and hyperalgnesia. There was moderate arteriosclerosis and the blood pressure was 132 systolic 75 diastolic. The reflexes were normally active and the remainder of the examination was negative.

**Laboratory Examination**—The urine was acid, had a specific gravity of 1.020 and contained no sugar or albumin, the sediment was negative. The blood showed hemoglobin 90 per cent, red blood cells 5,200,000, white blood cells 5,800, and a differential of 64 per cent polymorphonuclear leukocytes and 36 per cent lymphocytes. The basal metabolic rate was minus 32, and because this initial reading was so low as to cause doubt of accuracy the test was repeated with the result of minus 28. The electrocardiogram was normal except for the bradycardia. Fractional gastric analysis gave normal values for both free and total acid. Blood cholesterol was 173 mg per hundred cubic centimeters, blood chlorides 421 mg, and fasting blood sugar 104 mg. Dextrose tolerance was reduced, the readings are given in the accompanying table with those obtained after operation.

**Operation**—Feb 21, 1935, with local infiltration anesthesia, both lobes of the thyroid gland were exposed and found to have large substernal prolongations. Both were made up of adenomatous nodules many of which were cystic, and the left lobe was extensively calcified. The right lobe was removed subtotally, leaving only a small remnant, but the left lobe was totally removed, leaving no thyroid tissue whatever on the left side of the trachea. Microscopic changes in the tissue confirmed those apparent in gross examination.

**Postoperative Course**—The patient had an uneventful convalescence and from the day of operation until the present writing, a period of eleven months, he has had no attacks of

Dextrose Tolerance Curves

	Before Operation, Mg per 100 Cc	After Operation	
		2 Weeks Mg per 100 Cc	6 Months Mg per 100 Cc
Fasting	104		76
1st half hour	213	177	156
2d half hour	292	248	163
2d hour	332	280	199
3d hour	291	160	121
4th hour	193	120	142

angina pectoris such as he had before operation. On rare occasions and then only with excessive exertion, he has experienced some slight substernal discomfort. Whereas he was completely incapacitated before operation, he has engaged daily in light work on the farm during the past nine months. The area of hyperesthesia and hyperalgesia over the precordium and shoulder noted before operation disappeared immediately after operation and to the present has not returned.

Curiously two weeks after operation, the basal metabolic rate was minus 18 and the dextrose tolerance curve was relatively normal. The blood cholesterol was 152 mg per hundred cubic centimeters and the fasting blood sugar 76 mg. The tolerance curve is given in the table. Six months after operation the basal metabolic rate was minus 5 per cent and the dextrose tolerance as given in the table.

## COMMENT

As was stated previously, it has been observed constantly that relief in cases of angina pectoris occurs immediately following total extirpation of the thyroid gland. This occurs as has been shown by Levine and Eppinger<sup>3</sup> and by Blumgart and his associates,<sup>4</sup> several days before there has been an appreciable reduction in the basal metabolic rate, in the velocity of blood flow and presumably in the quantity of circulating secretion of the thyroid gland. This immediate relief is attributed by Weinstein and Berlin and their associates,<sup>5</sup> to inter-

ruption of "cardiac afferent nerve pathways" or "afferent nerve impulses from the heart" at the time of operation. They support this hypothesis by observations in nineteen cases in which they were able to demonstrate partial or complete disappearance immediately after operation of both nonanginal precordial pain and of preoperative areas of skin hyperesthesia and of muscle and periosteal hyperalgesia of the chest wall. After from two to four weeks these signs reappeared with a recurrence of anginal attacks if a sufficient fall in the metabolic rate had not taken place, and they disappeared permanently only with the establishment of an adequate hypothyroid state. Similarly, temporary relief of anginal pain and of hyperesthesia and hyperalgesia occurred in each of three cases in which there had been performed only a total hemithyroidectomy. These changes, however, were limited to the corresponding side of the chest and disappeared permanently only after the other half of the gland had been removed at a second stage. From these observations they were led to believe that the "nerve" relief is only transitory and that permanent relief is brought about by the reduction in cardiac load resulting from lessened metabolic demands.

Levine and Eppinger<sup>3</sup> and Cutler and Schmitker<sup>7</sup> have offered a very different explanation for both the immediate and the permanent relief of attacks of angina pectoris. They believe that total thyroidectomy relieves these attacks by altering the epinephrine effect on the heart. They suggest that the heart is rendered less sensitive to epinephrine for the reason that they found that, whereas the subcutaneous injection of from 0.3 to 1 cc of a 1:1,000 solution of epinephrine produced severe attacks of angina pectoris in their patients before operation, it produced either no pain or greatly modified attacks when administered as early as twenty-four or forty-eight hours after operation. From a similar investigation Riseman, Gilligan and Blumgart<sup>8</sup> found that the clinical improvement after total thyroidectomy was independent of any change of sensitivity to epinephrine and, contrary to the observations of the former investigators, they could demonstrate no change in sensitivity as judged by the heart rate, the blood pressure, the rate and depth of respiration, the consumption of oxygen, and the blood sugar levels in their patients until they had developed definite clinical myxedema. No mention is made regarding alterations in the pain response. Experimentally, however, Sawyer and Brown,<sup>9</sup> have shown that the tachycardia response to epinephrine in the isolated perfused heart is increased by the addition of thyroxine and is less than normal in the hearts of animals that had previously been totally thyroidectomized.

As further evidence that a reduction in the delivery demands on the heart is not solely responsible for relief of angina pectoris as maintained by Blumgart and his associates, it was found by Levine and Eppinger<sup>10</sup> that

in certain of their cases presenting congestive heart failure the rate of blood flow was unaltered by total thyroidectomy despite the development of myxedema and of clinical improvement. To add further confusion to this controversial subject, Lyon and Horgan<sup>11</sup> have reported five cases of angina pectoris unassociated with thyroid disease in which prolonged and, up to the time of their report, permanent relief had resulted merely from ligation of the superior and inferior thyroid arteries on both sides. One patient had had no attacks of angina pectoris for ten months, one for five months, and three for more than three months. In the first case the basal metabolic rate had receded from plus 5 to minus 13. They attribute the relief in their cases to two factors: (1) a lowering of the metabolic rate from diminution in the blood supply of the gland, and (2) interruption of the sympathetic stimuli to the gland and of the intercommunicating nerve pathways between the gland and the heart.

In the light of the foregoing information an attempt will be made to analyze the mechanism of relief in my case. This patient presents an unusual clinical picture of angina pectoris associated with an old substernal degenerated adenomatous goiter and with a hypometabolic state without symptoms of myxedema. Undeniable is the possibility that the very low preoperative metabolic rate of minus 32 was inaccurate. It was measured, however, in an excellent laboratory and repeated with approximately the same result. In consideration of this low rate it seemed unwise to deprive the patient totally of thyroid tissue, and since the pain had always been confined to the left side it seemed probable in the light of the experience of Lyon and Horgan<sup>11</sup> that it might be relieved by subtotal thyroidectomy, the left lobe, however, being removed completely. This procedure gave not only immediate but also prolonged (now eleven months) relief from angina pectoris, and the relief developed not as a result of hypothyroidism but rather in the presence of sufficient thyroid tissue to maintain a normal metabolic rate.

In the discussion that follows, it should be emphasized that there has been no intent to draw conclusions with general implications. Such conclusions cannot be made from a single case, nor can the clinical picture and results in this unorthodox case be compared directly with those investigated by Blumgart, Cutler, Levine and their associates, in which cases the thyroid glands were normal. For instance, it is possible, though I believe unlikely, that the attacks of angina pectoris in this case were caused by pressure from the substernal portion of the goiter on nerves or other structures in the anterior superior mediastinum and that release of this pressure brought about relief. Again, relief may have resulted merely from the removal of the large mass of abnormal thyroid tissue. Coller<sup>12</sup> has observed that certain cardiac irregularities in cases presenting nontoxic goiters disappeared after subtotal thyroidectomy, although the metabolic rates remained normal.

No determinations were made of the rate of blood flow before or after operation but if the metabolic rate is an index to the rate of flow as stated by Blumgart it is reasonable to assume that the velocity was increased rather than decreased. Disregarding this speculation, the fact remains that there has been pro-

longed relief in the presence of a normal metabolic rate and that a reduction in the metabolic demands on the heart has played no part.

Interruption of the sympathetic nervous innervation of the left lobe of the gland obviously was accomplished at operation and if this represents the mechanism of relief in this case it differs from that observed by Weinstein and his associates.<sup>5</sup> As in their cases in which hemithyroidectomies had been done there was an immediate loss of the preoperative hyperesthesia and hyperalgesia of the thoracic wall, but in my case these abnormal sensory manifestations and attacks of angina pectoris did not return in a few weeks and have not recurred to date (eleven months).

It has been suggested that there exists direct nervous communication between the heart and the thyroid gland independent of the sympathetic or other nerve trunks and that these pass from the heart upward in the adventitia of the aorta, innominate carotid and superior and inferior thyroid arteries. Only by virtue of some such mechanism could one rationalize the prolonged relief of angina pectoris in the case here presented and in the cases reported by Lyon and Horgan on a basis of interruption of nervous impulses. In assuming that the operation merely interrupted communications between the gland and the cervical sympathetics, one has difficulty in comparing the results in these cases with those obtained from the extensive operation of cervical sympathectomy as devised by Jonnesco.<sup>13</sup>

No studies of sensitivity to epinephrine were made in this case, and for an obvious reason. However, since there was at all times sufficient circulating thyroid secretion to maintain a normal metabolic rate the theory of relief of angina pectoris from a reduction of sensitivity to epinephrine as advocated by Levine, Cutler and their associates,<sup>14</sup> seems inapplicable. It is probable that some change did occur in the interrelationship of the thyroid and adrenal glands, and equally probable in the interrelationship of all members in the endocrine system. In support of this contention are the changes that occurred after operation in the metabolic rate (an elevation from minus 30 per cent to minus 5 per cent) and in the metabolism of sugar, which shifted from preoperative abnormality to postoperative normality. That the pituitary and adrenal glands are capable either directly or indirectly of exerting a profound influence on both the general metabolic rate and the metabolism of sugar is supported by much clinical and experimental evidence. Also there is increasing evidence that there is a close interrelationship between the functions of the sympathetic nervous system and the endocrines, particularly those glands which have with the sympathetic nervous system a common embryologic origin. Since endocrinology lends itself so readily to romantic fancy it seems not out of place to suggest that a part of the cardiac benefit from total thyroidectomy results from a change in the state of the general vascular bed, the tone of which is controlled by the adrenals and sympathetic nervous system. This is suggested in the words of Levine and Eppinger<sup>10</sup> "the essential change [as the circulation and cardiac function in congestive failure improve] being an improvement in the back pressure factor, i. e., diminution of venous or pulmonary engorgement."

# INFECTIVITY OF THE SPINAL FLUID IN LYMPHOGRANULOMA INGUINALE

EMMERICH VON HAAM, MD  
AND  
RIGNEY DAUNOY, MD  
NEW ORLEANS

Because of the usual location of its primary lesion and its close epidemiologic relation to sexual life, lymphogranuloma inguinale must be grouped with the venereal diseases. Whether the infection in human beings leads to a systemic disease or whether it produces only local lesions is of vital importance to its proper evaluation and the planning of appropriate therapeutic measures.

It has been shown by numerous experiments that inoculation of infectious material into various animals will frequently produce general dissemination of the virus with the appearance of lesions remote from the site of inoculation.<sup>1</sup> While numerous reports maintain the frequency of extragenital lesions—skin, joints, eyes, meninges—during the course of the disease in man, no definite proof exists that such lesions are directly ascribable to the virus. On the other hand the history of the average patient suffering from lymphogranuloma

*Animal Passage of Virus Recovered from Glands and Spinal Fluid*

Pro- total	Character and Duration of Lesions	Diagnosis		Evidence of the Virus in	
		Frei Reaction	Biopsy	Buboes	Spinal fluid
27	Right inguinal bubo nine days	Positive	Positive	Positive 5 passages	Positive 14 passages
36	Bilateral inguinal bubo one month	Positive	Positive	Positive 5 passages	Negative 3 passages
43	Left inguinal bubo eight days	Positive	Positive	Positive 4 passages	Negative 3 passages
42	Left inguinal bubo ten days	Positive	Positive	Positive 13 passages	Positive 3 passages
40	Right inguinal bubo five days	Positive	Positive	Positive 3 passages	Negative 3 passages
41	Right inguinal bubo two weeks	Positive	Positive	Negative 0 passages	Negative 3 passages
45	Left inguinal bubo, four days	Positive	Positive	Positive 8 passages	Negative 3 passages
32	Bilateral inguinal bubo two weeks	Positive	Positive	Positive 5 passages	Negative 2 passages

inguinale suggests in many respects the presence of a generalized infection. During the acute stage of the disease we have encountered quite regularly severe constitutional symptoms, such as fever up to 100 F or higher accompanied by chills, weakness, anorexia, profuse night sweats, and violent headaches. In the literature the importance of the initial rise in temperature has been repeatedly stressed as a valuable aid in distinguishing lymphogranuloma inguinale from other local venereal lesions.<sup>2</sup> Of equal importance, although not sufficiently emphasized is the early occurrence of headaches. The pain is usually described as dull, pressing in character principally in the upper part of the forehead, radiating occasionally into both temples and into the eye sockets. Sometimes it is accompanied by vertigo and nausea, forcing the patient to remain in bed. Sensitivity to light with marked conjunctivitis and occasional stiffness of the neck with pains radiating toward the back of the head in our experience have also been encountered quite frequently.

Aided in part by a grant from Parke Davis & Co.

1931.

The headaches observed with such regularity in the acute stage of the infection suggested to many authors some type of cerebral involvement during the initial phase of the disease. This naturally led to investigation of the spinal fluid. Ravaut and Scheikevitch<sup>3</sup> could not detect any changes in the spinal fluid. Midana and Vercellino<sup>4</sup> found positive Pandy and Nonne reactions, with increased cell counts in two of eleven fluids examined. Kitagawa's<sup>5</sup> interesting finding of marked increase in the intraspinal pressure could not be confirmed by Chaigneau<sup>6</sup> or Espildora and Coutts.<sup>7</sup> Coutts, Landa, Perroni and Martini Herrera<sup>8</sup> report inconclusive results with complement fixation tests on spinal fluids, using an antigen prepared from excised buboes. Because of the apparent conflicting results obtained by various authors, we decided to study the spinal fluid in a series of acute cases of lymphogranuloma inguinale and to attempt by means of animal experimentation to prove or disprove the presence of the virus in the spinal fluid.

For our studies we selected only patients in the acute stage of the disease. They all presented in a greater or less degree the aforementioned characteristic constitutional symptoms of fever and headache and had suffered with painful inguinal buboes for from a few days to two weeks. Each gave a strongly positive Frei reaction and a negative blood Wassermann reaction, and adenectomy was done in each case. Intracerebral inoculation of 10 per cent emulsions of excised buboes into white mice revealed in all cases the presence of the virus, and the histopathologic picture of the excised gland was in all instances typical of the disease. Spinal fluid from these patients was inoculated intracerebrally in 0.01 cc portions into white mice. Some of the animals were killed after two weeks for further animal passage and histologic examination of their brains. Others were kept under observation until the onset of the characteristic symptoms. In all cases inoculation of gland emulsions resulted in the production of typical clinical and histopathologic changes. In two of the cases inoculation of the spinal fluid was followed by similar changes. The viruses recovered from the glands and the spinal fluids were carried through several animal passages as indicated in the accompanying table. The strain recovered from the spinal fluid in case 27 still being carried for further biologic studies. Brain emulsions from the animals successfully inoculated with the spinal fluid from patients 27 and 42 gave strong cutaneous reactions in patients infected with lymphogranuloma inguinale.

## COMMENT

In a previous communication we discussed the possibility of lymphogranuloma inguinale being under certain conditions a systemic infection in man. On the basis of our own clinical and experimental observations and of data available in the steadily mounting literature, we concluded that there is much evidence at least suggestive of frequent generalized dissemination of the virus during the early stages of the disease. In a recent paper Coutts,<sup>9</sup> who is the outstanding investigator of this disease in South America, takes a similar point of view and even goes so far as to divide the disease into

three distinct periods or stages similar to those noted during the evolution of syphilis. According to him, the time elapsing between infection and the appearance of the primary lesion must be regarded as the primary incubation period and may extend up to three weeks. This is followed by a secondary period characterized by the appearance of constitutional symptoms, inguinal buboes and occasionally generalized lymphadenitis, skin lesions, conjunctival lesions and anemia. Lesions of the tertiary period are elephantiasis of the genital organs, ulceration of the vulva (esthiomene) and rectal stricture. Although we are inclined to consider the conclusions of Coult's premature on the basis of the available clinical observations on the various manifestations of the disease, we cannot deny that such a concept may yet prove correct.

Our successful demonstration of the virus in the spinal fluid of infected patients certainly proves that dissemination of the virus in the human body actually occurs. Study of the spinal fluid in a large number of cases alone will prove whether this reported observation must be regarded as the rule or as an exception during the course of the disease. Even should the latter prove true, our observations give a firmer basis to the incrimination of the virus as the causal agent of the cerebral manifestations occurring during the course of lymphogranuloma inguinale, as described in increasing frequency by continental authors.

#### USE OF THE FEMALE BITTERLING AS A TEST FOR MALE HORMONE

ISRAEL S. KLEINER, PH.D.  
ABNER I. WEISMAN, M.D.  
AND  
DANIEL I. MISHKIND, B.S.  
NEW YORK

In 1934 Kanter, Bauer and Klawans<sup>1</sup> reported a new biologic test for hormones in pregnancy urine. The title as well as the text intimated, although it did not positively assert, that the procedure might be useful in diagnosing pregnancy. The technic requires the addition of a small amount of the suspected urine to an aquarium containing a female bitterling. These fish possess an ovipositor which in the quiescent state is from 2 to 5 mm long. A positive reaction is denoted by an elongation of the ovipositor to a length of about 25 mm. The simplicity of this test aroused widespread interest, and many workers desired to use it, believing that it was a test for pregnancy.

However, it was demonstrated<sup>2</sup> that this remarkable phenomenon is not a pregnancy test, since distinctly positive reactions were obtained with some urines from males, nonpregnant females and women in the post-climacteric period. Furthermore, pregnancy urines did not all give positive reactions.

It was thus evident that some factor present in a wide variety of urines not solely related to pregnancy was responsible for the ovipositor test. This conclusion has been corroborated by various workers in other laboratories. We have also found that a larger per-

centage of male urines will react than we had first reported. In fact, every normal male urine recently tested has proved positive if a large enough dose of urine could be used without harming the fish.

In the attempt to determine the cause of this phenomenon we have tested many substances, including crystalline theelin and theelol<sup>3</sup> as well as various proprietary hormone preparations, including a number estrogenic in nature. As a result of these tests we arrived at the hypothesis that the responsible factor was not one of the female sex hormones but one of the so-called male hormones.

This is a more logical hypothesis than would at first thought seem to be the case. Since the ovipositor stimulating substance or substances are added to the water in which the female fish swims, it would appear that she reacts to a hormone contributed from a source outside her own organism. That this source might be a male bitterling would seem likely, since the lengthening of the ovipositor occurs normally as a part of the reproductive cycle in the spawning season and when the female is in close association with the male. We have never noticed spontaneous ovipositor lengthening during the breeding season when the females were kept segregated from the males. When the breeding season occurs, it is probable that the male secretes his hormone and excretes it into the water near the female. She is thereby stimulated to react by a lengthening of the ovipositor, through which the ova pass when being deposited at their natural site. This hormone mechanism would insure the presence of a male in the neighborhood of the female at spawning time. Naturally this hypothesis presupposes that the male hormone of the fish and that of man have similar activity. In brief the male hormone furnishes the necessary stimulation to induce ovipositor elongation in the female.

The following is an outline of a typical experiment which indicates that the idea is correct. Eighteen liters of mixed male urine was treated according to the methods of Funk, Harrow and Lejwa<sup>4</sup>; Butenandt and Tscherning,<sup>5</sup> and Kochakian and Murlin,<sup>6</sup> yielding two fractions (a) containing male hormone and (b) containing female hormone. Portions of a and b were emulsified and added in varying doses to aquariums containing female bitterlings in the quiescent stage. Positive reactions with the fish were obtained only with the male fraction (a). As confirmatory evidence that a contained the male hormone, it was injected in oil solution into a capon. It produced the well known comb and wattle growth. The other fraction (b) did not have this effect on the capon. Oil solutions of a and b were also injected into immature mice. Both fractions caused estrus. However, it has been shown by several investigators<sup>7</sup> that the male hormone has estrus-producing properties when concentrated.

It is thus evident that the male hormone present in male urine, presumably androsterone, produces the ovipositor lengthening reaction in the female bitterling.

3 We are indebted to Prof. Edward A. Doisy for samples of crystal theelin and theelol.

The anterior pituitary-like hormone does not give this test. Fractions containing theelin and theelol, and these crystalline hormones themselves, do not give this reaction or do so in a very slight degree.

We suggest the use of this reaction as a new test for male hormone. It is extremely simple, inexpensive and time saving. A positive reaction is usually seen at the end of from eighteen to twenty-four hours. Sometimes the ovipositor continues to grow during the second twenty-four hours.

In order that the test may be used in a uniform manner by all, we suggest a procedure and at the same time define a unit as follows. One bitterling unit is the smallest amount of material which, when added to an aquarium containing two female bitterlings in 4 liters of water, will cause marked lengthening of the ovipositor (to the end of the anal fin or beyond) in at least one of the two within forty-eight hours. Other necessary conditions are (1) the fish must have been in the test aquarium for from eighteen to twenty-four hours before the suspected material was added, and (2) at least half of the water used should be taken from the stock tank.

#### COMMENT

The simplicity of the bitterling test should make it of great value in the isolation and purification of male hormone. It should also aid in the establishment of a definite clinical diagnosis of many endocrine disorders.

The details of this work will be published in another journal in the near future.

### AN INSTITUTIONAL OUTBREAK OF EPIDEMIC JAUNDICE

JOSEPH C WILLETT, DVM

EMANUEL SIGOLOFF, MD

AND

CLIFFORD L PFAU, AB

ST LOUIS

In October 1934 an outbreak of jaundice occurred among the students attending a religious novitiate in St. Louis County. Permission to investigate this outbreak was granted by the state health officers when two cases were hospitalized in a St. Louis Hospital. Since epidemic jaundice is not reportable, we have no authentic information regarding the occurrence of similar outbreaks.

The school consists of 132 male students divided into three groups: sixty-two juniors, aged between 16 and 17 years, thirty-six seniors, aged between 19 and 20 years, and thirty-four scholastics, aged between 21 and 22 years. The groups are separated in that they have different dormitories, refectories and class rooms. Contact between them is nil except on Sunday, when members of the same family alone may meet. All groups attend chapel daily but each group is kept separate. The routine housework is done by the students themselves.

The outside help consists of those employed in the kitchen, a carpenter, an engineer, a chauffeur, two tailors, and a bookkeeper. The chapel is open to the public, but services are not attended jointly by the outsiders and the students. There is a separate entrance for the outsiders.

From the Laboratory Section of the St. Louis Health Division. The authors were assisted by Dr. Joseph Grindon in the collection of clinical data.

#### EPIDEMIOLOGY

There are four sources of water supply available to the institution, two springs in shallow limestone and two deep drilled wells. The spring water is used only to fill the swimming pool and cannot be pumped through the distribution system. The two deep wells are so located and installed that apparently there is no opportunity for contamination entering the top of the casing. From the wells the water is pumped to an elevated storage tank located on a hill above the institution. The storage tank is constructed of masonry walls extending above and below the ground. The cover of the tank is constructed of wood and provided with a screened ventilator, the top is not tight enough to prevent aerial pollution, and there are openings between the roof and the masonry walls large enough to admit small animals.

The grounds of the institution were well kept, all the buildings were in a good state of repair, and sewage was disposed of through a water carrying system. There were a few rats on the premises but there was no unusual increase in the rat population noticed at the time of the epidemic. The institution was free of blood sucking insects, and there had been no complaint on the part of the students during this time of having suffered insect bites.

During the month of August 1934 the junior students were away on their vacation and the senior students had just completed an eight-day retreat during the latter part of this month. September 1 the first case of jaundice appeared in a senior student. Inspection of table 1 reveals the occurrence of another case on September 2, two on the 4th, and one each on the 10th and 29th. One case occurred on October 10, 17 and 25, and the last on November 7, making a total of ten cases.

It was not until September 23 that the first case occurred among the scholastics. Additional cases occurred September 24 and 28, October 1 and 4, and November 6. Sixteen cases of jaundice occurred among the junior students. These cases occurred between October 7 and December 9.

In all, thirty-two students, or about 25 per cent of the entire student body, became jaundiced. In addition to these cases, six junior students presented similar symptoms except for the absence of jaundice. Only one older adult, an instructor, out of a total of sixty-eight, became jaundiced, but unfortunately he was absent during the course of the investigation. Table 2 gives the case rate of epidemic jaundice according to the groups.

A child of one of the help residing near the institution who attended services at the chapel likewise developed jaundice. A detailed report of this case was never obtained. This is the only authentic instance of jaundice appearing in an outsider.

#### SYMPTOMATOLOGY

The disease was relatively mild in the majority of cases. In typical cases there was a slight initial elevation of temperature with several days of nausea, vomiting, anorexia, abdominal pain, constipation, clay colored stools, and bile stained urine. In some cases a hard chill initiated the illness. Jaundice was universally present in the cases analyzed and usually appeared between the first and the fourth day, in four instances it occurred on the seventh and eighth day and in one on the twelfth day. Icterus of the sclera alone was noted in a few cases. As a rule, however, the jaundice

was widespread and varied from a light yellowish brown to a deep brown tint. The duration of the jaundice extended from three days to twenty-two days, disappearing most commonly between the seventh and tenth days.

Abdominal pain localized to the right upper quadrant was a common complaint. The spleen was palpable in only three out of seven cases that we examined. The fever ranged from 99 to 104 F. Weakness and prostration were common complaints and often continued through convalescence. Loss of weight in a few students was quite striking. The illness lasted from a few days to four weeks. No deaths occurred during the outbreak. The blood picture showed a mildly infectious condition.

Only two patients were hospitalized, the remainder being treated at the school by school physicians. Detailed routine clinical laboratory examinations could not be made because of the lack of proper facilities. Table 3 gives a list of the symptoms noticed and the number of cases exhibiting them.

TABLE 1—*Date of Onset of Epidemic Jaundice and Weekly Distribution of Cases According to Groups*

	Group (Week That Ended)															
	September				October				November				December			
	7	14	21	28	30	7	14	21	28	31	7	14	21	28	30	31
Juniors	0	0	0	0	0	1	4	4	3	1	1	1	0	0	0	0
Seniors	4	1	0	0	1	0	1	1	0	1	0	0	0	0	0	0
Scholastic	0	0	0	2	1	2	0	0	0	0	1	0	0	0	0	0
Total	4	1	0	2	2	3	5	5	4	1	3	1	0	0	0	0

The clinical picture, we felt, suggested the possibility of Weil's disease. In order to establish this diagnosis it was necessary to demonstrate *Leptospira icterohaemorrhagiae*.

#### LABORATORY INVESTIGATION

Guinea-pigs were chosen as the experimental animal. In this connection Topley and Wilson<sup>1</sup> state: "*Leptospira icterohaemorrhagiae* is highly pathogenic for guinea-pigs whether administered intraperitoneally, subcutaneously, cutaneously or by mouth, resulting in an illness lasting five to twelve days and terminating in death."

In only four cases were we able to obtain blood specimens in the first seven days of the disease. It was not considered worth while to make animal inoculations with blood specimens after the tenth day. Forty-eight specimens of urine and eight specimens of saliva

TABLE 2—*Case Rate of Epidemic Jaundice According to Groups*

	Juniors	Seniors	Scholastics	Total or Average
Ages year	16-17	19-20	21-22	
Number of students	62	36	34	132
Cases	16	10	6	32
Rate	25.8	27.7	17.6	24.2

were studied by darkfield examination and by guinea-pig inoculations. All darkfield examinations were negative for organisms of the *Leptospira* group and none of the guinea-pigs developed any symptoms of jaundice. Postmortem examinations of animals dying and those killed failed to show pathologic changes indicative of infection with *Leptospira icterohaemorrhagiae*.

<sup>1</sup> Topley, W. W. C. and Wilson, G. S. *The Principles of Bacteriology and Immunity*. New York: William Wood & Co. 2: 1200. 1939.

rhagiae. Repeated examinations of urine specimens of inoculated guinea-pigs failed to show *Leptospira*. Guinea-pigs inoculated were killed at intervals of from eight to ten days, and various organs were macerated and reinoculated into other pigs. Negative results were obtained in all cases. Centrifuged specimens

TABLE 3—*Frequency of Symptoms in Thirty-Two Cases of Epidemic Jaundice*

of the institution's water supply were studied by darkfield examination and by guinea-pig inoculation with negative results.

#### WATER FROM HOLY WATER FONTS

A total of nine specimens were collected from fountains serving both students and transients, located in five different places in the institution. All these samples showed organisms in great numbers, identical in morphology and motility with *Leptospira icterohaemorrhagiae*. In this regard Buchanan<sup>2</sup> reports having produced fatal jaundice in guinea-pigs with *Leptospira* isolated from roof slime of a coal mine. Hindle<sup>3</sup> isolated spirochete-like organisms from London drinking water thought to be mildly pathogenic for guinea-pigs.

Efforts were made to infect guinea-pigs with the organisms we isolated. Guinea-pigs were inoculated

TABLE 4—*Number of Guinea Pig Inoculations Made with Specimens from Cases of Infectious Jaundice and from Water Supply*

Material	Number of Inoculations
Human urine	56
Human blood	12
Human saliva	6
Water and water culture material	60
Guinea pig urine	18

Total	146

with these organisms intraperitoneally, intracardially, intracutaneously, intranasally, by ingestion and by ocular instillation. Scorbatic pigs were inoculated, also pigs that had received intramuscular inoculation with irritants. In no instance were we able to establish infection. Efforts were made to enhance the virulence by cultural methods in rabbit's serum and by serial transfers from animal to animal. These tests were negative. No serologic studies were made in connection with this investigation and no rats from the affected area were submitted for examination. A summary of the extent of the laboratory work in connection with this outbreak is given in table 4. This table does not include oral, nasal and conjunctival inoculations. Darkfield examination of the water from

<sup>2</sup> Cup containing a sponge saturated with holy water.

<sup>4</sup> Hindle, Edward. *Leptospira* in London Water. Brit. M. J. 2: 57 (July 11) 1925.

fonts after the epidemic had subsided continued to show *Leptospira*, although the organisms were decidedly fewer in number

#### COMMENTS

Outbreaks of epidemic jaundice have been reported in practically all states in the union. In many instances they were described as outbreaks of Weil's disease without complete laboratory proof being established. That certain forms of *Leptospira* found in stagnant water may produce a mild infection in epidemic form was postulated by Noguchi. Towler and Walker<sup>5</sup> found only six cases of infectious jaundice in the United States between 1922 and 1926 in which *Leptospira icterohaemorrhagiae* was demonstrated.

Many authors agree that epidemic jaundice is due to some factor not recognized at the present time. Hiscock<sup>6</sup> described an outbreak similar in many details to ours, occurring in sixty-nine Yale students. He was unable to demonstrate the etiologic agent. He concluded that these cases originated in contact infection either by direct transfer from person to person or in some instances by infection of eating utensils. Wadsworth,<sup>7</sup> reporting the occurrence of infectious jaundice in New York State, did not find *Leptospira icterohaemorrhagiae* in eighty-seven specimens of urine and thirty-six specimens of blood by guinea-pig inoculations. Waters<sup>8</sup> reported a series of 150 cases of jaundice in which the laboratory studies were negative.

Blumer<sup>9</sup> reviewed the status of infectious jaundice in the United States and noted that

1 Seventy two per cent of the epidemics occurred during the fall and winter months and only 10 per cent appeared in summer

2 The disease primarily involves the childhood and young adult population. In 70 per cent of the epidemics, children and young adults alone were affected

3 The spread of the disease occurs by direct contact. Rats were implicated but in some epidemics rodents were not found

The chief interest in the outbreak being reported centered on the finding of *Leptospira* in the holy water fonts. The sanitary condition of the fonts was promptly improved, with the resultant sudden cessation of cases. One month later, however, one more case developed in a boy whose duty consisted of replenishing the holy water in the fonts. There were no additional cases.

*Leptospira* was found in large numbers in the fonts located at both the transient and the student entrance to the chapel. Since the chapel was used by all members of the institution in common, it is difficult to minimize the importance of this observation. It is entirely possible that the epidemic was subsiding at the time the fonts were disinfected and that the finding of *Leptospira* was of no significance. Direct contact undoubtedly played a role, but to what extent is open to conjecture. A fact which cannot be overlooked is our failure to reproduce the disease in guinea-pigs. What role *Leptospira* played in the dissemination of the disease is difficult to ascertain.

#### CONCLUSIONS

In an outbreak of jaundice involving thirty-two students out of a total of 132, *Leptospira* morphologically identical to *Leptospira icterohaemorrhagiae*

was readily demonstrated in samples of water removed from holy water fonts. Attempts to reproduce the disease in guinea-pigs in which water from the fonts, blood, urine and saliva from patients were used were unsuccessful.

When the sanitary condition of the fonts was improved, the epidemic subsided. The relationship of *Leptospira* to the dissemination of the outbreak cannot be ascertained. It would seem that this epidemic was of nonleptospiral origin.

## INVOLVEMENT OF THE NERVOUS SYSTEM IN TRICHINIASIS

H. HOUSTON MERRITT, M.D.

AND

MILTON ROSENBAUM, M.D.

BOSTON

It has been known for some years that the nervous system may be involved in cases of trichiniasis, but to date there have been few reports in the literature. Recently two patients with neurologic complications of trichiniasis were seen in the neurologic unit of the Boston City Hospital. The diagnosis in these cases was made with great difficulty. We thought it would be advisable, therefore, to report these cases and give a brief review of the literature.

#### REPORT OF CASES

**CASE 1—Seventeen year old girl with mental confusion, delirium, spastic left hemiplegia and flaccid paralysis of the left shoulder girdle, recovered**

**History**—A B., a white girl aged 17 years, of Lithuanian parentage, was perfectly well until Aug. 17, 1935 when she noted that her eyelids were swollen and that the eyes were "bloodshot." This condition of the eyes lasted for about one week. No further symptoms were noted until August 27, when she complained of stiffness of the neck. August 30 she suddenly collapsed owing to weakness of the left leg and was put to bed, acutely ill with fever, nausea, vomiting, headache and pains in the back of the neck and in the lumbar region. August 31 she was delirious and mentally confused, and a flaccid paralysis of the left arm was noted. The family physician made a tentative diagnosis of acute anterior poliomyelitis and sent the patient to the contagious ward (South Department) of the Boston City Hospital September 2.

The patient was well developed and well nourished, and appeared to be acutely ill. She lay quietly in bed in a semi-stuporous condition but responded readily to questions. She was imperfectly oriented as to time and place and her memory for recent and remote events was impaired. There was incontinence of urine and feces. The vital signs were negative, as was the examination of the skin, ears, nose, throat, lungs, heart and abdomen. She was seen by us September 3 and was transferred to the neurologic unit. At that time the neurologic examination showed a slight weakness of the left lateral gaze, an impairment of convergence and upward and downward gaze and a moderately severe left hemiplegia of the cerebral type involving the leg arm and lower half of the face. In addition there was a complete flaccid paralysis of the muscles of the left shoulder girdle apparently of a lower motor neuron type. This flaccid paralysis was greatest in the scapular, the deltoid, the pectoral and the triceps muscles on the left. There was a moderate weakness of the biceps muscle and the muscles of the forearm, wrist and hand on the left. There were no subjective sensory symptoms, and no objective sensory changes were demonstrated. There was no tenderness of the muscles or of the nerve trunks. The biceps and triceps reflexes were absent on the left side and normally active on the right. The radial periosteal reflex was diminished on the left. The knee

9 Blumer George Tr. A. Am. Physicians 38: 189 1923

and ankle jerks were hyperactive on both sides, but more so on the left. There was a sustained ankle clonus on the left and an unsustained ankle clonus on the right. Babinski's toe sign was present on both sides, and no abdominal reflexes could be obtained.

**Laboratory Data**—The examination of the urine was negative. The blood count showed 4,000,000 red cells and 82 per cent hemoglobin. The white cells in the blood were counted daily between September 2 and September 14. The total count varied between 8,800 and 12,800 per cubic millimeter. Smears of the blood, which were stained with Wright's stain, contained between 0 and 44 per cent eosinophils. The first smear contained no eosinophils, the next two 6 per cent and 8 per cent, respectively. All subsequent smears contained more than 20 per cent eosinophils. The blood Kahn reaction was negative. Lumbar puncture on September 2 yielded a clear, colorless, cell-free fluid under a pressure of 180 mm of water. The colloidal gold and Wassermann tests were negative, and on chemical analysis the fluid contained 17 mg of protein, 54 mg of sugar and 719 mg of sodium chloride per hundred cubic centimeters. The lumbar puncture was repeated on September 6 and September 9. The condition in the fluid removed on these occasions was similar to that previously recorded. No trichinae were found in any of the fluids. The examination of the feces was negative. The electrocardiogram, September 13, showed a T wave with an abnormally low amplitude suggesting myocardial involvement. Biopsy of the left pectoral muscle showed an inflammatory and degenerative process. Many eosinophils were in the inflammatory exudate, but trichinae were not found in the small piece examined. The skin test for trichiniasis was positive, September 9 and 18. The electrical reaction of the muscles of the left arm was normal, September 10.

**Course**—There was a rapid improvement of the general condition, and five days after admission the patient was mentally clear and was continent of urine and feces. The weakness of the left arm gradually decreased, as did also the left hemiplegia. She was discharged from the hospital September 18 (sixteen days after admission), walking with a slight limp. The reflexes were still hyperactive in the left leg with ankle clonus and Babinski toe response. The strength of the left arm was almost normal and the reflexes in this arm were normal. She returned to the hospital at intervals for examination and when last seen, November 14, there was no motor deficit demonstrable. The reflexes in the left leg were exaggerated and the Babinski response was still present. The blood count at this time was normal except for an eosinophilia of 14 per cent.

The diagnosis in this case was established with considerable difficulty. Trichiniasis was suggested by the history of swollen eyelids and "bloodshot" eyes. Against this diagnosis at the time of admission, however, was the absence of muscle pains and the normal differential count of the blood, and the patient's mental condition was such that she did not remember having eaten any pork. The various diagnoses considered were poliomyelitis and encephalomyelitis. Acute anterior poliomyelitis was considered chiefly because the patient was admitted during a mild epidemic and because of the flaccid paralysis of the left shoulder girdle. This diagnosis was not thought tenable, however, because of the preponderance of cerebral symptoms and because of the normal cerebrospinal fluid. Acute encephalomyelitis, possibly in the nature of an acute multiple sclerosis, was thought to be the best diagnosis. In favor of it was the presence of signs indicating bilateral upper motor neuron and also lower motor neuron involvement. The occurrence of the edema of the eye and the conjunctival hemorrhages could not be explained on the basis of this diagnosis, however, and our attention was redirected to trichiniasis by the very high eosinophil count in subsequent blood smears. This diagnosis was confirmed by skin tests, by biopsy of the muscles and by the history of pork ingestion. When the patient became mentally

clear she remembered that on July 4 she and three friends had eaten pork patties at a local restaurant. The three friends were called in for examination. One of them had noticed on September 3 a slight swelling of his face, general malaise and stiffness of the neck. These symptoms lasted for two days. When examined September 12 the only positive finding was an eosinophilia of 40 per cent in the blood. The remaining two friends who had eaten the pork experienced no symptoms and showed no abnormality on examination September 13 except that their blood showed an eosinophilia of 8 per cent and 9 per cent respectively.

**CASE 2**—Girl aged 13 years with extreme muscular weakness and absent tendon reflexes, recovered.

**History**—S. K., a Negro girl, aged 13 years, was admitted to the First Medical Service of the Boston City Hospital June 17, 1934, and transferred to the neurologic unit June 19. Nine days before admission she noted a burning sensation in the eyes, which continued for three days. Six days before admission there was an attack in which everything went black before her eyes for about five minutes but there was no loss of consciousness. She was put to bed at once and on the following day she had pains in the thighs and arms. She was also nauseated and vomited a few times. Four days before admission a progressive weakness of the back muscles began to develop so that she was unable to sit up and there was also weakness of the legs and of the arms. Her voice became weak. Slight edema of the eyelids was noted twenty-four hours before admission, at which time her temperature was 101 F.

**Examination**—The patient was well developed and well nourished and was acutely ill. The examination of the head, neck, chest and abdomen was negative. The patient could raise her head from the pillow only slightly and she was unable to sit up. There was no stiffness of the neck or Kernig's sign. Blood pressure was 114 systolic, 80 diastolic. The cranial nerves were normal. She was able to move her arms and legs. There was considerable weakness of the thigh muscles and shoulder muscles. The extensors of the arm were weaker than the flexors and the quadriceps were the weakest of the thigh muscles. The deltoid triceps and extensor of the fingers on the left were weaker than on the right. All the tendon reflexes were absent in the arms and legs. Cutaneous and deep sensation was normal. The abdominal reflexes were absent. The plantar reflex was normal. No muscle or nerve tenderness was elicited.

**Laboratory Data**—The urine was normal. The blood Kahn reaction was negative. The blood count, June 18, showed a mild degree of secondary anemia and a leukocyte count of 10,600. No eosinophils were seen on the stained smears. June 20 the leukocyte count was 13,300 and the differential count showed 1 per cent eosinophils. June 21 the leukocyte count was 9,750 and the smear contained 25 per cent eosinophils. Smears stained at intervals between June 21 and the date of discharge, July 10, all showed eosinophils varying between 9 and 28 per cent. The chemical analysis of the blood showed 30 mg of nonprotein nitrogen and 82 mg of sugar per hundred cubic centimeters. The blood culture was sterile and the agglutination tests for typhoid, paratyphoid and *Brucella abortus* were negative. Electrocardiograms taken June 27, 30 and July 3 were negative. Lumbar punctures were performed June 18 and 20. The fluids were clear and colorless and under a normal pressure. The cell count was normal (1 and 3 cells per cubic millimeter). The globulin tests were negative and the protein content was normal. The colloidal gold and Wassermann reactions were negative. A skin test for trichiniasis was positive June 22, and biopsy of the deltoid muscle June 24 showed trichinae.

**Course**—There was a gradual improvement of the strength of the muscles so that by July 12 the patient was able to walk without difficulty. The ankle jerks could be obtained July 2 (fifteen days after entry) and the knee jerks were present on discharge. The blood showed an eosinophilia of 28 per cent at the time of discharge.

Trichiniasis was not considered at the onset of this case because of the absence of eosinophilia in the blood and because of the absence of the history of pork

ingestion. The diagnoses considered at this time were acute anterior poliomyelitis and polyneuritis. The widespread muscular weakness without any actual paralysis was against the diagnosis of acute anterior poliomyelitis, as was also the normal cerebrospinal fluid. The severity of the weakness of the trunk muscles, the absence of sensory loss and nerve tenderness were against the diagnosis of polyneuritis. The development of the marked degree of eosinophilia was the factor that directed our attention to trichiniasis. This diagnosis was confirmed by the skin test and by the finding of organisms in the muscles, although no history of pork ingestion could be obtained.

#### CLINICAL SYNDROMES

The involvement of the nervous system in trichiniasis may simulate polyneuritis, acute anterior poliomyelitis, encephalomyelitis and rarely meningitis. Cases presenting weakness of the muscles of the trunk and extremities with absent reflexes are the most common. The evidences in such cases vary from a complete paralysis with absent reflexes to an absence of reflexes without

absent reflexes. Stiffness of the neck was found in one of these eleven patients and in eight additional patients. Kernig's sign was present in two cases.

Cases presenting mental symptoms and focal neurologic signs have been reported by Salan and Schwartz,<sup>9</sup> Horlick and Bicknell,<sup>10</sup> Meyer,<sup>11</sup> Walker,<sup>12</sup> Gordon,<sup>13</sup> Bloch and Hassin,<sup>14</sup> Hassin and Diamond,<sup>15</sup> Pund and Mosteller,<sup>16</sup> Chasanow,<sup>1</sup> Sterling,<sup>17</sup> and Spink.<sup>18</sup> A summary of the clinical record of the fifteen cases presenting mental symptoms or focal signs is given in the accompanying table.

The occurrence of optic neuritis or cranial nerve paralysis has been noted by Chasanow,<sup>1</sup> Salan and Schwartz,<sup>9</sup> Spink,<sup>18</sup> Parker,<sup>19</sup> Thompson,<sup>20</sup> Stoll,<sup>21</sup> and Bosch.<sup>22</sup>

#### PATHOLOGY

Nine cases in which the nervous system was studied at necropsy are recorded in the literature. In the cases reported by Walker,<sup>12</sup> Gordon,<sup>13</sup> Knorr,<sup>23</sup> and Bloch and Hassin,<sup>14</sup> nonspecific changes were found, i. e. edema, congestion, mild infiltration and moderate nerve cell changes. Frothingham,<sup>24</sup> Gruber and Gamper,<sup>25</sup>

Summary of Cases of Trichiniasis Presenting Involvement of the Central Nervous System

Author	Age	Sex	Head ache	Stiff Neck	Delirium and Other Conditions	Focal Signs	Reflexes		Cerebro spinal Fluid	Outcome

muscular weakness. The degree of muscular weakness in our second case and in that reported by Chasanow<sup>1</sup> was so severe that the diagnosis of polyneuritis was seriously considered. Nonne and Hopfner<sup>2</sup> were the first to call attention to the fact that the deep reflexes may be absent in the course of trichiniasis. In six of twenty-seven cases they found bilateral absence and in five unilateral absence, since their report cases presenting absent reflexes have been recorded by Staubli,<sup>3</sup> Gaisbock,<sup>4</sup> Salzer,<sup>5</sup> Eisenhardt,<sup>6</sup> Schonborn,<sup>7</sup> Fuchs<sup>8</sup> and others. In an effort to determine the frequency of loss of reflexes in trichiniasis, we have reviewed the records of 110 cases that have been admitted to the Boston City Hospital in the past twenty years. The knee jerks were absent in eleven of the 110 cases, or 10 per cent. Several authors have emphasized the coincidence of stiffness of the neck, Kernig's sign and

Pund and Mosteller<sup>16</sup> and Hassin and Diamond<sup>15</sup> have reported cases in which they found nodules composed of glial, endothelial and hematogenous cells, and a trichina embryo. In the case reported by Gruber and Gamper,<sup>25</sup> in addition to the inflammatory nodules there were embolic lesions from a trichinous endocarditis.

Nonne and Hopfner<sup>2</sup> reported normal manifestations in the nerves and spinal cord of one patient in whom the reflexes were absent.

The pathologic mechanism of the production of neurologic symptoms in cases of trichiniasis are not all entirely clear. It can be readily understood how the inflammatory nodules in the brain and cord can produce symptoms, and it is also possible that small cerebral or meningeal vessels may be occluded by the organisms or by emboli from cardiac involvement and produce cranial nerve palsies and other focal signs. But the mechanism of the production of symptoms of generalized weakness and absent reflexes is not understood. It has been thought that these symptoms may be due to an involvement of the nerves by the trichinae or a toxin produced by them. This is supported by the finding of altered electrical reactions.<sup>20</sup> This theory has never been proved, however, since the only pathologic study<sup>2</sup> of the nerves was negative. It has been suggested that these symptoms may be due to the trichinous myositis. This is not a satisfactory explanation however since the reflexes are not lost so early in other forms of myositis.

#### CEREBROSPINAL FLUID

Trichinae have been found occasionally in the spinal fluid of patients with trichiniasis with or without nervous symptoms by Meyer,<sup>11</sup> Van Cott and Lintz,<sup>27</sup> Lintz,<sup>28</sup> Bloch,<sup>20</sup> Elliott,<sup>30</sup> Salzer<sup>\*</sup> and Cummins and Carson.<sup>31</sup> In addition, lymphocytes have been found in the fluids in several cases. Stoll<sup>21</sup> 90 and 92 per cubic millimeter, Fund and Mosteller,<sup>16</sup> 35 per cubic millimeter, Chasanow,<sup>1</sup> 11 per cubic millimeter, Meyer,<sup>11</sup> 50, 58 and 240 per cubic millimeter, and Gordon,<sup>13</sup> 30 per cubic millimeter.

We have examined the fluids from eleven patients with trichiniasis and the results were entirely within normal limits with regard to the pressure, cell counts, protein content, colloidal gold and Wassermann reaction. No embryos were found. Negative results are also reported by McDonald and Waddell<sup>32</sup> (thirteen cases) and others. It is perhaps worthy of note that the reports of the finding of trichinae in the fluids are chiefly in the older literature. In recent years, more reliance has been placed on the skin test and biopsy of the muscles, and the fluids are therefore probably not searched as carefully for organisms.

#### DIFFERENTIAL DIAGNOSIS

Cases of trichiniasis presenting neurologic complications must be differentiated from (1) polyneuritis, (2) poliomyelitis, (3) encephalitis or encephalomyelitis, (4) meningitis, (5) dermatomyositis and (6) periarthritis nodosa.

The diagnosis of trichiniasis can usually be established by the history of pork ingestion, by an eosinophilia in the blood (which may not develop until late, however), by the skin test and by biopsy of muscles. The cerebrospinal fluid is usually normal and helps to exclude poliomyelitis, encephalitis and meningitis.

Since skin lesions may be present in trichiniasis, the cases presenting muscular weakness may be confused

with dermatomyositis. It is differentiated, however, by the absence of widespread subcutaneous edema together with the history of pork ingestion, skin tests and biopsy.

Patients with periarthritis nodosa may have a polyneuritis with muscular weakness, absent reflexes and an eosinophilia in the blood.<sup>33</sup> The differential diagnosis in these cases depends on palpation of the arterial nodules or biopsy of them.

#### PROGNOSIS

The prognosis of the cases presenting only muscular weakness or absent reflexes is very good. The patients practically always recover with slight or no residual manifestations. The outlook is much more serious in the cases presenting mental symptoms or signs of focal lesions in the central nervous system, death occurring in six of the thirteen reported cases (46 per cent).

## EYE CHANGES IN HYPERTENSIVE TOXEMIA OF PREGNANCY

### A STUDY OF THREE HUNDRED CASES

ALTON V. HALLUM, M.D.

ATLANTA, GA.

During the past three years I have made rounds in the Negro obstetric ward of Grady Hospital twice weekly and made records of the fundus oculi of all patients whose systolic blood pressure exceeded 140 or whose diastolic blood pressure exceeded 90. This study was undertaken with the hope of possibly correlating the retinal picture with the degree of clinical toxemia.

The first change to be observed in mild toxemia is usually a generalized narrowing of the lumen of the arterioles, which may be limited to a single arteriole or one of its branches. Almost as frequently, however, the first change is a localized narrowing appearing as a single spasm or as a series of spasms, usually in the first half of the retinal artery. The fact that there is usually no associated exaggeration of arterial reflex and no arteriovenous compression suggests that the lesion is spastic and not sclerotic. If the location and degree of the constrictions vary at subsequent examinations, it is proof of their spastic nature.

The degree of arterial lesions, especially the generalized constriction, follows closely the degree of clinical toxemia. In the more marked toxemias there is a combination of spasms and generalized constriction. Retinal edema usually first becomes visible near the upper and lower margins of the disk and radiates along the course of the retinal vessels. Retinitis, as shown by hemorrhages and exudates, is most often seen in the posterior third of the retina.

The arterioles may regain their normal caliber if there is a reduction of the blood pressure to normal sufficiently early. Wagener<sup>1</sup> states that if the lesions exist as long as ten days they have probably become sclerotic although they were originally angiospastic. Milius (according to Bergmann<sup>2</sup>), who made histologic examinations of the eyes of women who died in eclampsia, concluded that spastic changes in the retinal

vessels might exist for many weeks without producing organic changes. Bergmann stressed that the degree of spasticity might vary in direct ratio with variations in the blood pressure.

Silex<sup>3</sup> as early as 1895 stated that in cases of retinitis with definite vessel changes the prognosis was worse. Mjlius (quoted by Freeman<sup>4</sup>) in 1928 described spastic changes in the arterioles that he proved conclusively by fundus photographs. He showed that the changes in the arterioles preceded the retinitis and were the local cause of retinitis.

Wagener<sup>5</sup> in 1933 reported the study of a series of forty cases of hypertensive toxemia of pregnancy and concluded that spastic lesions of the arterioles were the most frequent and usually the primary sign of retinal involvement. They occurred in about 70 per cent of his cases, about 60 per cent of the spastic lesions disappeared with the termination of pregnancy and the return of the blood pressure to normal. In about 40 per cent of the cases organic lesions developed in the arterioles often with retinitis, and in such cases elevation of the blood pressure usually persisted. He considered diffuse retinitis of the albuminuric type as evidence of severe generalized arteriosclerosis rather than of nephritis. In a later paper he<sup>6</sup> stated his belief that the majority of these patients with retinitis would have persistent hypertension, since he showed by biopsy and at necropsy that the arterioles through the body were permanently damaged. It was logical for him to conclude that the development of retinitis in any case of toxemia of pregnancy was a serious menace to the future integrity of the vascular system of the mother and an urgent indication to terminate pregnancy. The series that I am reporting substantiates his conclusions.

Wagener, Schiotz and Masters have noted that when retinitis developed before the twenty-eighth week there was only about a 25 per cent chance of the patient giving birth to a living baby, even if pregnancy was continued to the stage of viability, and there was almost 100 per cent risk of permanent cardiovascular-renal injury developing. I have seen five patients with retinitis before the twenty-eighth week, only one, or 20 per cent, gave birth to a living baby. Three of these patients had exhibited hypertensive toxemia previously.

However, if the toxemia that precedes the twenty-eighth week is not accompanied by retinitis, the chance for a live baby is not much better. I have seen twenty-one patients, all of whom had moderate to severe hypertension and arterial changes without retinitis, of these only six, or 29 per cent, gave birth to living babies. In eighteen labor was induced artificially, if the pregnancies had been allowed to continue to the period of viability, the mortality rate would undoubtedly have been higher. In thirteen of these cases there had been previous pregnancies with hypertensive toxemia, with eclampsia in two cases. The average age was 30 years, and the parity varied from one to twelve.

In fifty-three cases of this series there was a record of a previous hypertensive toxemia of pregnancy. It is interesting to study the effect of the previous toxemia on a subsequent pregnancy. The average age in this group was 30.2 years. In 77.4 per cent there were vascular changes and in 9.4 per cent retinitis. In seven,

or 13.2 per cent, the fundus oculi was normal. Forty, or 75.5 per cent, of the babies were born alive. One hundred consecutive patients without previous hypertension or hypertensive toxemia of pregnancy were studied for comparison. Their average age was 24.2 years, and 91 per cent of the babies were born alive. Seventy-eight per cent showed arterial changes, and 12 per cent retinitis. Seventeen per cent had normal fundi. Wagener expressed the opinion that the presence of previously established organic changes in the retinal arterioles was not of itself a contraindication to a future pregnancy, in fact, his group of patients with previous hypertension showed fewer angiospastic changes than did another group of patients without previous hypertension, and the control group showed a higher incidence of retinitis. In my series if the cases with arterial changes together with retinal edema were classed as retinitis, the group with previous hypertensive toxemia of pregnancy would show a higher percentage of retinitis than would the group without previous hypertensive toxemia of pregnancy. Also, since nephritis and severe grades of hypertension are more frequent in those patients who have had a previous toxemia, I would conclude that one hypertensive toxemia of pregnancy contraindicates another pregnancy because the patient is more likely to suffer permanent cardiovascular-renal damage.

Urinalysis had been done on 280 of these patients and the general trend of the albuminuria fairly closely followed the severity of the hypertension and the occurrence of retinitis. But the absence of albuminuria agrees with Curtis,<sup>7</sup> who said that a rise in blood pressure might occur and persist throughout pregnancy without apparent evidence of renal disease. Forty-one per cent of the patients showed no albuminuria, even in class 3 (severe) hypertension there was no albuminuria in 32 per cent, and only a trace in 14 per cent. However, as the albuminuria increased from 1 plus to 4 plus there was proportionate increase in the frequency of fundus changes, especially retinitis, and also a proportionate increase in the frequency of eclampsia and class 3 hypertension. It seems then that the absence of albuminuria in these patients is without great significance, but a high grade of albuminuria indicates a severe grade of toxemia. This is likewise true of the presence of casts in the urine.

The phenolsulfonphthalein urinary and the non-protein nitrogen, creatinine and sugar content of the blood did not show changes in keeping with the degree of clinical toxemia.

Excessive gain in weight was exhibited by forty patients, that is, 10 pounds or more within a month, and in all cases this gain occurred during the last trimester. The fact that the average was 23.3 years, that only seven, or 17.5 per cent, had been pregnant more than five times (50 per cent were primiparas) and that thirty-nine, or 97.5 per cent, of the babies were born alive indicates that this unusual weight gain is not usually associated with an extremely severe toxemia. Only three, or 7.5 per cent, showed retinitis.

When the patients are classified (table 1) according to the severity of the hypertension, one sees the most striking increase in the frequency of eye changes on passing from class 1 to class 2 hypertension. Eye changes occur in 40.8 per cent of class 1, in 84.5 per cent of class 2 and in 98 per cent of class 3. Class 1 included those patients whose blood pressure did not

<sup>3</sup> Silex, quoted by Wagener<sup>6</sup>.

<sup>4</sup> Mjlius, K., quoted by Freeman, David, Retinal Angiospasm, Baltimore City Medical Society, Section of Ophthalmology, Dec. 7, 1932, Am. J. Ophthalmol. 16:3-1 (April) 1931.

<sup>5</sup> Wagener, H. P., Arterioles in Toxemia of Pregnancy, J. A. M. A. 101:140 (Oct. 28) 1933.

<sup>6</sup> Wagener, H. P., Lesions of the Optic Nerve and Retina in Pregnancy, J. A. M. A. 103:1910-1913 (Dec. 22) 1934.

<sup>7</sup> Curtis, A. H., Obstetrics and Gynecology, Philadelphia, W. B. Saunders Company, 1:1027, 1933.

exceed 150/100 before delivery, likewise, class 2 included those patients whose blood pressure ranged from 150/100 to 175/125, and class 3 included those whose blood pressure exceeded 175/125. The blood pressure range was determined by the variations over a period of several days or weeks. Thus it was seen that 53.3 per cent of the retinitis fell into class 3 and only 3.3 per cent fell into class 1, and 32.7 per cent of the patients in class 3 showed retinitis, whereas only 3.7 per cent of those in class 1 showed retinitis. Likewise fifteen cases, or 78.9 per cent, of the eclampsias occurred in class 2 and the remaining four, or 21.1 per cent, occurred in class 3.

When the patients were studied grouped according to the type of toxemia it was found that there was some ocular fundus change in 62.1 per cent (retinitis in 9.5 per cent) of the preeclamptic patients, in 84.0 per cent (retinitis in 11.6 per cent) of the nephritic patients and in 95.2 per cent (retinitis in 45.0 per cent) of the eclamptic patients. Thus it is quite certain that permanent damage is done to the mother's vascular-renal system by all three types of toxemia.

In this series of 300 patients 76.3 per cent showed abnormalities of the fundus oculi (table 2). The changes were classed as only arterial in 62.5 per cent and as retinitis in 13.2 per cent. The average age of the 300 patients was 25.3 years, whereas those who showed pathologic conditions averaged 26.2 years and those without such conditions averaged 21.8 years. The age increased from 23 years average in class 1 to 30.2 years in class 3. The twenty-one eclamptic women averaged 21 years of age, fifteen were primiparas and averaged 18.5 years of age, while the six multiparas with eclampsia averaged 27.5 years of age. Labor was induced on 108 patients, on thirty, or 60 per cent, of the patients with class 3 hypertension, and on fourteen, or 66.7 per cent, of the patients with eclampsia.

The maternal mortality in this series of 300 patients was two, or 0.07 per cent. Both patients were primip-

Retinal detachment is an infrequent complication in toxemias of pregnancy. In six cases, or 2 per cent, of this series bilateral detachment developed before delivery. All patients showed retinal arterial changes and diffuse retinitis, indicating that the type of toxemia was severe in each case. Vision was markedly impaired in each instance, but all improved rapidly as the retinas were completely reattached within ten days after

TABLE 2—Hypertensive Toxemia of Pregnancy in 300 Cases

	(300)		Average Age (25.2)	Labor Induced (108)	
	Number	Per Cent		Number	Per Cent
Any eye change	229	76.3	26.2	91	84.3

\* Without eye changes 21.8

delivery of the baby. The average age of the mothers was 21 years, five were primiparas, and the other two were secundiparas. Only three gave birth to living babies. Three were classed as eclamptic. Two had class 2 hypertension and four had class 3 hypertension, all of which indicated that a severe toxemia was present in each.

#### CONCLUSIONS

1 The ophthalmoscope, I think, should be rated next to the sphygmomanometer as an instrument of diagnostic importance in the management of a case of hypertensive toxemia of pregnancy.

2 Generalized narrowing and localized spastic constriction of the retinal arterioles are the earliest changes in the fundus oculi, retinal edema, hemorrhages and exudates appear later if the toxemia progresses in severity.

3 When hypertension develops or increases during pregnancy, careful watch should be kept for angiospastic lesions of the retinal arterioles. Pregnancy should be terminated if the progress of these lesions cannot be controlled by conservative measures, and certainly before the onset of retinitis.

4 The arterioles may regain their normal caliber if there is a sufficiently early reduction of the blood pressure to normal.

5 The frequency and degree of lesions of the fundus oculi closely follow the severity of the hypertension.

6 If retinitis occurs before the twenty-eighth week of pregnancy there is only about a 25 per cent chance of the patient giving birth to a living baby, even if pregnancy is continued to the stage of viability, and there is almost 100 per cent chance of permanent vascular-renal injury developing. If toxemia precedes the twenty-eighth week of pregnancy and is not accompanied by retinitis, the prognosis is slightly better.

7 A previous hypertensive toxemia of pregnancy contraindicates a future pregnancy; the chance of the patient developing eclampsia is less, but the prospect of a live baby is not as good, and the chance of developing permanent vascular-renal injury is greater.

8 Retinal detachment occurs in about 2 per cent of hypertensive toxemias of pregnancy. The detachments usually become reattached within ten days after termination of the pregnancy.

paras and both were eclamptic. Their ages were 38 and 18 and there was no history of previous hypertension. In these cases labor was induced during the eighth and seventh months of pregnancy. The older patient gave birth to a living baby, and the younger patient died before the baby was delivered. The older patient showed rather marked arterial changes and diffuse retinitis before death, but the younger patient was lost seen eight days before the onset of convulsions and ten days before death, and at that time she showed marked constriction of the entire tree of the retinal artery, and variations in caliber of almost every arterial branch.

## TRICHLOROETHYLENE INTOXICATION

HERBERT EICHERT, MD

BALTIMORE

Since 1915, when Oppenheim recommended trichloroethylene as a therapeutic agent, numerous investigators have published contradictory opinions regarding the efficacy of the drug to relieve the pain of trigeminal neuralgia. Reports of beneficial results following the use of the drug range from 85 per cent complete relief, as reported by Plessner,<sup>1</sup> to only 5 per cent complete relief, as reported by Seelert<sup>2</sup> in a later paper. More recently the drug has been used with some success as a hypalgescic in the treatment of angina pectoris.<sup>3</sup> The further clinical applicability of the drug has been investigated by Striker and his associates,<sup>4</sup> who have successfully employed it to induce general anesthesia during surgical operations. The clinical observations of these investigators, together with the published results of laboratory studies of the effect of the purified drug on laboratory animals, have led to the general feeling that the relatively pure drug is without harmful effects unless massive overdoses are administered.<sup>5</sup> After observing more than 300 cases of anesthesia produced by trichloroethylene, Striker and his associates concluded that "pure trichloroethylene has no harmful effects when properly inhaled in such quantities as are required to produce analgesia and anesthesia." Herzberg<sup>6</sup> reported that the liver, spleen, kidneys, diaphragm, pancreas, heart muscle, lungs, adrenals and pectoral muscles taken from three dogs that were killed by an overdosage of trichloroethylene after being deeply anesthetized with the drug for periods ranging from two and one-half to three and one-half hours showed no gross or microscopic changes. Joachimoglu<sup>7</sup> obtained similar results, indicating that the drug does not cause demonstrable pathologic changes.

On the other hand, the industrial utilization of this chemical has resulted in numerous instances of poisoning, and the literature is replete with instances of such accidents. Alice Hamilton<sup>8</sup> has reviewed the cases of industrial poisoning due to trichloroethylene and mentions 284 cases with twenty-six deaths. As against this impressive toxicity exhibited by the drug in industry, there are few reported instances of toxic symptoms in which the drug has been used therapeutically. Some have expressed the opinion that this difference in the appearance of toxic symptoms has been caused by the presence of adventitious substances and decomposition products present in the relatively impure commercial products. On this point, Glaser<sup>9</sup> has expressed the opinion that "it certainly appears as if the present trichloroethylene is not the drug responsible for the toxic symptoms mentioned in Plessner's workers." Various other writers have ascribed this difference in action to the length of time during which the drug was inhaled or to the amount of it that was ingested.

Because of the paucity of observations following prolonged administration of large doses, further con-

fusion exists concerning the clinical effects of trichloroethylene. The official comment in New and Non-Patented Remedies states that the actions of trichloroethylene have not been investigated comprehensively, and that it was introduced in therapeutics following some observations on man. As a matter of fact, although there are more than 280 cases of industrial poisoning with trichloroethylene reported in the literature, there is only one reported case of severe intoxication following the accidental and improper use of therapeutic trichloroethylene.

The salient features that this lone case presented are as follows:<sup>10</sup>

A woman, aged 34, had a history of chronic addiction to morphine and ether and of a successful treatment of that condition. A dental neuralgia developed and her dentist prescribed trichloroethylene to allay the pain. After the need for the remedy had disappeared she continued to take the drug and finally increased the amount until she was taking 50 Gm a day. The symptoms that developed resembled those of "narcotism" and included tremor, nausea, reduced will power and marked emotionalism with mild delirium. Recovery followed promptly after withdrawal of the offending drug.

During the past year two similar instances of the malign effects of prolonged trichloroethylene overdosage have been observed in the Johns Hopkins Hospital.

The first patient was admitted to the private wards. Since it was impossible for the patient to give any history at the time of his admission, the following data were obtained from his family:

CASE 1—A retired business executive, aged 52 had led a very tense and active life. His habits, in general, were normal. Alcohol was used occasionally in moderation. Three years before the time of admission he began to have pain in the right side of the face. Initially it was thought that the pain was of dental origin and therefore two of his teeth were extracted, but the symptoms persisted. After a time the character of the pain indicated its nature and a diagnosis of trigeminal neuralgia was made. There were periods of several consecutive months during which there was no discomfort, but in spite of various treatments it recurred invariably. Two years before he came to the hospital he began to use a proprietary preparation of trichloroethylene prescribed by his physician. He gradually increased the dose inhaled. About ten days before admission pains developed in the shoulders, elbows, legs and knee which were attributed to a "grippal attack," although the usual symptoms of such an infection were lacking. He increased the dosage of trichloroethylene until he began to be drowsy and listless. It is known that he continued to take the drug until he was admitted, although no accurate information was available concerning the amount consumed, it was said that he used a full bottle (about 4 ounces, or 120 cc) during the two days before he was admitted to the ward. During this period he developed a "thickness of speech," difficulty in concentrating and a marked tendency to "grope for words." He became very unsteady while standing, and his wife stated that he appeared as though he were drunk. The mental disturbances became progressively more marked.

On admission to the hospital the first impression of the house staff was that the patient was in a catatonic stupor. He could hardly stand without assistance, appeared very drowsy and manifested a tendency to lapse into sleep if left alone, and his movements were sluggish and inaccurate. There were evidences of moderate loss of weight, but no other physical abnormalities were noted. Since the patient was unable to cooperate the neurologic examination was of necessity incomplete, but objectively there were no neurologic changes. A psychiatric consultation was requested and it was the opinion of the psychiatrist that a concentration difficulty was the essential feature. The patient was disoriented for time and place and very confused. There was a moderate degree of aphasia and dysarthria.

Diagnostic possibilities suggested by this clinical picture included epidemic encephalitis and bromide intoxication. A lumbar puncture yielded spinal fluid which was determined to be normal and examination of the urine failed to disclose the presence of bromides. The administration of trichloroethylene was discontinued immediately and the patient improved rapidly. Within three days his mental clarity was restored almost completely. At this time he complained of numbness of the face, but there was no anesthesia of the area innervated by the trigeminal nerves. Coincident with the return of normal mental reactions the patient complained of slight pain in the right side of the face, but this symptom was readily relieved by small and infrequent doses of acetylsalicylic acid. His convalescence was rapid and uninterrupted. No specific therapy was employed. At the end of two weeks his mental acuity had returned completely and no psychologic defects were noted. There was some residual nervousness and weakness and a moderate degree of manition which disappeared after several weeks of rest and roborant measures. A communication from the patient, eight months after he had left Baltimore indicated that there were no aftermaths of his illness.

CASE 2—A woman, aged 52, came to the outpatient department because of pain in the right lower part of the jaw and tongue. Trichloroethylene was prescribed but as this failed to relieve the pain a partial section of the fifth nerve root at the level of the pons was performed. The operation did not have the desired result, for the pain persisted. Pending the day on which a second operation was to be done trichloroethylene was prescribed again in doses of 20 drops three times a day. The details of the immediate sequence of events were never revealed, but it is known that the patient succeeded in obtaining a large quantity through the wholesaler and that she took increasing amounts of it on a handkerchief and inhaled it repeatedly. Over a period of several days she is said to have used about 6 ounces (180 cc). A fulminating psychosis developed with acute hallucinations and a striking change of personality. The patient had been a composed and temperate individual on this occasion she is said to have come downstairs to dinner, seated herself at the table and commenced to devour a ham. Attempts by the family to control the bulimia were thwarted by the patient's strange behavior. At their approach she would desist from her depredations, scowl at her kinsmen and reply to their remonstrations by growling and making queer noises. So successful were her intimidating gestures that she was able to hold them at bay until she had gormandized the whole ham. Then she half-walked, half-crawled up the stairs and, having reached the top attempted to stand up but fell backward and down the stairs and fractured one of the lumbar vertebrae. She was brought to the hospital, where a suitable cast was applied. The bizarre symptoms that she had manifested prior to her admission disappeared rapidly after the administration of the trichloroethylene was stopped. At no time during this period of observation did she complain of pain in her face and subsequent reports received several months later, indicated that the pain had not recurred, nor were there any residual effects noted which might have been in any way attributable to the overdosage of trichloroethylene.

Most of the symptoms noted have been observed also following the industrial use of trichloroethylene. In addition, trichloroethylene as used industrially is capable of provoking symptoms that have not been observed following the use of therapeutic trichloroethylene. For purposes of comparison, certain outstanding effects ascribed to the use of industrial trichloroethylene are listed below.<sup>8</sup> Particular attention is called to the fact that none of the symptoms listed here have ever been observed following the use of therapeutic trichloroethylene.

The effects are

- Cerebral manifestations pointing to lesions in the capillary walls
- Epileptoid seizures
- Corneal anesthesia and painless keratitis
- Swelling of the optic disk

Optic neuritis

Optic atrophy with blindness

Anesthesia in the area innervated by the trigeminal nerve

Paralysis of the fifth nerve persistent after seven months

Trophic changes leading to the loss of teeth

Persistent auditory dysfunction

Progressive loss of speech

Many writers have noted a difference in the general effects of the chemical depending on whether it was absorbed accidentally in industry or as a result of therapeutic administration. The difference in effect has been variously attributed to (1) the presence of adventitious substances in the industrial trichloroethylene, (2) the length of time of administration, (3) the amount inhaled or (4) a combination of these several factors. Striker expresses the opinion that the pathologic manifestations noted in industrial cases were due to contaminations in the trichloroethylene or more likely to some other causes. Prior to the observations reported in this article there were no reported cases to indicate what the effects of large amounts of therapeutic trichloroethylene inhaled over relatively long periods of time might be. The failure of these cases of intoxication following large and prolonged dosage of the chemical to evince any of the graver symptoms attributed to industrial trichloroethylene poisoning tends to emphasize the suggestion made by the earlier investigators, i. e., that the toxic effects noted among the industrial workers may have been attributable, in some measure at least, to adventitious substances or decomposition products of trichloroethylene. On this point a significant inference may be drawn from the fact that, although there followed grave sequelae in the industrial cases, the symptoms that occurred in the clinical intoxications were ephemeral and disappeared promptly after withdrawal of the drug. Striker emphasized this opinion when he concluded that after general anesthesia with trichloroethylene there is a notable absence of postoperative nausea, vomiting, depression and the like. Perhaps one of the most significant observations in establishing the difference between the effects of therapeutic and uncontrolled industrial absorption of trichloroethylene is the fact that although in industrial cases facial anesthesia and abolition of the corneal reflex were not infrequent, these effects were never observed in any patient who had received trichloroethylene therapeutically, unless a sufficient amount of the drug had been given to induce general anesthesia.

#### SUMMARY

1 Many cases of industrial poisoning with trichloroethylene have been reported, but there is only one recorded instance of a toxic syndrome following the prolonged therapeutic administration of the chemical. Two additional cases are presented here.

2 The symptoms observed in the latter group were due to a disturbance of the central nervous system as manifested by mental confusion, disorientation, inability to concentrate, amnesia, aphasia, dysarthria, ataxia and analgesia without anesthesia of the area innervated by the trigeminal nerve.

3 In view of these observations it seems likely that the original supposition is correct, namely, that the cases of industrial poisoning were due partly to adventitious substances and that all the manifestations noted in the industrial cases of so-called trichloroethylene poisoning were not necessarily effects of trichloroethylene per se.

4 Although proprietary preparations of trichloroethylene are thought to be relatively harmless remedies if used in prescribed amounts, the cases presented here indicate that this therapeutic agent is capable of producing grave states of intoxication if the suggested dosage is exceeded or if the administration of the drug is unduly prolonged

## EFFECT OF INJECTION OF BACTERIAL FILTRATE ON BROWN-PEARCE RABBIT EPITHELIOMA

W T POMMERENKE, MD

ROCHESTER, N Y

The employment of bacteria or their products in the treatment of malignant disease is not new. One need only refer to the work of Coley,<sup>1</sup> who for some forty-five years has reported favorably on the use of bacterial preparations in certain neoplasms. More recently Beebe and Tracy<sup>2</sup> were able to observe regression and disappearance of transplanted tumors in dogs that had been given injections of bacterial filtrates. Complete destruction of a transplantable mouse tumor was produced by Shear<sup>3</sup> in a high percentage of cases with filtrates of *Bacillus coli*. It is not my purpose here to review the rather extensive literature that has accrued on this general subject. However, reference must be made to the recent publication of Connell,<sup>4</sup> since it instigated the present study. Connell reported that symptoms of some patients suffering with carcinoma could be ameliorated by the administration of certain bacterial filtrates containing enzymes, which he calls "Ensols." These Ensols Connell prepared by inoculating with *B. histolyticus* a tube containing cancer tissue immersed in physiologic solution of sodium chloride. The cultures were incubated anaerobically at 37.5 C. for from four to six days, during which time the cancer tissue was digested presumably by ferments generated by the bacteria and specific for the type of cancer protein provided in the medium. The sterile filtrate obtained by passing the fluid through a Berkefeld candle was found to produce "much more rapid lysis of the cancer cells than took place in control tubes undergoing sterile autolysis." According to Connell's statements, clinical improvement of certain patients having carcinoma resulted from the injection of these Ensols. The growth of visible tumors was checked with softening and absorption. Patients having pain as a prominent symptom obtained relief with Ensol and were enabled to get along with a diminished dosage of sedatives. As far as is known to me, Gye<sup>5</sup> is the only one to have published subsequently experiments similar to those of Connell. He was unable to observe any effect of the injections of Ensol on the growth of mouse tumors.

Because of obvious restrictions incidental to the use of human material, the present study was undertaken

on animals, in the hope thereby of gaining accurate experimental information on the mode of action and on the effects of similar bacterial filtrates. The Brown Pearce rabbit epithelioma of the testicle would appear to be a particularly suitable test tumor and was used in these experiments. Its genealogy and biologic behavior are well known. It is a highly malignant animal tumor which, unchecked, runs a rapidly fatal course in a large proportion of cases.

### METHOD

*Inoculation of Animals*—Unless recorded to the contrary, the tumor tissue used for inoculation and for the preparation of the bacterial filtrate was obtained from nontreated and otherwise normal rabbits. This viable tumor tissue was removed either from the primary tumor growth or from a metastatic nodule. Tissue from one to four representative regions of the tumor mass was prepared for microscopic examination. Other tissue from the same region was minced with scissors until the individual particles were about the size of wheat grains. These were handled under aseptic precautions throughout and introduced with a trocar into the central portion of the testis, two or three such particles being inoculated into each rabbit. This is the standardized technic employed for more than three years in the division of radiology<sup>6</sup> and has been used in the inoculation of more than 1,000 rabbits. The rabbits in this series which had received such tumor inoculations were divided into two almost equal groups, one half receiving the bacterial filtrate, the other serving as controls.

*Preparation of the Bacterial Filtrate*—The bacterial filtrate was prepared according to the directions of Connell for the production of Ensol. Masses of tumor tissue were removed aseptically from rabbits anesthetized with ether. As much as possible of the adjacent tissue, either from the site of the primary tumor or from a metastatic nodule, was carefully dissected away, so that the remaining tissue was quite homogeneous, thus fulfilling the supposed requirement that only one type of protein be present in the medium. This tumor tissue, which was of the same type as that used for inoculation of other rabbits, was then immersed in physiologic solution of sodium chloride, the proportion of tissue to the solution being approximately 1:10. After the mediums were inoculated with *B. histolyticus*,<sup>7</sup> the culture was rendered anaerobic with a layer of sterile petrolatum and incubated at 37.5 C. for from five to eight days. During this time lysis of the tissue could be readily observed. Fibrous tissue and other undigested residue settled out. The supernatant fluid was passed through a Berkefeld candle, and the filtrate, after having passed the test of sterility in this final form, was now ready for injection. It will be noted that this filtrate was prepared without exception from the precise type of tumor tissue with which the rabbits were inoculated. Furthermore, rabbits 78 and 81 received injections of filtrate prepared from tumor tissue removed from their own bodies. A sizable colony of rabbits with tumor was available to supply tissue for fresh filtrate. At no time was the filtrate more than 16 days old when injected.

*Injection of Filtrate and Further Care of Animals*—Preliminary injections of 0.2 cc of the filtrate were

given under the skin of the ear to determine possible toxicity or other deleterious effect. It was soon learned that rabbits could tolerate with impunity dosages as large as 4 cc given intravenously or subcutaneously. Larger doses were not given and it is believed that no untoward effects have immediately followed any of the injections. The usual procedure was to inject the rabbits daily, the intravenous and subcutaneous routes being used on alternate days. The routine dosage was 0.6 cc. The rabbits were kept in individual cages and received a diet of oats, cabbage and alfalfa. Tap water was provided ad libitum. Aside from the matter of injections of the filtrate, the controls received the same

night. However, in all cases autopsies were promptly performed. The tissues were preserved in Zenker's fixative and stained with the usual hematoxylin and eosin. We were thus enabled to accumulate a fairly complete series of slides of tissues coming from the control and the injected groups, as well as in cases in which biopsies were taken from the same animals before and after treatment.

## EXPERIMENTAL STUDY

The almost invariable finding that variation is the rule in biologic response certainly must be regarded in the interpretation of phenomena pertaining to cancer.

TABLE 1—Effect of Injections of Filtrate on Rabbits Previously Inoculated with Tumor Coming from Untreated Hosts\*

\* In the E group, tumor coming from untreated hosts was transferred to rabbits having had preliminary or prophylactic injections of the filtrate. Injections were then continued to date or until the animals died.

treatment as did the experimental animals. The animals were periodically weighed, the weights being considered an index of their general condition. At frequent intervals calipers were used to measure the rate of growth of the primary tumor, graphic records being kept. Note was also made of the appearance and growth of metastases. When in the course of events, both in the treated and in the untreated group, cachexia supervened as a result of the malignant growth and it appeared that the animal would in all probability die within a few hours, the animal would be killed, so that fresh tissue might be available for microscopic study. When this occurred, the term "killed—extremis" was applied in the accompanying tables. Even with this precaution, an animal would occasionally die during the

growth and destruction. Innate resistance to cancer is probably not constant in different individuals or animals. Numerous factors doubtless determine whether or not a fragment of cancer tissue will take root and thrive within a new host. The behavior of a large number of transplants of cancer will have to be observed before an entirely satisfactory basal or standard response can be determined or anticipated. But even allowing for these variables I believe that the present series of experiments will permit of certain deductions. Only a portion of the observations lend themselves to statistical treatment. Primarily for convenience, however, pertinent data have been arranged in tabular form. As criteria for the determination of the effects of injection of the bacterial filtrate on the

growth of the Brown-Pearce rabbit epithelioma, the following were used

- 1 The percentage of takes
- 2 The rate of growth of the primary tumor
- 3 The development of metastases
- 4 The regression or disappearance of the tumor
- 5 The longevity of the animal after inoculation with tumor
- 6 The microscopic appearance of the tissue

Table 1 summarizes the first experiment. Injections of filtrate were started on the seventeenth, fourteenth and thirteenth days following the inoculation of three groups of rabbits with the tumor fragments. Rabbit 76 appeared to be immune to this tumor, since four attempts at establishing the tumor transplants were unsuccessful. Rabbit 78 was originally selected as a

venous and subcutaneous injections of filtrate. After this the rabbits were given inoculations with the tumor taken from untreated animals having actively growing tumor. Subsequent injections also were given, the total number of injections being indicated in the table. The results in group D may well be thrown out. The tumor transplants coming from rabbit 75 apparently fell on uninfertile soil, as rabbits 76 and 82 have repeatedly shown themselves to be immune. In group E, however, it will be noted that the span of life of the rabbits receiving the injections was not prolonged.

Another experiment consisted of inoculating three rabbits with tumor from a rabbit that had received injections of filtrate on the preceding eight days. No further treatment was given these three animals. The

TABLE 3—Experiment 3 \*

	Rabbit Supplying Tumor	Number of Injections of Filtrate to Rabbit Supplying Tumor	Rabbit Receiving Tumor	Injections Given to Rabbit Receiving Tumor		Longevity After Inoculation with Tumor Days	Comment
				Before Inoculation with Tumor	Total Number of Injections

	90	10	71	207	19	45	26	Died of tumor metastases
Control	90	10	71	211			70	Living (?) Immune
	90	10	71	212			70	Living tumor growing
	90	10	71	213			62	Died of tumor metastases

\* In the experiment tabulated here three rabbits which had received prophylactic injections of filtrate were inoculated with tumor taken from a rabbit which had had ten prophylactic injections and sixty-one subsequent injections. Injections into the three rabbits were continued to date or until death of the animals.

control. However, when the tumor growth was 77 days old and metastases were noted in the pelvis, the primary tumor was removed and the rabbit then given injections. Eight injections of filtrate prepared from this rabbit's own tumor apparently did not materially alter the fatal course of the disease. In group B the tumor growth in rabbit 80 had become apparently static. The animal remained in good clinical condition after 138 injections of filtrate, even though metastatic nodules persist. The primary tumor has diminished somewhat in size but still persists. Rabbit 81, which as rabbit 78 originally served as a control, received eight injections of an isofiltrate without apparent effect. Control rabbit 82 in this group is apparently immune to this type of tumor, since he withstood four attempts at establishment of the tumor. When one compares the longevity of the rabbits in the three groups of experiment 1, it is apparent that the injected animals did not seem to possess a striking advantage over the controls.

In experiment 2 (table 2) a group of rabbits was given a 'prophylactic' or preliminary course of intra-

transplants of tumor took in every case. Today, seventy-one days following the inoculation, two rabbits are showing progressive cachexia. In the third rabbit the tumor growth is apparently arrested or is perhaps even regressing, although the primary tumor still measures 3 by 2.5 by 0.5 cm in its various diameters.

In experiment 3 (table 3) tumor tissue was removed from rabbits that had just received a course of treatment consisting of daily injections (forty-one and thirty-one) of filtrate. This tissue was immediately transplanted to two other groups of rabbits, which had then just completed a course of preliminary or prophylactic injections of filtrate. The injections were then continued without interruption to date or until the animals died. Examination of table 3 shows that the length of life or condition of the rabbits was not significantly altered by the injections.

In experiment 4 (table 4) ten preliminary or 'prophylactic' injections of the bacterial filtrate were given to rabbit 90 on the days immediately preceding inoculation with tumor. On the sixty-one days following the

inoculation with tumor the injections were continued the rabbit receiving in all seventy-one injections. Tumor fragments from this rabbit were now transplanted into six rabbits. Three of these, rabbits 205, 206 and 207, had by this time already received nineteen prophylactic injections. The injections of filtrate into these three rabbits were continued to date or until the death of the animal. At present four of the six rabbits in this group are living. In two of the treated rabbits the tumors and metastases are apparently still growing. One treated animal died on the twenty-sixth day following inoculation with tumor. In the control group one rabbit died of tumor metastases on the sixty-second day. Examination of table 4 will show that no apparent protection was conferred on the rabbits receiving the filtrate.

In experiment 5 the tumor was first passed through two hosts that had received injections of the filtrate before and after the inoculation with tumor. The first of these, rabbit 90, had received ten prophylactic injections and sixty-one injections after the inoculation with tumor. Tissue from this rabbit was then transplanted into rabbit 207, which by this time already had received nineteen prophylactic injections. Injections were continued in this rabbit, twenty-six more being given

is by extension along the spermatic cord to the pelvis. Metastatic nodules are frequently found in the retroperitoneal and omental glands. The kidneys were secondarily involved in a large percentage of cases. Metastases were also commonly found in the liver, spleen, lungs and mediastinum. Less often they are found under the skin or in the eyes. The abdominal and renal metastatic tumors are readily palpable in the living animal. Frequently the larger tumors become necrotic in their centers presumably because of inadequate blood supply. Special pains were taken to observe whether more necrosis occurred in the treated or in the nontreated groups of animals. No constant difference could be found. Microscopic preparations likewise failed to reveal any recognizable and characteristic morphologic changes as a result of the injections. In no case did the microscopic picture present evidence that the treatment destroyed the actively invasive appearance of the tumor.<sup>8</sup>

## SUMMARY

The sterile filtrate of *B. histolyticus* growing on the Brown-Pearce rabbit epithelioma was injected under a variety of experimental conditions into rabbits having the same type of tumor from which the filtrate was

TABLE 5—Experiment 5\*

	Rabbit Supplying Tumor	Number of Prophylactic Injections	Total Number of Injections	Rabbit Receiving Tumor	Number of Prophylactic Injections to This Rabbit	Total Number of Injections	Longevity After Tumor Inoculation Days		Comment
Experimental group I	207	19	40	214	13	56	47	Living	tumor growing
	207	19	40	215	13	56	47	Living	(?) immune no take

Control	207	19	40	217			43	Living	tumor growing
	207	19	45	218			43	Living	tumor growing

\* The P and F<sub>1</sub> generations of the hosts having tumor received prophylactic injections prior to inoculation with tumor. Injections of filtrate were also continued afterward until tumor tissue was removed for transfer to F<sub>1</sub> and F. Three rabbits of the latter group (number 214, 215 and 216) were likewise given prophylactic injections of the filtrate. Injections following inoculation with tumor were continued to date.

Tumor from the second rabbit (207) was then inoculated into the five rabbits listed in table 5, which summarizes this experiment. If one discounts the case of rabbit 215, in which the tumor failed to take, it will be noted that the two rabbits which received the injections are apparently in the same clinical condition as are the two untreated controls. The tumor has thus passed through three generations of treated hosts and at the present time appears to be capable of unchecked growth, since all the rabbits in which the tumor took have growing primary and metastatic tumors, even while the daily injections are being continued.

Further evidence to indicate that injection of the filtrate does not alter significantly (1) the number of takes, (2) the percentage of tumors the growth of which has become static or regressive (3) the progressive growth of the tumors and (4) the number of animals dying of tumor metastases is illustrated in table 6. This table presents a general summary, without regard to the particular type of treatment in the various experiments. Rabbits 78 and 81 might perhaps be more properly listed under the nontreated column, as they received only a small number of injections before they died of tumor metastases. Since the number of controls practically equaled the number of injected animals, the striking parallelism in the clinical course of the various groups seems significant.

**Examination of Tissue**—No difference could be observed in the growth habits of the tumor in the treated and the nontreated animals. The usual mode of dissemination of the tumor inoculated in the testis

prepared. Injections of this filtrate were found to have no apparent effect on the rate of growth of the tumor or on the microscopic appearance of the tissue. Even when the tumor was propagated through two genera-

tions of hosts both of which had received injections of the bacterial filtrate before and after inoculation with the tumor, its highly malignant potentialities were not checked.

<sup>8</sup> The author is indebted to Dr. William B. Hawkins, associate professor of pathology, University of Rochester School of Medicine and Dentistry, for reviewing with him all the microscopic slides prepared in connection with this study.

## RESULTS OBTAINED BY THE USE OF FEVER THERAPY

IN THREE TYPES OF CASES USUALLY REFRAC-  
TORY TO OTHER TYPES OF TREATMENT

M. HILL METZ, M.D.

DALLAS, TEXAS

The principles underlying the use of fever therapy in the treatment of certain infectious and allergic conditions are only partially understood. It is not my purpose in this report to enter into a theoretical discussion of these principles. I wish to report the striking results obtained by the use of fever therapy in cases of gonorrheal ophthalmia, Sydenham's chorea, and a severe case of status asthmaticus.

### GONORRHEAL OPHTHALMIA

This case is reported because of the excellent and immediate results following treatment with fever therapy.

J. D., a Negro boy, aged 6 years, was admitted to the Eye Service of the Cincinnati General Hospital Feb. 20, 1935, chiefly because of a sore left eye of six days' duration. There was at first swelling and redness of the lids followed shortly by a profuse yellowish white discharge. There was no previous history of eye disease or genito-urinary infection. The temperature was 100 F., pulse 110, respiration rate 20. The patient was normally developed and well nourished. The right eye was completely normal. The left eye showed markedly swollen lids, much photophobia and lachrimation. There was severe conjunctivitis with ciliary injection and profuse purulent discharge. Two ulcers were present in the cornea, one was large and centrally placed with an irregular outline, and the other was circular, and the bases of both were covered with a gray purulent exudate. The left preauricular gland was palpable. A gram stain of the pus from the left eye showed many pus cells with only gram-negative intracellular diplococci in great numbers.

February 21 the patient was given fever therapy by means of the Kettering Hypertherm. A temperature was maintained between 106 and 107 F. for seven hours. After this there was less injection and the ulcers appeared as scar with no exudate. There was little discharge, and careful search of stain specimens showed a few pus cells and no organisms. Although the eye continued steadily to improve and no gonococci were demonstrated, two more fever treatments of six hours each between 106 and 107, were given. February 26 there was no photophobia, conjunctival injection or discharge. The small corneal ulcer was completely healed and there was only a superficial scar and a nebulous opacity at the site of the larger one.

The patient was discharged, March 13, with only a small nebular opacity at the site of the corneal ulcer. Examination later revealed further contraction of the scar.

This result was duplicated in another equally severe case of gonorrheal ophthalmia in May 1935.

### SYDENHAM'S CHOREA

Six patients with Sydenham's chorea were treated with fever therapy by means of the Kettering Hypertherm. All were girls and their ages ranged from 8 to 15 years. There was no other outstanding manifestation of the rheumatic state, either active or inactive, except for the chorea. These cases were of the most severe type, the patients having been sick for from two weeks to ten months. They had been kept at complete bed rest and had been treated with all the ordinary

measures and with much sedation. Still the condition remained of the most violent type, requiring continuous restraints to prevent self injury. Because of the difficulty in feeding, of vomiting and of excessive movements, all were very poorly nourished. All were given from three to five treatments at weekly intervals, each treatment consisting of from three to four hours, with temperature between 106 and 107 F. Shortly after the first treatment in each case there were fewer choreiform movements, and the patients rested with fewer sedatives. Improvement was slow but definite, and in from two to four weeks after the last treatment all involuntary movements had disappeared and the patients ate and slept normally. In only two cases was there the suggestion of choreiform movements under the stress of excitement. These cases have been followed for from two to eight months, and there has been no recurrence of symptoms in any. The following case is typical.

M. R., a white girl, aged 15 years, admitted to the Cincinnati General Hospital, April 7, 1935, had been noted to have queer facial grimaces two weeks previously. These had increased in severity, followed by excessive choreiform movements of the arms and legs and finally the inability to remain in bed without restraint. The patient could not speak and there was incontinence of urine and feces. The past history was irrelevant except for several acute infections of the upper respiratory tract during the winter months.

The patient was fairly well nourished. There were excessive involuntary movements of the entire body. The temperature was 100 F., the pulse 110, and the respiration rate 20. The blood pressure was 110 systolic, 80 diastolic. The only abnormal physical manifestations were an injected pharynx and dental caries. All deep tendon reflexes were hypoactive. The abdominal reflexes were absent and there were no positive reflexes of the pyramidal tract. The Wassermann reaction was negative. Examination of the blood revealed hemoglobin 80 per cent, red blood cells 5,000,000 and white blood cells 8,000 with a normal differential count. Urinalysis gave normal results.

April 11 the patient was given her first fever treatment, after which she was somewhat quiet. The chorea remained about the same until after the second treatment, a week later, at which time there was noticeable definite improvement. She continued to improve, the temperature became normal, and she was able to speak. She was given two more treatments the last one on May 20. There has been no evidence of chorea since the last treatment, and after two months she is still well.

### BRONCHIAL ASTHMA

Eight cases of severe intractable bronchial asthma were treated with fever therapy by means of the Kettering Hypertherm, at the Cincinnati General Hospital. All were of the most severe type, having presented this disease for from two to twenty years. Multiple sensitivities to bacteria, foods and pollens were present in each case. All patients had had severe attacks of status asthmaticus at repeated intervals, oxygen therapy having to be administered. Three of the patients had required considerable morphine, and frequent daily injections of epinephrine were necessary in all cases. The relief offered has been complete in three cases, lasting from two to six months. In four cases followed for from one to twelve months there has been only occasional mild recurrence, and in one case there was little or no improvement. No patient received more than four treatments at weekly intervals, each one consisting of from three to five hours of fever between 106 and 107 F.

This type of therapy is not recommended as effecting consistent cure or even as a means of alleviating all bronchial asthma, but it is worth trying in severe asthmatic cases that respond to no other form of therapy. The following case report is an example of the type of case treated.

C B, a white woman, aged 29, had symptoms of bronchial asthma in 1922, at which time she was 16 years of age. Her attacks increased in severity and duration and she was admitted to the Cincinnati General Hospital for the first time in 1929. At that time a complete physical examination was negative except for undernourishment and the typical manifestations of bronchial asthma. The sputum was mucoid and showed many eosinophils. Roentgen examination of the chest was entirely negative. Autogenous vaccine therapy was started with organisms from the upper respiratory tract.

Skin reactions were positive to inhalants, foods and bacteria. The patient had received more or less continuous vaccine therapy for the past four years, as well as the other ordinary measures for the treatment of bronchial asthma.

Since 1929 she had been admitted to the hospital repeatedly, many times being in such severe respiratory distress as to require continuous oxygen therapy for several days. Repeated roentgenograms revealed an increasing degree of emphysema. Jan 30, 1935, she had her first fever treatment lasting for three hours, between 106 and 107 F. After the first two hours she could breathe freely. Although there were no evidences of asthma and she was symptom free, she was given two more treatments at weekly intervals. She has been followed closely up to July 1, 1935, and she has remained free from bronchial asthma and has gained 15 pounds (68 Kg).

## Clinical Notes, Suggestions and New Instruments

### FATAL IODODERMA FOLLOWING INJECTION OF IODIZED OIL FOR PULMONARY DIAGNOSIS

D W GOLDSTEIN M D FORT SMITH ARK

Cases of iododerma and iodism<sup>1</sup> from iodized oil have previously been reported. In a review of the literature however, no fatal case of iododerma has been encountered following the injection of iodized oil into the lung.

A very interesting case of fatal iododerma was recently reported by Eller and Fox.<sup>2</sup> These authors also reviewed the literature on the subject. Their case presented a polymorphous type of eruption. The individual lesions varied from small fleshy papules and crusted nodules to large fungating granulomatous tumors.

The dangers of the injection of iodized oil have been well expressed by the Council on Pharmacy and Chemistry of the American Medical Association.<sup>3</sup> The fact is emphasized that this is distinctly a surgical procedure involving more or less risk, and that before such a diagnostic measure is instituted the advantages and disadvantages of such a procedure should be carefully considered.

#### REPORT OF CASE

**History**—R C a man aged 47 was referred to me by Dr J D Riley, superintendent of the Arkansas State Sanatorium, with the following history. He had been admitted to the sanatorium May 17, 1934, complaining of weakness and loss of weight. The physical examination revealed scattered rales at both bases. The rest of the physical examination was essentially negative.

From the Cooper Clinic

<sup>1</sup> Firth J O. Iodism. J A M A 100 110 (Jan 14) 1933.  
Carmichael D A. Iodine Poisoning and Iodism from Lipiodol. Canad M A J 26 319 320 (March) 1932.

<sup>2</sup> Eller J J and Fox E C. Fatal Iododerma. Arch Dermat & Syph 24 745 (Nov.) 1931.

<sup>3</sup> Dangers of the Injection of Iodized Oil. J A M A 99 1946 (Dec 3) 1932.

Two days before entering Sparks Memorial Hospital of Fort Smith, Ark. 20 cc of iodized oil<sup>4</sup> was injected into the lung for diagnosis. No unusual symptoms were noted following the injection. Immediate films showed no bronchiectasis. The following morning the fever was 101.4 F. At this time a papulopustular eruption was noted over the forehead and face which gradually spread to the upper part of the chest.

Distribution of lesions and bullae

and the extensor surface of the arms and hands. The patient became nauseated and finally entered the hospital in a stupor, the result, no doubt, of a severe toxemia.

**Examination**—The physical examination was essentially negative with the exception of the skin.

The patient presented an eruption that was more or less limited to the face and upper extremities, shown in the accompanying illustration. Over the extensor surfaces of the arms and the back of the hands were pea to hickory nut size discrete, thick walled bullae and pustules, some of which were definitely hemorrhagic. The face was markedly edematous and the eruption here was more diffuse in character. Most of the bullae and pustules had ruptured, forming large crusted moist areas. In addition many verrucous and fungating lesions were noted. The scalp was also involved, but to a lesser extent. The tongue was moderately swollen and presented some hemorrhagic areas. The rest of the oral mucosae showed lesions of the vesicobullous type. Because of the marked lingual edema and lesions in the mouth, examination of the pharynx, larynx and adjacent structures was impossible.

The urine was tested for the presence of iodine. This was repeatedly positive, the specific gravity was 1.012, other observations were albumin 2 plus, granular casts 2 plus, a few blood cells and hyaline casts.

Examination of the blood showed hemoglobin 84 per cent, red blood cells 4,240,000 and leukocytes 21,000, with a differential count of polymorphonuclears 81 per cent, mononuclears 5 per cent and lymphocytes 14 per cent. The Kolmer Wassermann and Kahn tests were both negative.

Serum from the bullae was negative for iodine. Culture, however, showed a scattered growth of staphylococci.

The diagnosis was iododerma and acute glomerulonephritis.

**Treatment**—Treatment consisted of the injection of physiologic solution of sodium chloride and dextrose intravenously. In spite of great caution there was rather marked irritation of the kidneys, due in part no doubt, to excretion of the iodides. Because of this further saline injections were discontinued. The rest of the general treatment was symptomatic in nature. Local treatment consisted of soothing applications of lotions and wet dressings.

**Clinical Course**—In spite of therapy new lesions developed and the toxemia increased. The lesions, which were at first

<sup>4</sup> Lipiodol Lafay was used.

present over the arms and face, gradually spread over most of the body. Three days prior to death, large bullae developed but soon ruptured, leaving moist, raw surfaces. The nephritis became more marked and the patient died twenty-six days after the onset of the present illness. Unfortunately postmortem examination was refused.

#### SUMMARY AND CONCLUSIONS

In a case of fatal iododerma following the injection of iodized oil into the lung for diagnosis there was no question concerning the diagnosis as evidenced by the history of injection of the drug into the bronchi, typical cutaneous lesions and demonstration of iodine in the urine. Although absorption from the bronchial mucosae is negligible it is entirely conceivable that in a markedly sensitive or allergic individual a sufficient quantity could have been absorbed to be responsible for the eruption. Death no doubt, ensued as a result of a nephritis plus an overwhelming toxemia.

#### A MODIFIED STAIN FOR STIPPLE CELLS IN LEAD POISONING

RUTH A. MCKINNEY, PH.D. AND SAUL KOSENZWEIG, M.D.  
DETROIT

The increasing recognition of lead poisoning as an industrial hazard has stimulated the search for a rapid reliable stain for the stipple cells found after lead absorption. Further experimentation with the Henderson stain<sup>1</sup> has demonstrated that Wright's blood stain may be substituted for the staining mixture recommended by Henderson. With this change it is possible not only to note and to count the stipple cells but also to make the usual differential count of the white blood cells at a single examination.

The three reagents required are kept for convenience in covered Coplin jars. The technic is as follows:

Fix dried smear in acetone-free methyl alcohol for from three to five minutes and transfer directly to Wright's stain (staining time predetermined for each lot of stain used), wash in tap water and transfer to dilute ammonia water (25 cc of stronger ammonia water in 1,000 cc of distilled water), dip up and down rapidly until blue color runs from slide, wash in tap water, dry and examine.

The finely stippled or coarsely dispersed 'basophilic aggregations' in the red blood cells appear distinctly black against the gray or pink of the stained cell. The white blood cells retain the usual nuclear stain.

The ratio of lead-affected cells to the normal red cells is determined by an adaptation of the Fomo platelet counting technic.<sup>2</sup> A minute opening in a paper disk dropped into the ocular diaphragm gives a suitable counting field. The stipple cells and the normal red cells in each field are counted but tabulated in separate columns, until 250 normal red cells have been counted. The number of stipple cells is then multiplied by 4 giving the ratio of such cells to 1,000 normal cells. The number of thousands of red blood cells per cubic millimeter multiplied by the number of stipple cells per thousand cells gives the approximate number of lead stipple cells per cubic millimeter of blood.

This staining method offers nothing fundamentally new, its chief advantage lies in the fact that a simplification and combination of two previous technics makes possible:

1 A rapid detection and enumeration of stipple cells in a spread which is also adequately stained for a differential count of the white blood cells.

2 The utilization of reagents usually found in any physician's office or clinical laboratory.

3 A technic which stains dried smears two months old as satisfactorily as fresh dried smears.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT  
HOWARD A. CARTER Secretary

### HOGAN BREVATHERM SHORT WAVE DIATHERMY UNIT, MODEL 8800 (TWO-TUBE) ACCEPTABLE

Manufacturer McIntosh Electrical Corporation, Chicago

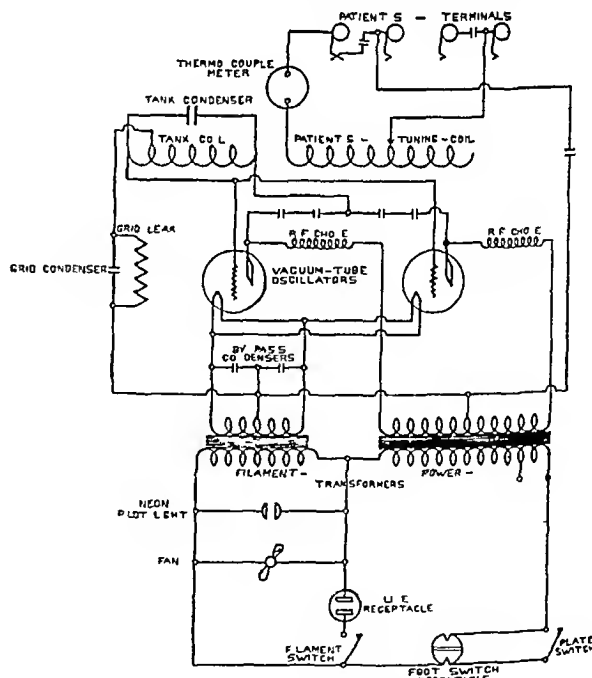

This unit is designed to produce electric current oscillations of high frequency which are suitable for the production of heat within the body tissues and for surgical tissue cutting.

The circuit is of a well known, alternating current operated push-pull oscillator type. The pick-up coil of the patient's circuit is inductively coupled to the oscillator or tank coil. The wavelength is approximately 233 meters. Under maximum load the power input is less than 1,000 watts. Since there is no acceptable method for measuring the output of short wave machines, this value is not given. The temperature rises of the transformers after operating the machine at full load for two hours came within the limit of safety prescribed by the Council. Both cuff and pad electrodes are furnished as standard equipment. The shipping weight of the unit is about 175 pounds.

At the request of the Council the machine was investigated and the data were submitted for consideration. The tissue heating effect in the human thigh was observed. Cuff electrodes were applied to the thigh, one posterior to the hip, the other anterior to the knee. Thermocouples were introduced into the deep lying tissues and also into the subcutaneous tissues. They were placed at a point midway

Hogan Brevatherm Short Wave Diathermy Unit Model 8800

Schematic diagram of circuit

between the hip and the knee, or midway between the cuff electrodes, and removed during the time of treatment. After twenty minutes treatment, the machine being operated at the patient's tolerance the temperature rise and final temperature (average of five tests) were observed to be comparable to those temperatures obtained by conventional diathermy which was

used as a control. The conventional diathermy currents were applied to the thigh by triplate electrodes, one on the medial and one on the lateral aspect.

The cuff electrodes used in the investigation were made of metal surrounded by thick protecting felt and enclosed in a sateen bag. Several layers of toweling, a felt pad or both materials, were placed next to the skin to absorb perspiration.

Burns may be produced by this machine, but they may be avoided by ordinary precaution their likelihood to occur is much less than with conventional diathermy.

This unit was tested in a clinic acceptable to the Council, there the reports of the investigation were confirmed and the machine was considered as giving satisfactory service for the purposes for which it is intended.

In view of the favorable report on the machine, based on its performance when cuff electrodes were used, the Council on Physical Therapy voted to include the Hogan Brevatherm Short Wave Diathermy Unit, Model 8800, in its list of accepted apparatus.

## Council on Pharmacy and Chemistry

### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

**SOLUTION LIVER EXTRACT-VALENTINE**—A solution of a water-soluble fraction extracted from edible livers of mammalian animals.

**Actions and Uses**—Solution liver extract-Valentine is used in the treatment of pernicious anemia and sprue.

**Dosage**—Solution liver extract-Valentine is administered orally. Ninety cubic centimeters, or 3 ounces, is the average daily dose, this is usually divided into three parts and administered at the end of each meal. The daily amount may be reduced to 60 cc, or 2 ounces, when the erythrocyte count reaches 4.5 million per cubic millimeter. If the count tends to increase above this level the quantity may be reduced to 30 cc or 1 ounce, daily. The maintenance dose should be varied in keeping with the requirements of the individual patient.

Manufactured by the Valentine Company, Inc., Richmond, Va. No U. S. patent. U. S. trademark 298,963.

To prepare solution liver extract-Valentine livers from edible animals are ground directly into water. The mixture is heated to approximately 90°C to coagulate protein and to inactivate liver enzymes. The coagulated protein is then removed by filtration. Approximately 9 per cent of glycerin and 0.2 per cent of sodium chloride are added to the finished product.

**AMYTAL** (See New and Nonofficial Remedies, 1935, p. 94)

The following dosage form has been accepted:

Tablets Amytal ¼ Grain

**ORTAL SODIUM** (See New and Nonofficial Remedies, 1935, p. 100)

The following dosage form has been accepted:

**Kapsels Ortol Sodium with Phenacetin**. Each kapsel (hermetically sealed capsule) contains oritol sodium 1½ grains (0.1 Gm.) and aceto phenetidin (phenacetin) 3 grains (0.2 Gm.).

**CALCIUM GLUCONATE** (See New and Nonofficial Remedies, 1935, p. 139)

The following dosage form has been accepted:

**Ample Compound Solution of Calcium Gluconate 10%**. 10 cc U. S. S. P. Co.—A solution containing in each 10 cc calcium gluconate 1 Gm. (15½ grains), dextrose anhydrous 0.5 Gm. (7½ grains), citric acid 0.037 Gm. (½ grain), and lactic acid 0.1 Gm. (1½ grains).

Prepared by the United States Standard Products Company, Woodworth, Wis. U. S. patent applied for.

**BISMUTH SUBSALICYLATE** (See New and Nonofficial Remedies, 1935, p. 123)

The following dosage form has been accepted:

**Bismuth Salicylate in Oil U. S. S. P. Co.** A suspension of bismuth subsalicylate U. S. P. 2 grains (0.13 Gm.) and chlorbutanol 1 per cent in neutral olive oil to make 1 cc. Marketed in bottles containing 1 ounce.

Prepared by the United States Standard Products Company, Woodworth, Wis.

## Committee on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

## UNSOLVED PROBLEMS IN AMEBIASIS

Despite the remarkable advance in knowledge of amebas and the infections which they cause, many important problems remain for further study. Craig,<sup>1</sup> long a distinguished student of parasitologic problems, has recently reviewed three such problems. The first concerns the question of the existence of an avirulent strain of *Endamoeba histolytica*. The absence of definite symptomatology in many persons harboring this parasite has led, he states, to the belief that there must exist strains that are nonpathogenic and that such strains may live in the human intestine for indefinite periods. Brumpt and Sinic have made observations tending to show that there is another ameba which is nonpathogenic but identical in morphology and life history with *Endamoeba histolytica*. Many other observers, however, have failed to confirm these results. Craig himself states that he has repeatedly produced dysenteric symptoms and ulcerative lesions in kittens with strains of *Endamoeba histolytica* from symptomless carriers. In one instance a cultural strain obtained from a presumably healthy carrier and cultivated for more than four years was pathogenic to kittens at the end of that period. He emphasizes the point, therefore, that the absence of symptoms in amebic infection does not mean that the strain that is present is not virulent as far as the production of lesions is concerned. The question of the existence of a harmless species must, he believes, be considered as still remaining unsolved, but it is of great importance.

The problem of variation in virulence of strains of *Endamoeba histolytica* is closely related. Whether the differences in virulence that exist are fixed characteristics of each strain or whether the virulence of a strain may be increased or decreased by cultivation and passage through experimental animals or man needs to be determined. As long ago as 1914 an increase in virulence in a strain of *Endamoeba histolytica* from a relapsing case of amebic dysentery after passage

through kittens was reported. Since that time a number of investigators, especially Meloney and Fryc, have appeared to corroborate the fact of variation in virulence of different strains. Frequently it has been noted that the virulence of some strains may be raised by passage through animals. A number of other investigators, however, fail to confirm this view. Craig concludes that there probably exist certain strains of *Endamoeba histolytica* which are naturally more virulent than other strains. Up to now, however, no strain of this organism has been demonstrated to be nonpathogenic or capable of living in the lumen of the bowel of man for indefinite periods without producing lesions. He feels also that the virulence of certain strains can be raised by continuous passage through kittens and dogs but that final proof that such an increase in virulence occurs during passage through man is not yet available.

Finally, the question of immunity to *Endamoeba histolytica* has received relatively little study. The only evidence of natural immunity is afforded by the epidemiology of the infection, but the data available are so scattered and so confusing that it is impossible to arrive at a conclusion regarding the true existence of natural immunity. In all regions where the incidence of amebic infection is high, a considerable proportion of the inhabitants escape infection although exposed apparently as much as those infected. This suggests but does not prove the existence of natural immunity. The spontaneous recovery of some persons from infection also points in this direction. Evidence of acquired immunity may be suggested from study of the so-called immune bodies produced in the blood stream by inoculation with cultures of *Endamoeba histolytica* or with antigens made from such cultures. Evidently specific complement fixing bodies occur in the blood of animals and human beings infected with *Endamoeba histolytica* and can be produced in animals by the injection of antigens prepared by the extraction of cultures of this parasite. The fact that such bodies exist and can be produced experimentally and that complement fixation occurs not only in persons suffering from amebic dysentery but also in carriers without symptoms and that in fact the reaction is stronger in such carriers than in those having active symptoms demonstrates that there exists a reaction between the tissues of the body and the parasite, resulting in the production of these substances. The relation of complement fixing bodies to immunity is at present unknown. Craig thinks it reasonable to conclude that these bodies indicate a reaction which in all probability leads to more or less immunity in infected animals or human beings, but as far as scientific data are concerned there is no support of this belief except that furnished by the epidemiology of the infection.

These are only a few of the numerous problems in amebiasis remaining to be solved. As has been repeatedly pointed out in these columns and elsewhere, the

<sup>1</sup> Craig, C. F. Some Unsolved Problems in the Parasitology of Amebiasis. *J. Parasitol.* 22: 1 (Feb.) 1936.

knowledge that amebic infections are widespread in temperate as well as in tropical and semitropical lands indicates the need for active investigation along these lines

#### EIGHTIETH BIRTHDAY OF SIGMUND FREUD

On May 6 the world celebrated the eightieth birthday of Sigmund Freud. The difficulty of evaluating the influence of a contemporary is doubled in the case of Sigmund Freud, the inevitable phases of reaction and consternation always provoked by new discoveries have not yet been passed. The influence of the freudian concepts has been universal and not restricted to the theory and therapy of mental diseases. The concept of the unconscious has deeply modified the subjective attitude of human beings toward life and necessitated a thorough reorientation of our philosophic outlook. Human beings seem instinctively to resent the acknowledgment forced on them by Freud that even their own personalities are removed from the sovereign influence of their conscious selves and that they are not even complete masters of their own actions. The discovery of the unconscious has led to a striving to bring the unconscious under the domination of consciousness, this is the essence of the technic of psychoanalysis.

In spite of the tremendous influence of Freud on contemporary thought, it is still difficult to appreciate fully the nature and extent of his influence on his own field, modern psychiatry, and on medicine in general. Modern psychiatry is in a phase of fermentation and turbulent change. Its development has been characterized by two features: (1) the effort to give an accurate description of the clinical pictures of mental disturbances and classify them according to descriptive nosologic units, and (2) the attempt to follow in the study and therapy of psychiatric disturbances the principles prevailing in the rest of medicine. Perhaps these tendencies have interfered with the development of psychiatry as a science. Psychiatry, in its concern to live up to the scientific standards of the rest of medicine, developed a distaste toward psychologic phenomena. These psychologic phenomena seemed reminiscent of obscure medieval ideas about evil spirits, exorcism and general metaphysical concepts. The emphasis on precise description became exaggerated into unwillingness to explain, and explanation and understanding were confused with speculation. Freud's great accomplishment consisted in introducing standardized psychologic methods for the investigation of psychologic phenomena and in observing psychopathologic processes in the continuity of psychologic causality. This attempt was often considered contradictory to the attempt to understand psychic phenomena in terms of biology. Freud, however, emphasized biologic orientation. His scientific credo is that though psychic life must be understood in terms of psychology, this knowledge must be gradually integrated with the somatic knowledge of the central nervous system and the process of life in general.

Psychoanalysis is offered at the same time as a method of therapy. Freud developed most of his theoretical ideas from observations made during his attempts to cure patients suffering from mental ailments. Psychoanalysis is set forth as etiologic therapy based on a knowledge of the nature of the pathologic condition instead of therapy based on empiricism. Only this etiologic orientation can explain the manner in which a therapist who began with the modest aim of helping hysterical patients discovered the unconscious mind as an entirely new territory of research.

Psychoanalysis provides an approach to a large group of sufferers who previously were almost neglected by medicine—the psychoneurotic. In this field temporary improvement obtained by the purposeful or unintentional use of suggestion has often been misjudged as a real therapeutic result. It is too early to pass final judgment on the therapeutic efficiency of psychoanalysis. Like all medical methods of therapy, it has definite limitations. In this field as in others, the constitution of the patient is the unchangeable factor.

Sigmund Freud was born of Jewish parentage on May 6, 1856, at Freiburg in what is now Czechoslovakia. When 18 years old he entered the medical school in Vienna and from the beginning his interest was in the direction of psychiatry. The teachers who had the deepest influence on Freud's development in the university in Vienna were the great classic physiologist Ernst Brücke and the psychiatrist Meynert. The early phases of Freud's work in medicine were spent in the laboratory. He became an expert in brain anatomy and made valuable contributions to the pathology of infantile paralysis. In 1885 he was appointed lecturer in neuropathology on the basis of his histologic and neurologic publications. On Brücke's recommendation he received a traveling fellowship which he used to go to Paris as a student of Charcot in the Salpêtrière. This trip may be considered one of those fortuitous events which so often become decisive for the further fate of individuals. No other man had a greater influence on Freud's later development than Charcot, unquestionably the greatest authority in neurology of those days. Charcot was an empiricist and a clinician in the best sense. His great reverence for facts enabled him to emancipate himself from the current theories and dogmas in medicine and to recognize the psychologic element in hysterical phenomena. By the help of the technic of hypnosis Charcot in Paris and Bernheim and Liebeault in Nancy had been able to demonstrate experimentally the effect of unconscious psychic forces on behavior and neurotic symptom formation. A second decisive coincidence in Freud's life was his meeting with Joseph Breuer. Freud's enthusiasm for his new field was intensified by Breuer's reports of his patient Anna, a hysterical young woman whom Breuer tried to cure through hypnosis. In a sense this patient may be considered as the inventor of the therapeutic

principle of psychoanalysis To the free flow of her speech during hypnosis, by which she gave expression to forgotten and repressed traumatic experiences, she gave the name "talking cure" Though Freud eventually discarded the use of "cathartic hypnosis," even in the most modern technic of psychoanalysis the principle of this "talking cure" is still present in the form of free association

From this time Freud's life began to center more and more around his efforts to understand and cure first mental disturbances and then the personality as a whole For a long time he worked entirely alone and even severed his collaboration with Breuer, whose vision was more limited and who shrank back from those unusual phenomena which the deeper penetration into the unconscious soon revealed It was not until 1902 that a number of young medical men began to gather around Freud With few exceptions all have devoted their lives to the development of psychoanalysis

Among the first to join Freud in his study of unconscious processes were the representatives of the Zurich school of psychiatry, most prominent of whom have been Bleuler, Jung, Eitingon and Abraham Whereas Jung later became one of the dissenters and Bleuler's attitude has been checkered by repeated alternations between enthusiasm and antagonism, Eitingon and Abraham adhered consistently to the fundamental facts and principles of psychoanalysis and had a great share in its development and organization

In 1910 an international psychoanalytic organization was formed, which, except for the period of the World War, has held an international congress every second year At present almost every country of the world has psychoanalytic societies, the members of which are almost entirely, and in America exclusively, physicians The first psychoanalytic institute in which training in psychoanalysis was conducted in a systematic way was founded by Eitingon in Berlin in 1919 Now a number of such institutes exist in different cities of Europe and America The first psychoanalytic society in America was founded in New York under the leadership of Brill The Chicago Psychoanalytic Institute, now partially supported by the Rockefeller Foundation, has been chiefly devoted, under Dr Franz Alexander, to the study of psychophysiologic interrelationships as the most important means of integrating the freudian concepts with the medical and biologic sciences

Today psychoanalysis and its followers are still somewhat isolated from the rest of medicine No doubt the first bitter emotional reactions against the startling concepts of Freud are responsible for this isolation Seen from historical perspective, however, the thirty year period of isolated development of psychoanalysis is not remarkable The fight for the scientific study of the human body by dissection lasted for centuries, the unbiased objective study of the human personality must prevail over greater emotional obstacles

Late in his career Freud is receiving official recognition in many places His first recognition came from contemporary leaders of thought and literature, such as Thomas Mann in Germany and Romain Rolland in France The city of Vienna made him an honorary citizen, and in 1930 he received the Goethe prize in Germany He was elected an honorary member of the Royal Medical Society of England in 1935

Freud's influence on medicine is no doubt still in its infancy While the increasing interest in psychologic factors of somatic disorders should not be attributed wholly to Freud, no other man has contributed a greater stimulus toward study and understanding of psychologic phenomena

His contributions to medicine and those on the application of psychoanalysis to the cultural fields are collected in twelve volumes, which have been published by the International Psychoanalytic Press The position of Freud as a great leader is secure Great epochs in medicine are defined by great leaders As we associate Vesalius with anatomy, Harvey with physiology, Virchow with pathology and Pasteur with bacteriology, we shall come to consider Sigmund Freud as the founder of a new trend of thought in psychiatry—an investigator with a "profound insight into the workings of primitive mentality"

#### VITAMIN D MILK

The reports several years ago that vitamin D fed to infants or to chicks as irradiated ergosterol was not as effective as an equal number of rat units of cod liver oil have stimulated a number of investigations on the comparative merits of various antirachitic preparations Because of the practicability of administering vitamin D to infants directly in milk, this fluid fortified with the vitamin, either by the addition of concentrates, by the feeding of irradiated yeast to the cow, or by the direct irradiation of the milk, has received special attention Clinical experience with the different types of "vitamin D milk" has indicated that, in general, all these forms are effective to the extent of their unitage for both the prevention and the cure of rickets in infants Unit for unit there appears to be no great difference between the antirachitic value of the three types This opinion is borne out in one of the more recent studies on rachitic children<sup>1</sup> As judged by roentgenograms and the concentrations of calcium and of phosphorus in the blood serum, the authors concluded that there were no practical differences between the antirachitic value of milk from cows fed irradiated yeast, sometimes called "yeast milk," and that of irradiated cow's milk If a slight difference actually existed, it was thought to be in favor of the milk irradiated directly

<sup>1</sup> Gerstenberger H J Horeish A J Van Horn A L Kraus W E and Bethke R M Antirachitic Cows Milk A Comparative Study of Antirachitic Value of Irradiated Cows Milk and of Milk Produced by Cows Fed Irradiated Yeast J A M A 104 816 (March 9) 1935

A recent experimental investigation on chicks<sup>2</sup> however, seems to indicate that in this species a distinct difference exists between the antirachitic activities of "yeast milk" and of "irradiated milk." Day-old chicks were fed a rachitogenic basal diet either alone or supplemented by the various vitamin D preparations under investigation. These substances had previously been assayed on rats and therefore could be administered in comparable amounts on a rat unit basis. As an index to the antirachitic potency of the test substances, the ash content of the tibia was determined at the end of five weeks. The results demonstrated that "irradiated milk" is approximately ten times more effective than the same number of rat units of "yeast milk" and, further, that the antirachitic activity of the former compares favorably with that of cod liver oil and irradiated cholesterol. It is of some interest that the latter result confirms that of another investigator<sup>3</sup> regarding the relatively high efficiency of irradiated cholesterol as a source of vitamin D for the chick.

A distinct difference between the vitamin D content of the cream and that of the skim milk portion of "irradiated milk" and "yeast milk" was also described.<sup>2</sup> Nearly all the vitamin D potency in both cases was found in the cream, the skim milk fraction being almost inactive. Furthermore, as was found with the whole milk, the cream from the irradiated milk possessed a much greater vitamin D potency than that from yeast milk.

The foregoing investigation gives no support to the possibility that the baby chick can be used with greater accuracy than the rat for ascertaining the antirachitic effectiveness of different vitamin D containing substances in infants. However, it is of some interest in this connection that according to a recent clinical study<sup>4</sup> the feeding of "yeast milk" to premature infants as the sole source of vitamin D proved to be inadequate for achieving complete protection against rickets.

Unfortunately, the antirachitic efficacy also of irradiated and other types of fortified milk was not studied since it seems possible that under the physiologic strain imposed by prematurity both these infants might have shown an exaggerated differential response to antirachitic agents perhaps similar to that found in the chick.

From the foregoing citations and from the results obtained in other pertinent investigations it would seem that the question of the relative merits of various antirachitic agents is far from solved and that there is an urgent need for further carefully conducted and controlled studies of the problem, particularly in full-term and premature infants.

## Current Comment

### DESATURATION OF FATTY ACIDS

In 1908 Leathes proposed his now well known theory of desaturation of fatty acids by the liver. According to this view the liver not only selects preferentially the unsaturated fatty acids being absorbed from the intestine but also desaturates the fatty acids stored in the body depots prior to their oxidation. There is little doubt that the liver is a significant factor in the metabolism of fat but the recent experimental evidence has not all favored the view of its importance in desaturating fatty acids. Thus the modern conception of the nutritional indispensability of linoleic and linolenic acids—fatty acids with two and three double bonds, respectively—implies directly that neither the liver nor any other tissue can produce these compounds from more saturated ones. However arachidonic acid with four double bonds has been found in considerable quantities in liver and other tissues despite the fact that this fatty acid is not ordinarily a constituent of the diet. This fact strongly points to synthesis in the animal body. In a recent report Schoenheimer and Rittenberg<sup>1</sup> provide evidence of a somewhat different kind for the transformation of saturated fatty acids to unsaturated ones. In two experiments mice were fed a diet containing a saturated fatty acid in which deuterium replaced some of the hydrogen. After seven or twelve days the total fatty acids of the mouse were separated into a saturated fatty acid fraction and an unsaturated fraction and the deuterium determined in each. In both experiments deuterium appeared in the unsaturated fatty acid fraction. As the amount of it was several times that appearing in the body water the conclusion is drawn that the unsaturated fatty acids were derived from the saturated fatty acids. These experimental results obtained with ultramodern technique provide further evidence that the organism possesses the ability to desaturate fatty acids.

### THE KANSAS CITY SESSION

#### Breakfast for Members of Section on Nervous and Mental Diseases

The neuropsychiatrists of Kansas City and the Missouri-Kansas Neuropsychiatric Association will give a breakfast for the members of the Section on Nervous and Mental Diseases of the American Medical Association at the Kansas City Club, on the morning of Thursday, May 14, from 7:30 until 8:45 a.m. All members of the section in attendance at the Kansas City session are invited to attend this breakfast.

#### Alumni Banquet

The University of Illinois Medical Department Alumni banquet will be held in the main dining room of the University Club in Kansas City at 6:30 p.m. Wednesday, May 13. Dr. W. E. Keith, 100 Professional Building, Kansas City, Mo., is the local chairman in charge of arrangements for the banquet.

<sup>1</sup> Schoenheimer, Rudolf and Rittenberg, D. *J. Biol. Chem.* **113**: 505 (March) 1936.

## BROADCASTS FROM THE KANSAS CITY SESSION

Special radio programs will be broadcast from Kansas City during the week of the annual session

### NATIONAL BROADCASTING COMPANY

The following programs will be delivered over a network of the National Broadcasting Company

May 11, 3 30 p m "Nutrition and the Future of Man," by Dr James S McLester, President of the American Medical Association Fifteen minutes

May 12, 3 p m "Medicine Marching Forward" The regular dramatized program Your Health (originating in Chicago), based on papers or exhibits presented at the convention Dr W W Bauer Thirty minutes

May 13, 11 a m An interview about the Scientific Exhibit with Dr Morris Fishbein Fifteen minutes

### COLUMBIA BROADCASTING SYSTEM

The following programs will be broadcast over a network of the Columbia Broadcasting System

May 11, 1 30 p m An interview with one or more distinguished foreign visitors by Dr Morris Fishbein Subject to be announced Fifteen minutes

May 15, 2 p m A news broadcast outlining the main events of the convention Dr W W Bauer Fifteen minutes

May 15, 8 45 p m "Medicine Yesterday and Today" An interview with dramatizations (originating in Chicago) based on papers or exhibits presented at the convention Dr Paul A Teschner and the Columbia Broadcasting System commentator Thirty minutes

The hour given is central standard time eastern standard time is one hour later, mountain time one hour earlier and Pacific time two hours earlier Daylight saving time in each locality is one hour later

## RADIO BROADCASTS

The American Medical Association broadcasts over WEAf, the Red network instead of the Blue as formerly, and certain additional stations of the National Broadcasting Company at 5 p m eastern daylight time (3 o'clock central standard time, 2 o'clock mountain time 1 o'clock Pacific time) each Tuesday, presenting a dramatized program with incidental music under the general theme of "Medical Emergencies and How They Are Met" The title of the program is "Your Health" The program is recognizable by a musical salutation through which the voice of the announcer offers the toast 'Ladies and gentlemen your health' The theme of the program is repeated each week in the opening announcement, which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community day and night for the promotion of the health of the people Each program will include a brief talk dealing with the central theme of the individual broadcast

**Red Network**—The stations on the Red network of the National Broadcasting Company are

WEAF	WCSH	WBEN	ASD
WEEI	KLW	WCAE	WHO
WTIC	WFBZ	WTAM	WOW
WJAR	WRC	WWJ	WDAF
WTAG	WGY	WMAQ	

**Pacific Network**—The stations on the Pacific network are

KCO	KFI	KOMO	KFSB
KIO	KGW	KHQ	KTAR

Network programs are broadcast locally or omitted at the discretion of the local station The lists indicate stations to which programs are available

The last program of the present series is as follows

May 12 Medicine Marching Forward W W Bauer MD

A new series is under consideration for the autumn and winter of 1936-1937 Announcement will be made in THE JOURNAL when arrangements are completed

## RAILROAD TICKETS TO THE KANSAS CITY SESSION OF THE AMERICAN MEDICAL ASSOCIATION, MAY 11-15

When you purchase your ticket to the Kansas City meeting of the American Medical Association, May 11 15, be sure to ask your railroad ticket agent for a certificate, which, when properly certified to and validated will entitle you to purchase a return ticket to your home over the same route traveled to Kansas City, at one third the fare paid to Kansas City No refund of fare will be made on account of failure to present a validated certificate when purchasing return ticket For additional details about transportation to Kansas City see The JOURNAL of the American Medical Association of April 11, 1936, page 1281

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY FORWARDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC)

### CALIFORNIA

**State Medical Meeting in Coronado**—The sixty fifth annual meeting of the California Medical Association will be held at the Hotel Del Coronado, Coronado, May 25 28, under the presidency of Dr Robert A Peers, Colfax Among many other speakers will be the following physicians

Jacob J Singer St Louis, Newer Methods in the Treatment of Pulmonary Tuberculosis  
Franklin G Ebaugh, Denver, Sleep Disturbances in Clinical Practice  
Leon Ascher, Berne, Switzerland, Synergic Reaction in Clinical Practice  
Campbell P Howard, Montreal, Calcinoses with Special Reference to Its Occurrence in Scleroderma  
Paul D Foster, Los Angeles and Alton B Abshier, New York, Smallpox Vaccine in the Treatment of Recurrent Herpes Simplex  
James E Potter and Earl G Longley, Bremerton, Wash, and Francis H Redewill, San Francisco, Hyperpyrexia is an Adjunct in the Treatment of Cerebrospinal and Kahn Fast Syphilis  
Harry H Wilson, Los Angeles, Management of Alcoholism  
Francis M Pottenger, Monrovia, The Tuberculous Cavity in Its Clinical and Public Health Aspects  
Philip H Pierson, San Francisco, Silicosis  
J Homer Woolsey, Woodland, Congenital Occlusion of the Intestinal Tract  
Francis M Tindley, Santa Barbara, The Surgical Approach to Hypertension  
John B de C M Saunders, San Francisco, Important Anatomical and Functional Features of the Distal Radio Ulnar Joint

Dr Howard, who is professor of medicine at McGill University Faculty of Medicine, Montreal, will conduct a clinico-pathologic conference Tuesday, Sunday, May 24, the cancer commission will conduct a conference on pathology at the Zoological Research Hospital, Balboa Park, San Diego and one on radiology at the Hotel Del Coronado Entertainment will include the past president's breakfast Tuesday morning, the state and county society officers' luncheon, the state golf tournament at the Coronado Country Club Tuesday afternoon and the dinner and reception to President Peers in the evening The women's auxiliary will hold its seventh annual session, May 24-28

### CONNECTICUT

**Practically Free from Bovine Tuberculosis**—Connecticut is the thirty-ninth state to be admitted to the modified accredited area of states practically free from bovine tuberculosis, the U S Department of Agriculture announces Tuberculosis eradication work among cattle in Connecticut was begun more than twenty-five years ago and has been in progress in cooperation with the federal government since 1918

### DISTRICT OF COLUMBIA

**Medical Bill in Congress**—H R 12424 has been reported to the House without amendment proposing to examine and register beauty culturists in the District of Columbia

**Health at Washington**—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million for the week ended April 25 indicate that the highest mortality rate (20.3) appears for Washington and the rate for the group of cities as a whole was 13 The

mortality rate for Washington for the corresponding period last year was 198 and for the group of cities, 126. The annual rate for eighty-six cities for the seventeen weeks of 1936 was 136 as against a rate of 126 for the corresponding period of last year. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

## GEORGIA

**Society News**—A symposium on obstructive lesions of the genito-urinary tract was presented before the Fulton County Medical Society, April 16, by Drs. Montague L. Boyd, Edgar G. Ballenger, Omar F. Elder, Harold P. McDonald, William L. Champion and Samuel J. Sinkov. Dr. Frank Kells Bolland, Jr., Atlanta, discussed "Postoperative Evisceration Among the Colored Race" before the society in Atlanta, April 2.

**Death Rate from Malaria Declines**—A total of 377 deaths from malaria were reported for 1935 in Georgia representing a death rate of 124 per hundred thousand of population. This compares with a rate of 11 in 1934. Dr. Thomas F. Abercrombie, Atlanta, director of the state department of public health, stated that 1935 was the first year since 1931 in which a gross decline from the previous year in the state death rate was recorded.

**University News**—A trust fund with an annual income of \$1,000 has been established by Mrs. Olivia A. Herbert to maintain the new equipment of the recently completed Milton Antony Wing of the University Hospital, University of Georgia School of Medicine, as a memorial to her husband, a son and a daughter. Mrs. Herbert donated \$18,000 for the equipment last year. Dr. Alfred P. Briggs, assistant professor of internal medicine, St. Louis University School of Medicine, addressed members of the faculty and students, March 31, on renal function.

## ILLINOIS

**District Meeting**—The spring meeting of the Iowa and Illinois Central District Medical Association was held in Rock Island, April 9. Dr. William F. Schroeder, Rock Island, read a paper on "Use of Sodium Phenobarbital as a Preanesthetic," and Dr. Thomas G. Orr, Kansas City, Mo., discussed "Important Factors in Preoperative and Postoperative Therapy, with Special Reference to Intravenous Infusions."

## CHICAGO

**Society News**—At a meeting of the Chicago Society of Allergy, April 20, Drs. Carl A. Dragstedt spoke on "Mechanism of Anaphylaxis" and Theodore L. Squier and Frederick W. Madison, Milwaukee, "Hematologic Response in Food Allergy (Eosinophilia in the Leukopenic Index)." A symposium on physical therapy as employed in ophthalmology was presented before the Chicago Ophthalmological Society, April 20, by Drs. Oscar B. Nugent, James Larkin, James T. Case and John S. Coulter. Dr. Frank J. Jirka, state health commissioner, addressed the Douglas Park Branch of the Chicago Medical Society, April 21, on activities of the state health department, while Dr. Harry J. Isaacs discussed the medical and surgical aspects of jaundice. At a meeting of the Chicago Pediatric Society, April 21, the "Evaluation of Oxygen-Carbon Dioxide Mixtures in the Treatment of Pneumonia" was discussed by David J. Cohn, Ph.D., Dr. Albert L. Tannenbaum, A. Baird Hastings, Ph.D., and Dr. William Thalhimer.

## IOWA

**Annual Renewal Fees Due Before June 1**—All licenses to practice medicine and surgery in Iowa expire annually on June 30. To renew such a license, a licensee must make a written application to the state department of health before June 1, enclosing the renewal fee of \$1. If a license expires by reason of the licensee's failure to renew it, it can be reinstated without reexamination only on the recommendations of the board of health and the payment of the overdue fees.

**Society News**—Dr. Clarence E. Van Epps, Iowa City, conducted a clinic on nervous diseases before the Washington County Medical Society in Washington, March 31. Dr. Harold Dabney, Kerr, Iowa City, discussed "X-Ray Therapy in Relation to Surgical Conditions" before the Black Hawk County Medical Society, March 17. Dr. Ewen M. MacFadden, dean of the State University of Iowa College of Medicine, Iowa City, was a guest at this meeting. Dr. Hugh H. Young, Baltimore, addressed the Linn County Medical Society in Cedar Rapids, March 8, on urology.

**Personal**—Dr. Leonard P. Ristine, superintendent of Cherokee State Hospital, Cherokee, has been appointed to a similar position at Mount Pleasant State Hospital, Mount Pleasant, succeeding Dr. M. Charles Macklin, resigned. Dr. Charles F. Obermann, head physician at the Hospital for Epileptics and School for Feebleminded, Woodward, will succeed Dr. Ristine at Cherokee. Dr. James A. Edwards, superintendent of the State Sanatorium for Tuberculosis at Oakdale, was elected president of the Iowa Tuberculosis Association, March 19. Dr. Charles F. Schilling has resigned as medical superintendent of Iowa Sanatorium and Hospital, Nevada.

## KANSAS

**Public Speakers Available**—The Shawnee County Medical Society announces that its members are now available to give medical lectures for the public. Any club or organization desiring a speaker may communicate with Dr. John L. Lattimore, chairman of the public relations committee, 618 Mills Building, Topeka. The purpose of this policy is to acquaint the public with disease, its causes, treatment and prevention. There will be no charge.

**New County Societies Organized**—The Osage County Medical Society was organized at a meeting in Lyndon, March 18. Dr. George B. Kierulff, Melvern, was chosen president, Dr. Fred G. Schenck, Burlingame, vice president and Dr. Charles W. Beasley, Lyndon, secretary. The organization of the Wabamsee County Medical Society took place in Eskridge, March 19. Officers elected are Drs. Louis M. Tomlinson, Harveyville, president, and Charles L. Youngman, Harveyville, secretary.

**Physicians Honored**—The Saline County Medical Society held a dinner meeting, March 9, in honor of Dr. Oliver D. Walker, Salina, who celebrated his fiftieth anniversary in the practice of medicine. Dr. Walker, who is 76 years of age, is a former president of the Kansas State Medical Society and the Saline County Medical Society. He is still in active practice. Dr. George M. Gray, Kansas City, was guest of honor at a banquet, recently, given by friends and associates in recognition of his eightieth birthday.

## MASSACHUSETTS

**Health Association Changes Name**—The Massachusetts Association of Boards of Health, at its recent annual meeting, changed its name to the Massachusetts Public Health Association. Dr. Paul R. Withington, Milton, was chosen president of the association at this meeting.

**Henry Jackson Lectures**—Dr. Tinsley R. Harrison, associate professor of medicine, Vanderbilt University School of Medicine, Nashville, gave the Henry Jackson Lectures of the New England Heart Association, April 30-May 1, at the Boston Medical Library. His subjects were "The Pathogenesis of Circulatory Failure" and "The Principles of Therapy in Patients with Congestive Heart Failure."

**Advisory Council Named**—Dr. William B. Keeler, health commissioner of Boston, recently appointed the following to serve as an advisory health council:

Dr. John W. Barlow, president, Boston Health League  
Dr. Alexander S. Begg, dean, Boston University Medical School  
Samuel Prentiss, dean of science, Massachusetts Institute of Technology  
Dr. Roger I. Lee, Boston  
Rev. Richard J. Quinn, diocesan director of parochial schools  
Dr. Wilson G. Smilie, professor of public health administration, Harvard School of Public Health  
Dr. George Shattuck, assistant professor of tropical medicine, Harvard University School of Medicine  
Dr. Hyman Morrison, professor of clinical medicine, Tufts College Medical School  
Mr. Horace Morrison, vice chairman, Boston Health League  
Gertrude Peabody, vice president, Community Health Association

The first advisory health council was created in 1918 by the late Commissioner Francis X. Mahoney.

## MICHIGAN

**Regional Training Center for Public Health Personnel**—The division of hygiene and public health of the University of Michigan, Ann Arbor, in cooperation with the U. S. Public Health Service, has been designated as a regional training center for public health personnel serving Michigan, Ohio, Indiana, Illinois and Nebraska in accordance with plans made possible by the National Social Security Act. It is announced that training of personnel began April 6 and will continue until July 25. The first twelve weeks of work will be offered at the university and the last four in practical field work in one or more counties of the state in which recognized county health units are in full operation. Three fields of training will be open for study: public health administration, medical officers of

health, public health engineering and sanitation, and public health nursing. State commissioners of health of each of the five states comprising the regional area have selected "trainees" for each of the courses in public health specified. Other students are admitted if they meet the entrance educational qualifications in medicine, sanitation and nursing. In addition to the regular teaching staff of the division of hygiene and public health, the following personnel has been added to conduct the work:

Carl Buck, Dr. P.H., field director, American Public Health Association  
W. Frank Walker, Dr. P.H., director, division of health studies, Commonwealth Fund  
Ira V. Hiscock, C.P.H., professor of public health, Yale University School of Medicine, New Haven  
Dr. Eugene L. Bishop, director of health, Tennessee Valley Authority  
Dr. Joseph W. Mountain, U. S. Public Health Service  
H. E. Miller, U. S. Public Health Service  
Dr. Leslie L. Jumsden, U. S. Public Health Service  
Ann M. Holmer, (public health nursing)

### MISSOURI

**Dr. Cole to Head Department of Surgery in Chicago**—Dr. Warren H. Cole, assistant professor of clinical surgery, Washington University School of Medicine, St. Louis, has been named professor and head of the department of surgery, University of Illinois College of Medicine, Chicago, to succeed the late Dr. Carl Hedblom. The appointment is effective September 1. Dr. Cole, who is 37 years of age, graduated from Washington University School of Medicine in 1920.

**Annual Spring Clinics**—The St. Joseph Clinical Society held its annual spring clinics at the Robidoux Hotel, St. Joseph, March 23-25. Dr. William W. Bauer, director, Bureau of Health and Public Instruction, American Medical Association, Chicago, addressed a public meeting Monday evening on "Popular Beliefs That Are Not So." Guest speakers at the clinics and some of their subjects were:

Dr. Bruer, The Physician as a Health Educator  
Dr. Augustus G. Pohlman, Omaha, The Physiology of the Changes in the Circulatory System at Birth  
Dr. Chester A. Stewart, Minneapolis, Treatment of Epilepsy in Children  
Dr. Harry L. Smith, Rochester, Minn., Syncope of Patients with Hypersensitive Carotid Reflexes  
Dr. William H. Olmsted, St. Louis, Present Day Diabetic Diets  
Dr. Roland M. Klemme, St. Louis, Diagnosis and Treatment of Intracranial Lesions  
Dr. Ferdinand C. Helwig, Kansas City, Kan., Radiosensitivity and Radioresistance in the Therapy of Malignant Disease  
Dr. Meyer Wiener, St. Louis, Eye Findings and Their Interpretation in Intracranial Lesions  
Dr. Ray M. Balyeat, Oklahoma City, The Therapeutic Value of Intratracheal Iodized Oil as an Adjunct in the Treatment of Intractable Asthma

The banquet Tuesday evening was addressed by Dr. Stewart and Dr. Roger L. J. Kennedy, Rochester, Minn., on "Prevention and Treatment of Tuberculosis" and "Some Diseases in Children Accompanied by Changes in the Skeleton and Extraskeletal Tissues," respectively. The banquet session Wednesday evening was a joint meeting with the Buchanan County Medical Society. Speakers were Drs. Olmsted on "Physiology of Bulky Foods in the Treatment of Constipation," Dr. Klemme, "Diagnosis and Accurate Differential Section in the Treatment of Trigeminal Neuralgia," and Dr. Duff S. Allen, St. Louis, "Some Newer Aspects in Surgery of the Thyroid."

### NEW HAMPSHIRE

**State Medical Meeting in Manchester**—The one hundred and forty-fifth annual meeting of the New Hampshire Medical Society will be held at the Hotel Carpenter Manchester, May 26-27, under the presidency of Dr. Clifton S. Abbott, Laconia. Physicians presenting the program will include:

Joseph Dunbar Shields, Jr., Concord, The Irritable Colon: Diagnosis and Treatment by the General Practitioner  
John D. Spring, Nashua, Arterial Pneumothorax in the Treatment of Tuberculosis  
Henry A. Christian, Boston, Diuretics and What They Do  
M. Dawson, Tyngsboro, Problems in the Diagnosis and Treatment of Bronchiectasis  
Jesse O. Arnold, Philadelphia, More Rational Methods in the Prevention and Control of Eclampsia  
Morris Fishbein, Chicago, Public Relations of the Medical Profession  
Oswald S. Lowis, New York, Recent Advances in Urologic Surgery Including Renal and Prostatic Surgery  
Experiences with a New Operation for Impotence  
William D. Stroud, Philadelphia, Coronary Disease Including Angina Pectoris

A symposium on pediatrics will be conducted Tuesday afternoon by Drs. Richard M. Smith, William E. Ladd and Richard Cannon, all of Boston. On the same day Dr. Ellen A. Wallace, Manchester, will be presented with the fifty-year membership gold medal. The annual banquet Wednesday evening will be addressed by Governor H. Styles Bridges, Dr. Abbott and Dr. Fishbein.

### NEW JERSEY

**Society News**—Drs. Burgess L. Gordon and Paul A. Bishop, Philadelphia, addressed the Camden County Medical Society, Camden, April 7, on "Tuberculosis in Childhood and the Teen Age" and "X-Ray Diagnosis" respectively. Dr. George F. Pfahler, Philadelphia, addressed the Atlantic County Medical Society, Atlantic City, April 10, on "Treatment of Carcinoma of the Bladder." The Society of Surgeons of New Jersey will hold its spring clinical meeting at Orange, May 27, with clinics at the Orange Memorial Hospital, golf in the afternoon and dinner at the Essex County Country Club, West Orange. Benjamin Werne, editor of *Current Legal Thought*, addressed the Bergen County Medical Society, Hackensack, April 14, on "The Role of Medical Science in Preventive Justice." Dr. Harry H. Satchwell, Irvington, addressed a joint meeting of the county societies of the first and second districts of the Medical Society of New Jersey at Newark, April 9, on "Medical Economic Security."

### NEW YORK

**Woman's Auxiliary Organized**—Wives of members of county societies met at the Waldorf-Astoria, New York, March 11 to organize the Woman's Auxiliary to the Medical Society of the State of New York. Mrs. John L. Bauer, Brooklyn, was elected president, Mrs. Francis R. Irving, Syracuse, president elect, Mrs. Edward A. Flemming, Brooklyn, and Mrs. Frederic E. Elliott, Brooklyn, vice presidents. Mrs. Henry L. Hirsch, Rochelle Centre, secretary, and Mrs. Daniel J. Swan, Flushing, treasurer. Dr. Frederic E. Sondern, New York, president of the state society, addressed the organization meeting.

**Society News**—Dr. William Snow, New York, addressed a joint meeting of the Onondaga Medical Society and the Syracuse Eye, Ear, Nose and Throat Club, March 3, on "Topical Treatment of the Upper Respiratory Tract" and "Mechanical Factors in Acute Pulmonary Disease of Infants." Dr. Russell L. Cecil, New York, addressed the Warren County Medical Society, Glens Falls, March 6, on "Newer Methods of Diagnosis and Treatment of Pneumonia." The New York State Association of Public Health Laboratories will hold its twenty-first annual meeting at Vassar College, Poughkeepsie, May 25. Dr. Warfield T. Longcope, Baltimore, addressed the Syracuse Academy of Medicine, March 17, on "Pyelonephrosis."

### New York City

**Fellowship for Study of Emotions**—The Rockefeller Foundation has provided a research fellowship at the British Institute of Medical Psychology, London, beginning March 1. It is for research into the relation between the emotional and organic factors in certain physical disorders, *Science Reports*.

**Lord Horder Gives Janeway Lecture**—Lord Thomas Jeeves Horder, senior physician to St. Bartholomew's Hospital, London, will deliver the Edward Gamaliel Janeway Lecture, May 15, on "Direct Action in Medicine." The lecture will be given in the Blumenthal Auditorium, under the auspices of Mount Sinai Hospital of New York.

**Medical Care for Relief Clients**—More than 81,500 home relief families required medical care in the three months between Dec. 15, 1935, and March 15, the Emergency Relief Bureau has reported. The number of cases was highest in February, when all records were broken with 33,400. Less than 10,000 needed care in the last half of December, 24,000 in January and 14,000 in the first half of March. During the three months there were about 56,000 assignments of physicians registered with the bureau and 4,200 nurses' visits, 152,000 prescriptions and 4,000 surgical and optical appliances were issued.

**New Agency to Deal with Delinquent Children**—Mayor La Guardia has recently set up in the Children's Court of Manhattan a new agency known as the bureau of adjustments to which delinquent children will be referred for study with a view to adjusting their problems without recourse to the courts. The new bureau is the first step in a program to be administered under a newly created Inter-Departmental Coordinating Board for Child Welfare, made up of representatives of eight branches of the city government, headed by Justice John Warren Hill of the Court of Domestic Relations. It will be the task of the board to coordinate the activities of all city departments having to do with child problems. Among the members of the board are Drs. Karl M. Bowman, head of the psychiatric division of the hospital department, and George T. Palmer, Dr. P.H. assistant health commissioner. A committee headed by C. C. Burlingham will coordinate the work of the new board with private agencies in the same field. It is planned to open bureaus of adjustment in all five boroughs.

## NORTH CAROLINA

**Society News**—Dr William D Stroud, Philadelphia, addressed the Guilford County Medical Society, April 2, on 'Coronary Disease'—The Tri-State Hospital Conference of North and South Carolina and Virginia was held in Richmond, April 16-17—Drs Robert P Noble and Robert H Hackler Jr Raleigh, addressed the Wake County Medical Society March 12, on 'X-Rays in Treatment of Skin Disease' and 'Physical Characteristics of X-Rays and Their Clinical Application' respectively—Dr Emil Novak Baltimore addressed the society, April 8, on 'The Endocrines in Gynecologic Practice'—At the semiannual meeting of the Eighth District Medical Association in Mount Airy, April 8 speakers included Drs Charles O Delaney Winston-Salem, on 'Treatment of Acquired Renal Dystrophia' Carl V Tyner, Leaksville, 'Leukorrhea,' and Samuel F Ravenel Greensboro 'Advances in Prevention and Treatment of Contagious Diseases'—Dr William D James Hamlet discussed cancer prevention at a meeting of the Rutherford County Medical Society, Forest City, April 16

## OHIO

**Hospital News**—Typing service for the pneumonias and demonstration of the method of typing by the Neufeld technic have been made available to physicians of Hamilton County at the Cincinnati General Hospital, through the generosity of an anonymous donor, it is announced For indigent patients specific therapeutic serum will be donated—Cameron Hospital a \$40,000 structure with a capacity of twenty-five beds was opened April 5 at Bryan

**Conference of County Officers**—The council of the Ohio State Medical Association has invited officers of all county medical societies with chairmen of their medical economics public relations and legislative committees to meet with officers of the state association for a conference in Columbus, April 26 Subjects to be discussed include medical care of the indigent legislative problems and developments workmen's compensation the social security program in Ohio promoting county medical society attendance and programs

**District Meeting**—The second councilor district of the Ohio State Medical Association held its annual meeting in Springfield, April 15 Guest speakers at an afternoon session were Drs Albert M Snell, Rochester, Minn, who discussed 'Recent Studies in the Liver and Biliary Tract and 'Clinical Observations,' and George M Curtis, Columbus Iodine as Related to Thyroid Disease' and Enlargements of the Spleen' Dr Morris Fishbein, Chicago, editor of THE JOURNAL gave the address at the annual banquet at the Shawnee Hotel The morning was devoted to clinics at the Springfield City Hospital

## PENNSYLVANIA

**New Appointments to Advisory Health Board**—The following appointments to the state advisory health board were announced by Governor Earle April 10 Dr Moses Behrend Philadelphia succeeding Dr Ross V Patterson, Philadelphia Dr Richard J Behan Pittsburgh, succeeding Dr William G Turnbull, Philadelphia Dr Erwin S Briggs Warren succeeding Dr John M Beck Alexandria Dr Walter S Brenholtz Williamsport, succeeding Dr Saylor J McGhee, Lock Haven, and John A Meehan DDS, New Castle

## Philadelphia

**Alumni Luncheon**—The Medical Alumni of the University of Pennsylvania will join in a luncheon at the Hotel Pennsylvania, Saturday, May 16 Dr Charles W Burr Philadelphia is president

**Packard Lecture**—Dr Clifford G Grulee clinical professor of pediatrics Rush Medical College Chicago delivered the annual Frederick A Packard Memorial Lecture of the Philadelphia Pediatric Society April 14 Dr Grulee's subject was Intracranial Hemorrhage of the New-Born

**Dr Brumm Receives Strittmatter Award**—Dr Seth A Brumm received the thirteenth Dr I P Strittmatter Award at the annual dinner and meeting of the Philadelphia County Medical Society, April 22, in recognition of his accomplishments in the activities of organized medicine Dr Brumm who is 54 years of age graduated from the University of Pennsylvania School of Medicine in 1906 He was president of the county medical society for the year that began July 1 1934 He was appointed chief of the division of communicable diseases of the Philadelphia Department of Health in 1932 and

in the same year elected president of the Philadelphia Association of Tuberculosis Clinics Dr Frank H Laher, Boston delivered the Dr John Chalmers DaCosta Oration on 'Management of Biliary Tract Disease'

## TENNESSEE

**Society News**—Dr Andrew A Eggston, New York, addressed the Nashville Academy of Medicine April 21 on 'Clinical Pathology in Relation to Diagnosis' Richard E Scammon Ph D Minneapolis addressed the academy, April 7 on 'The Guild of Medicine'—A symposium on heart diseases was presented before the Hamilton County Medical Society, Chattanooga, April 30, by Drs Philip H Levinson Harold J Starr Howard P Hewitt, Ashby M Patterson and Frederick E Marsh—Dr Homer Stirl Rule Jacksboro addressed the March meeting of the Campbell County Medical Society, LaFollette on history, incidence and diagnosis of syphilis—Dr Elbert G Wood Knoxville addressed the Knox County Medical Society, April 7, on 'Toxemia of Late Pregnancy'

## TEXAS

**State Medical Meeting in Houston**—The seventieth annual session of the State Medical Association of Texas will be held in Houston May 26-28, under the presidency of Dr John H Burleson, San Antonio with headquarters at the Rice Hotel The program includes the following guest speakers

Eugene T Leddy Rochester Minn Roentgen Ray Treatment of Severe Asthma  
Edward William Alton Ochsner New Orleans The Physiologic Treatment of Peptic Ulcer  
Marcus Pinson Neal Columbia Mo The Reactive Blood Cells in Acute Infections  
Edward H Ryneanson Rochester Minn Syndromes Resulting from the Hypofunction and Hyperfunction of the Endocrine Glands  
Charles J Bloom New Orleans Thyrotoxicosis in Children  
Gershom J Thompson Rochester Minn Urinary Lithiasis  
Lawrence M Randall Rochester Relief of Pain During Labor  
Oscar B Nugent Chicago Interesting Facts About the Eyes  
Winfield K Sharp Jr New Orleans The Social Security Act As It Relates to Public Health in Texas

Memorial services will be held Wednesday Related organizations meeting at this time include the Texas Railway Surgeons Association, Texas Neurological Society, Texas State Heart Association, the Conference of County and City Health Officers and the Texas Dermatological Society

## VIRGINIA

**Faculty Changes at Medical College**—The Medical College of Virginia Richmond, recently made the following promotions for the session of 1936-1937 Rolland J Main, Ph D to be associate professor of physiology Drs William D Suggs, assistant professor of obstetrics, and Lawther J Whitehead assistant professor of radiology Dr William L Peple, resigned, was made emeritus professor of clinical surgery

**Personal**—Dr Thomas M Parkins, coroner of Staunton has been appointed health officer to succeed Dr James Fairfax Fulton—Maximilian Ehrenstein Ph D research fellow in physiology, University of Virginia Department of Medicine has been awarded one of the prizes of the van Hoff Fund by the Royal Academy of Sciences at Amsterdam, in recognition of his work on the alkaloids of tobacco and the catalytic dehydrogenation of cyclic bases

## WASHINGTON

**Increase in the Death Rate**—The mortality rate for Washington in 1935 was 112 per thousand of population compared with 109 in 1934 the state health department reports It is reported that of 18,217 deaths 4751 were caused by diseases of the circulatory system 2233 by cancer and other tumors 1518 by cerebral hemorrhage and 1524 by diseases of the genito-urinary system Deaths from automobile accidents declined by forty from 1934 the number for 1935 being 570 The infant mortality rate increased from 432 in 1934 to 451 for last year Deaths of mothers in childbirth numbered 117 ten higher than in 1934

**Society News**—Drs Charles P Wilson and Arthur J McLean, Portland addressed the Cowlitz County Medical Society, Longview in March on Diagnosis and Treatment of Rheumatism and Spinal Injuries respectively—Dr George W Swift Seattle addressed the Spokane County Medical Society, Spokane in March on Spinal Drainage in Treatment of Head Injuries—Drs George R Marshall Seattle and Kenneth K Sherwood Kirkland addressed the Yakima County Medical Society in March on 'Proctologic Examinations and

'Chronic Arthritis' respectively—Dr Jackson K Holloway, Seattle discussed inguinal hernia with report of a case of hydrocele of the canal of Nuck before the King County Medical Society May 4, and Dr Kenneth K Sherwood Kirkland 'Natural Course of Post-Traumatic and Gonorrheal Arthritis' The society was addressed, April 20, by Drs Homer D Dudley and Hilton W Ro e, Seattle, on 'Sacculated Varix of the Femoral Vein' and 'Cool Water Treatment of Burns' respectively

### WISCONSIN

**Personal**—Dr Ethan B Pfefferkorn, Oshkosh, has been appointed assistant state health officer to succeed Dr Guy W Henka, Madison—Dr Adolf Gundersen La Crosse, and Mr J George Crownhart, Madison, secretary, State Medical Society of Wisconsin, are members of a committee recently appointed by Governor La Follette to study administration of relief, federal aid and state institutions

**Digest of Laws on Care of Indigent Sick**—The State Medical Society of Wisconsin, through its department of legal medicine, has recently issued the sixth edition of a "Summary of Wisconsin Poor Relief Laws Affecting Care of Indigent Sick" The pamphlet contains excerpts from the statutes and statements of principles drawn from court decisions attorney generals' decisions and other available authorities Thirty-two questions are dealt with, including authorization of relief, definitions of the indigent, emergency relief, the physician's problem with persons obviously indigent but not able to get relief, obstetric cases malpractice hospitalization of various kinds, care of the handicapped and pensions It closes with a resolution adopted by the state board of health February 27, urging counties cities, villages and towns to maintain an adequate medical relief program to take the place of that financed until recently by federal funds Three points were emphasized by the board right of the sick to have the physician of their choice, continuation of the manner of recompense used under the federal program and a policy of reasonable hospitalization when found essential to the welfare of the patient by the family physician

### GENERAL

**Change in Date of Library Meeting**—The annual meeting of the Medical Library Association will be held in St Paul, June 22-24 instead of May 25-27 in Rochester as previously announced

**Medical Bill in Congress**—*Bill Introduced* H R 12492 introduced by Representative Couden, California, proposes to authorize an appropriation of such sum as may be necessary not to exceed \$2,000,000, to construct a marine hospital at Los Angeles Harbor Los Angeles for the accommodation of approximately 500 bed patients

**Winners in City Health Contest**—Detroit Oakland, Syracuse, Schenectady, Brookline and Hibbing are the winning cities in the seventh annual interchamber health conservation contest conducted among cities by the Chamber of Commerce of the United States in cooperation with the American Public Health Association The city contest supported by a group of insurance companies is to determine which municipalities of various populations are carrying on the most effective community public health programs, in an effort to prevent premature deaths and economic losses due to unnecessary illness

**Orthopedic Meeting**—The fiftieth annual meeting of the American Orthopedic Association will be held in Milwaukee May 18-21, under the presidency of Dr Frederick J Gauslen Headquarters will be at the Hotel Schroeder Speakers will include

Dr Richard B Dillehunt Portland Ore Reconstruction of Injured Elbows in Children  
Dr William C Turner Montreal Quebec Fractures and Fracture Dislocation of the Cervical Spine  
Drs Marius N Smith Petersen and Paul L Norton Boston Treatment of Bursitis  
Dr Henry W Neveding Rochester Minn Treatment of Giant Cell Bone Tumors  
Dr Elen J Carey Milwaukee The Wave Mechanics of Muscle Motion  
Dr Zabdil B Adams Boston Occurrence of Abscesses from Hips That Are Firmly Ankylosed

**Research Conference**—The departments of biology chemistry and physics of Johns Hopkins University will hold a research conference at Gibson Island near Baltimore, June 22-July 24 The tentative program gives the following topics for discussion nuclear physics photochemistry tissue respiration, chemistry of olefins from petroleum and synthetic resins The plan is flexible varying from day to day according to the nature of the topic under discussion and the wishes of

those participating A somewhat formal lecture will open the day's program, outlining some field of research and directing attention to its unsolved problem, and will be followed by a discussion in which each one present takes part making what contribution he can to the solution of the problems presented The conferences are intended to combine mental stimulation pleasant personal contacts and healthful recreation Further information may be obtained from Neil E Gordon, department of chemistry, Johns Hopkins University, Baltimore

**Association for Study of Internal Secretions**—The twentieth annual meeting of the Association for the Study of Internal Secretions will be held at the Hotel Baltimore, Kansas City, Mo, May 11-12 Speakers will include the following

Roland K Meyer Ph D and Dr Elmer I Sevringhaus Madison Wis Gonadotropic Inhibitory Substances in Blood of Women and Monkeys After Anterior Pituitary Therapy  
Edward A Doisy Ph D St Louis Isolation of One of the Active Principles of the Ovary  
Dr Hector Mortimer Montreal Hormone Relationship Between the Female Organs of Sex and the Nasal Mucous Membrane  
Dr Hans Lissner San Francisco Two and One Half Years Observation of a Patient with Cushing's Disease Following Removal of a Pars Intermedia Adenoma  
Dr James B Collip Montreal, Further Studies in Anterior Pituitary Physiology

At the annual dinner, Monday evening, Dr Francis M Pottinger, Monrovia, Calif, will deliver the presidential address and Dr Roy G Hoskins, Boston, will speak on "Broader Aspects of Endocrinology"

**Eastern Physical Therapy Meeting**—The spring session of the eastern section of the American Congress of Physical Therapy will be held at the Philadelphia County Medical Building Philadelphia, May 27-28, under the presidency of Dr William H Schmidt The following physicians will present papers

John de P Currence New York Physical Therapy in the Treatment of Arthritis  
Jerome Weiss Brooklyn Physical Therapy in Orthopedic Conditions  
Midge C L McGuinness New York Danger of Over-treatment in Physical Therapy  
William Bierman New York president elect of the congress Temperature of the Surface of the Skin  
Gervase J P Barger Washington D C Fever Therapy in Office Practice  
Norman E Titus New York Treatment of Erysipelas with Ultra violet Energy

A joint meeting with the Philadelphia County Medical Society, Wednesday evening, will be addressed by Drs Eugene M Landis and Lewis H Hitzrog, Philadelphia, on 'Evaluation of Suction Pressure in Peripheral Vascular Disease' and Dr Disraeli W Kobak, Chicago, "Influence of Short Wave Radiation on Constituents of the Blood" All day Thursday will be devoted to clinics

**Symposium on Atmospheric Environment**—The Harvard School of Public Health, Boston, will conduct a symposium on the atmospheric environment and its effect on man, August 24-29 One day will be devoted to the pneumoconoses with the following speakers

Mr Philip Drinker associate professor of industrial hygiene Harvard School of Public Health Etiology  
Dr William Irving Clark assistant professor of the practice of industrial medicine Clinical Aspects Diagnoses Prevention  
Mr Theodore F Hatch instructor in industrial sanitation Harvard Schools of Engineering and of Public Health Control  
Mr J J Bloomfield sanitary engineer, U S Public Health Service Protective Equipment

Subjects to be discussed will include physical fitness for industrial and office jobs, fatigue, occurrence and significance of gaseous impurities nontoxic odors in ventilation, and air condition in normal life Speakers will include the following members of the Harvard faculty Dr Arlie V Bock, Oliver professor of hygiene, David B Dill, Ph D assistant professor of biologic chemistry Dr Wilson G Smillie, professor of public health administration Mr William F Wells instructor in sanitary science Dr Cecil K Drinker professor of physiology and dean Lawrence T Fairhall, Ph D assistant professor of physiology, Mr Constantin P Yaglou Mr Louis A Shaw assistant professor of physiology Additional speakers will be Mr William P Yant, supervising chemist health laboratory section and supervising engineer, Pittsburgh Experiment Station U S Bureau of Mines, Mr Ole Singstad chief consulting engineer on tunnels, Port of New York Authority, and Dr Wolfgang F von Oettingen director Haskell Laboratory of Industrial Toxicology Wilmington Del The symposium will be concluded with a demonstration in the school of public health and visits to the industrial clinic Norton Company Worcester, Mass the Fletcher Granite Company, West Chelmsford Mass and the Fatigue Laboratory of Harvard Business School

### LONDON

(From Our Regular Correspondent)

March 28, 1936

#### John Scott Haldane

Prof John Scott Haldane, FRS, physiologist and philosopher, has died at his home in Oxford at the age of 75. Born at Edinburgh, he was educated at the university and also studied at Jena. He graduated in medicine in 1884 and became a demonstrator at the University of Dundee, where in collaboration with Professor Carnelly he made an extensive investigation of the inorganic impurities of the air of dwellings, schools and sewers. This was published in 1887, only three years after he was qualified, showing his early interest in the physiology of respiration, on which he became the greatest authority in the world, making discoveries which revolutionized our knowledge. Soon afterward he became demonstrator in physiologic chemistry at Oxford to his uncle Sir John Burdon Sanderson, the physiologist. He remained at Oxford for the rest of his life and carried out there researches of fundamental importance in physiology and also of great practical use. He investigated impurities of the air in mines and discovered the action of carbon monoxide, the poisonous constituent of after-damp. He introduced simple tests by which small though dangerous quantities of carbon monoxide could be detected, using small animals, such as birds and mice, which are affected more quickly than man. In 1896 he investigated for the government the cause of death in three colliery explosions. His report, which was translated into several languages, showed the means for combating in mines the dangers arising from explosions and fires.

Between 1892 and 1900 he introduced new methods for investigating respiratory functions which are widely used today—methods for determining the respiratory exchange, the amount of hemoglobin in the blood, the volume of the blood and the analysis of air. In 1905 he published (in association with Dr Priestley) his most important discovery, that respiration is regulated by the tension of carbon dioxide in the arterial blood in the respiratory center, to which it is exquisitely sensitive. He thus gave the first insight into the extraordinary delicacy of the quantitative coordination of the activities of different parts of the body by chemical means. A few years later it was shown that carbon dioxide acted by diminishing the alkalinity of the blood. In 1905 he demonstrated the importance of wet bulb temperature in limiting the power to withstand a high temperature. In 1911 he led an expedition to Pike's Peak, Colorado, to study the effects of low barometric pressure and acclimatization to high altitudes. For the admiralty he investigated the problem of deep diving and showed how the risks of caisson disease could be abolished. In the war he was sent to the front as soon as poison gas was used by the Germans. His advice led to the adoption of the box type of respirator—the only adequate one.

#### HALDANE'S PHILOSOPHY

So far Haldane has been described as a great physiologist, but he had another side—the philosophical—which distinguishes him from all other physiologists. His philosophical bent was due to his Scotch blood. His brother Lord Haldane, lawyer and statesman, was also well known as a philosopher. Haldane's philosophy was not a diversion from his physiology but was intimately connected with it and indeed inspired his researches. Ever since he was a young man he combated the mechanistic theory of life, which is current among biologists and is widely spread by popular writers. He insisted that while a physicochemical interpretation of life had endless prac-

tical uses it was only a partial one, derived from abstracting certain aspects and neglecting the others. It ignored coordination which was the dominant feature of life. The organism must be studied as a whole. All his work showed the amazing delicacy with which the different functions of the body are correlated in normal life. Biology he regarded as an independent science with different axioms and different methods of interpretation from those of chemistry and physics. He quoted the physicist Planck. "The conception of wholeness must be introduced into physics as into biology." Thus mathematical physics could be regarded as a backward branch of biology, in contrast to the view of some scientists that biology is only a complicated and therefore backward branch of mathematical physics. He pointed out the difficulty which confronted the mechanistic conception of life—that of giving any account of the maintained coordination which is so characteristic. "We can form no coherent mechanistic conception of how it is that the intensely labile living structure tends to return always to normality, how the breaking down process is so coordinated that the building up process accompanies it. Maintenance of normality is a fact present in all physiological activity and cannot be analyzed into separable physicochemical processes."

He held that the confusion caused by failure to distinguish biology from physical science was repeated when there was failure to distinguish psychology from biology. In conscious behavior there was something different from mere life, in which the unity extended only over spatially related phenomena. In conscious behavior the unity extended also over temporal relations, the past and the future were unified with the present by the interest which extended over them. Biology could not deal with personality or values, the science that dealt with them was psychology, which dealt with conscious experience. All our knowledge of the universe implied perception. In the natural sciences we did not directly consider this, but in psychology we had to. We could not jump out of our skin of perception to a world beyond it. An analysis of what is implied in perception would embrace all knowledge and so he reached the idealistic doctrine of Berkeley. All his life he strenuously combated materialism as an impossible philosophy. For him the universe was a universe of personality and the manifestation of God. But he rejected the usual religious view that a spiritual universe exists side by side with a physical one. He was thus a deeply religious man, who could not accept any of the religious creeds. Yet, because of his strong antagonism to materialism he was in demand as a lecturer by religious bodies. One of his last books, "Materialism" consists of a series of essays, some of which were delivered as lectures. It is noteworthy that one of these was delivered at a church and another at a synagogue. One might say of other physiologists that they were either materialists or never troubled about the question of materialism. But to Haldane materialism was an absurdity and the spiritual nature of the universe a fundamental doctrine, which he never was tired of teaching. In the last twenty years Haldane wrote and lectured much more on philosophy than on physiology, but his biologic approach to philosophy, as well as the position he took up distinguished him from other philosophers. This work culminated in a small book 'The Philosophy of a Biologist,' published in 1935. Recent British philosophy can be described as 'idealism' in contrast to 'realism' which regards physical interpretation as a final interpretation of external reality. In this sense and in this sense only Haldane's philosophy was idealistic. But in a deeper sense it was wholly realistic as he regarded the universe as depicted in the sciences not as a mere appearance but as the real universe imperfectly depicted. He summed up his philosophy thus: 'The real universe is a universe of personality and the manifestation of God its scientific aspects being only partial interpretations of it the imperfect nature of which is revealed by philosophic criticism.'

### The Society for the Protection of Science and Learning

The Academic Assistance Council was formed in 1933 to assist scholars and scientists who on grounds of religion, race or opinion were unable to work in their own country. After doing excellent work it has decided to establish as its permanent successor the Society for the Protection of Science and Learning. It is proposed to build up an academic assistance fund for the purpose of awarding research scholarships in the universities of Great Britain and other countries. The fund will be administered under the auspices of the archbishop of Canterbury, the president of the Royal Society and the president of the British Academy, Lord Rutherford and Lord Horder. In an appeal for funds Lord Rutherford, who was president of the Academic Assistance Council, states that its services have been needed chiefly for 1,300 university teachers displaced in Germany, but it has also assisted refugee scholars from Russia, Portugal and other countries. In cooperation with other organizations the Council has assisted in permanently establishing 363 of the 700 displaced scholars who left Germany. A further 324 are still being temporarily maintained in universities and learned institutions while seeking more permanent positions. The council had hoped that its work might be required for only a temporary period but it is now convinced of the need for a permanent body to assist scholars the victims of political and religious persecution. The devastation of the German universities still continues. Not only teachers of Jewish descent but many others regarded as "politically unreliable" are affected. The appeal is being made with the full cooperation of the organizers of the national Christian appeal about to be made for destitute non-Jewish refugees from Germany, since the society will assist refugees irrespective of their religious affiliations. Support is therefore asked from both the Christian and the Jewish world, and in particular from the university world.

### Voluntary Prenuptial Examination

Certificates of health before marriage have been advocated and every gradation exists from compulsory measures, such as exist in Germany and Turkey, and a purely voluntary measure, which is now suggested by the Eugenics Society. A committee of this society, mainly well known physicians, has prepared a schedule for the use of the physician in the examination. Two purposes might be served by such a schedule. The first which is mainly in view in Germany, is to prevent the birth of defective children. The second is to promote the happiness of marriage by the early detection and treatment of such physical or psychologic abnormalities as might militate against the success of the marriage. The Eugenics Society states that its schedule is the only one in existence which serves both purposes. It includes questions not only on medical history but on psychologic and sexual problems which often present themselves to those about to marry. Many of these difficulties can be reduced or even removed by a frank talk with a physician.

The society advises that a person who wishes to be examined before marriage should approach his family physician. The society sends its schedule only to physicians who ask for it. If a physician desires an opinion on a problem of heredity arising from a doubtful family history, the society will help him through a board of specialists appointed for the purpose.

The schedule consists of three parts. Part I is devoted to family history and goes back as far as the grandparents. It includes questions as to cases of nervousness, nervous breakdown, mental backwardness, insanity, fainting spells, convulsions, suicide, alcohol and drug addiction, tuberculosis, diabetes, asthma, blindness or deafness in early life or any disease thought to be inherited. Part II is devoted to previous medical history and includes the usual questions of life insurance

schedules. But there is a section on possible sexual problems. The applicant is asked simply to answer yes or no to the questions "Do you understand fully the physical differences between the sexes, the nature of the sex act and the use of birth control? Is the subject of sex at all repugnant to you? Are you aware of any abnormal tendencies, fears or desires in your sex nature?" Women are asked if they understand about pregnancy or childbearing and whether they have any fear about this. Any difficulties about sex matters should be discussed with the physician. Part III is devoted to physical examination and is to be retained by the physician and not shown to the applicant. It consists of the usual questions for life insurance but includes abnormalities of the sex organs, sexual deviation and the Wassermann reaction.

Finally the following advice is given to the examining physician. The schedule is only for his use. If he has any difficulty he can refer it to a consultant. The society can help him only as regards a genetic problem. No opinion as to the success of a prospective marriage is infallible and this should be emphasized to the applicant. The marriage of first cousins is to be discouraged if there are in the common ancestry any defects or disease not due to environment. But with a good ancestry a marriage between cousins is not contraindicated. Neurotic persons are often preoccupied with sexual difficulties and frank discussion with the physician may be beneficial. Difficulties with regard to masturbation usually disappear after marriage. A homosexual phase is common in the adolescence of both sexes, but the predominance of homosexual impulses in the adult is a serious matter.

### Is Silicosis an Occupational Disease?

The pneumoconiosis problem is of great importance at present not only to departments of public health but also to those interested in hygiene. In spite of intensive study during recent years there is much to be learned regarding which forms of mineral dust are harmful, the clinical manifestations, and the relation of the disease to pulmonary tuberculosis.

At the February 18 meeting of the Académie de médecine the results of a thorough study of the question as it affects coal miners in Holland were presented by Vossemar of Heerlen and Doubrow of Paris. The study was based on roentgenograms of 600 men who had been employed for more than ten years as coal miners. Sixty, or 10 per cent, had been engaged in this work for more than twenty years. This study led to the conclusion that no clinical or roentgenographic evidence of pulmonary sclerosis can be obtained in normal individuals employed over a prolonged period in an atmosphere charged with dust containing silicates. There is no relation between the period at which the abnormal roentgenographic signs appear and the length of time the individual has been exposed to silicosis. Roentgenographic shadows similar in every respect are found in individuals suffering from pulmonary tuberculosis who have worked in silicate dust. It is probable that bacterial infection can cause chronic pneumopathies in those working in a dust-laden atmosphere among such pneumopathies, tuberculosis is undoubtedly the most important and the most frequent. Dust in industrial occupations, from the standpoint of hygiene in general, constitutes a danger, even if the dust has no specific pathogenic action that ought to be combated by appropriate technical measures. There would, however, be only illusory unless associated with a rational antituberculosis campaign.

In the discussion, Rist stated that the view that silicosis is a clinical entity, i. e., a primary autonomous disease has been generally abandoned. A silicosis will not affect a lung that is

not already diseased, the pathologic condition in the majority of cases being tuberculosis. Some miners can go for as long as twenty five years in a dust-laden atmosphere without developing any lung complications. On the other hand, one finds individuals who have never worked in a mine but who present roentgenographic signs that have been too hastily interpreted as being characteristic of silicosis and furthermore not to be distinguished from images seen in pulmonary tuberculosis. South African observers have found that those who have a supposed silicosis always die of tuberculosis. There is such a close relation between silicosis and tuberculosis that it is impossible at present to state in a given case whether there is a so called pure silicosis or a silicosis associated with a pulmonary tuberculosis. Hence the difficulty existing in France and foreign countries in placing in the list of occupational diseases a syndrome so ill defined with regard to its character, cause and diagnosis as is silicosis.

Crouzon stated that this subject had been discussed at several meetings of the Medicolegal Society and that many different opinions were expressed. Certain authors think that silicosis per se can assume a role in the etiology of certain bronchopulmonary disorders and hence ought to be considered as an occupational disease. The result has been that silicosis is so regarded in France, a step which Rist believes was taken too hastily. Another group believes that the pathogenic role of silicosis is too little known at present. Pollet maintains that from the standpoint of indemnity and legal responsibility, if silicosis gives rise to a bronchopulmonary infection, silicosis must be regarded as an occupational disease. The Medicolegal Society therefore voted in favor of a more extensive study of the subject as to which victims of silicosis are entitled to be regarded as having an occupational disease. As a result of this discussion the Academy of Medicine named a special commission to investigate the question whether silicosis should be regarded as an occupational disease.

#### Pneumectomy for Cancer of the Lung

Pneumectomy for cancer of the lung is being actively discussed in France. It has been chosen as the subject of a report to be made at the next annual surgical congress, to be held in October. At the February 7 meeting of the Société médicale des hôpitaux of Paris a case was reported by Ameuille and his associates in which an unsuccessful attempt was made by Menegaux to perform a pneumectomy (right lower lobe) for cancer. The obstacles that have prevented more rapid development in this field of cancer surgery are difficult and too late diagnoses and inability to estimate the extent of adhesions and lymph node extension. Bronchoscopy is of some help in the diagnosis of a primary bronchial cancer but of no aid in the diagnosis of a primary invasion of the lung itself. In many cases only an exploratory thoracotomy will enable a diagnosis to be made. Such an operation can be followed by a pneumectomy and high voltage roentgen or radium therapy. In every case one should have as complete information as possible as to invasion of the cervical and axillary lymph nodes. In addition, an x-ray examination of the mediastinum should be made in conjunction with the use of opaque mediums in the trachea and esophagus in order to exclude invasion of these structures. An artificial pneumothorax followed immediately by fluoroscopy of the chest yields much information as to the presence and extent of adhesions, especially if any pleuritic exudate has been aspirated as a preparatory measure. Before attempting a pneumectomy, one must explore the condition of the other lobe or lobes of the lung, of the mediastinum, of the diaphragm and of the chest wall.

In the discussion, Justin-Besançon stated that progress in this field of surgery could be achieved only if an early diagnosis is made. Monod believed that the reason why there have

been no cures so far in France is that the diagnosis is made too late. In a personal case a two-step operation was done. The tumor was between the aorta and the pulmonary artery, so that hemostasis was impossible. In another case operation was possible even though there was an invasion of the mediastinum. The patient died suddenly two days later. Both of these operations were performed too late.

#### Acquired Natural Immunity Against Tetanus

The presence of tetanus antitoxin has been investigated in hundreds of serums by Ramon and Lemetayer, who have reported their results in the *Revue d'immunologie*. Specimens of blood were obtained from human beings and from different species of ruminants in Europe, Asia and Africa as well as from horses, pigs, dogs and laboratory animals. The serum of ruminants contains tetanus antitoxin in more or less abundance according to their age, habits and mode of life. The serum of human beings, horses, dogs, pigs and laboratory animals does not contain a trace of the antitoxin. These facts explain the rarity of tetanus in adult ruminants and its frequency in the others just named. The authors believe that this acquired immunity in ruminants is due to the fact that the tetanus bacillus enters the body with the food, with resultant production of toxin, which in turn is attenuated by the products of fermentation of other bacteria and results in the elaboration of an antitoxin in the serum.

#### Streptococcic Infections Treated with Vincent Serum

At the meeting of the Académie de médecine, January 21, Professor Vincent reported a case of meningitis treated by Hamon and Bolzinger. This is the eighth case of meningitis, due to hemolytic streptococci, cured by serotherapy. The patient, a man of 20, had such a severe attack of meningitis of otitic origin that a fatal issue was feared. The Vincent antistreptococcus serum was given intravenously and by lumbar puncture. The organism disappeared from the spinal fluid following the serotherapy supplemented by mastoidectomy.

Before the Académie des sciences, Oct 21, 1935, Professor Vincent stated that the invasion of the blood stream is governed by two essential conditions. The first depends on the state of allergy of the individual, the second on the fact that the streptococcus finds in the blood serum a medium little favorable to its growth and thus strains of streptococci develop that are seroresistant. There are at present reports of 310 cases of streptococcic cerebrospinal meningitis and septicemia treated by the Vincent serum, with 252 recoveries and fifty eight deaths. This is a proportion of 81 per cent cures and a mortality of 18.70 per cent. The most favorable results were obtained in early cases. These have been cured in five or six days. In the later cases the interval has been from six to eleven days. As to results viewed in relation to the situation of infection, septicemia originating in the throat or ear has resulted in 85.5 per cent recoveries. The cerebrospinal meningitis cases of otitic or traumatic origin have been followed by a smaller (64.55) percentage of recoveries.

#### Unusual Causes of Hemoptysis in Tuberculosis

At the February 7 meeting of the Société médicale des hôpitaux of Paris in a paper by Ameuille and his associates, four cases were reported of fatal hemoptysis in pulmonary tuberculosis due to aneurysms of the interstitial vessels, with resultant formation of one or more hematomas in the parenchyma of the lung surrounded by a shell-like capsule of fibrin. In all four cases the tuberculosis was of the ulceronodular type. In only one case was a denser irregular area on the roentgenogram, corresponding to the encapsulated hematoma, to be seen. Before searching for hematomas at necropsy, the authors advised placing the lung in solution of

formaldehyde for several days. Microscopic study revealed that the aneurysms were similar to those described by Rasmussen as occurring in the walls of cavities. In Ameuille's specimens as in Rasmussen's, there were afferent and efferent vessels with development of a sac filled with fibrin between these vessels. As to etiology, Ameuille is of the opinion that a segmentary necrosis of a tuberculous character takes place in a vessel in contact with a pulmonary lesion. This either results in the formation of an interstitial aneurysm with repeated small hemoptyses followed by a sudden fatal one or the latter takes place without any prior bleeding. Such pulmonary lesions have not yet been described, according to Ameuille.

### Diphtheria Mortality and the Insurance Physician

Diphtheria, on account of the severe form in which it appears in Germany, is of particular concern to the pediatrician. Dr Paschlau, staff member of a children's hospital, addressed the Berlin Pediatric Society on diphtheria. The question as to the efficacy of serum has been brought to the fore. It is to be remembered that in 1913 Professor Bingel of Brunswick, with a vast amount of data at his disposal was unable to distinguish appreciable difference between the effect of antidiphtheric serum and that of similarly injected plain horse serum (without antibodies). Since that time the skeptics have questioned the specific efficacy of antidiphtheric serum. After the war, diphtheria assumed a new character in many parts of Europe. Laryngeal diphtheria became less frequent, and since 1926 clinics in Berlin, Vienna, Dusseldorf and elsewhere have reported a great increase in cases of so-called toxic disorders of the nasopharynx which, despite abundant usage of serum have shown a mortality of 40 per cent or more. The amount of serum given has been increased, instead of from 200 to 500 antitoxic units per kilogram of body weight formerly employed as much as 100,000 units came to be given and this dosage has been increased even to 800,000 units. Results from these massive doses are disappointing. Paschlau brought out that in these toxic states the antidiphtheric serum in large doses as well as in combination with antistreptococcus serum, blood transfusions, arsphenamine and in the form of symbiosis serum has been proved powerless. Paschlau next traced the decline in the value of serotherapy since the armistice until now only on the first or second day of illness in toxic cases can even a modest degree of efficacy be anticipated. Few diphtheria patients, however, receive the serum at such an early stage. But if it became customary to administer serum at that early time the mortality from diphtheria would be greatly decreased. Statistics from two large children's hospitals in Berlin present an interesting contrast. At the Emperor and Empress Frederick Children's Hospital in only 37.2 per cent of all diphtheria cases and 34.4 per cent of the toxic type cases were injections of serum administered during the first two days of illness, but at the Berlin Municipal Orphanage and Foster Home the corresponding figure was 80 per cent. Accordingly the mortality in the Children's hospital averages 13.3 per cent, while that of the orphanage is only 1.96 per cent. So great a difference can hardly be due to a lack of order in the records of the more serious cases. The later term of serum administration at the Frederick Hospital is rather to be considered the responsible factor. The difference between the general mortality for Berlin (8.9 per cent) and that of the orphanage inmates (1.96 per cent) cannot be explained otherwise than by the greater efficacy of early administered antidiphtheric serum.

After so much research and with so many data the efficacy of the serum must be regarded as a fact. Of course great importance is attached to the time when the

serum is given, the propitious period lies so early in the course of the disease that the majority of patients never receive it until too late. According to Paschlau's experiments it is unnecessary to inject in excess of 1,000 antitoxic units daily per kilogram of body weight. Repeated injections are highly recommended so long as the local manifestations appear to be progressing. Apparently an antidiphtheria campaign to be successful must effect an improvement in urban public health centers for the working classes, especially with regard to the medical service. Paschlau emphasizes that so long as the insurance physician is compelled to treat from 100 to 150 patients daily, diagnoses of diphtheria in its earlier stages will continue to be difficult, besides, the insurance physician must still encounter much official red tape on account of the high cost of serum.

### Infection of School Children by a Tuberculous Teacher

In connection with the important topic of the infection of school children by a tuberculous teacher, Dr Marx, an official district physician, has furnished a valuable report. After the death from pulmonary tuberculosis of a Volksschule (elementary school) teacher, the children in all six grades of the school were given the Hamburger percutaneous tuberculin test. The results are given in the accompanying table.

#### Results of Hamburger Percutaneous Tuberculin Test

1 In the Deceased Teacher's Classroom			
Length of Time in Classroom	Number of Children	Positive	Negative
Six months	19	15	4
Two or more years	3	3	0
Five and one half years	32	22	10
Totals	54	40	14
2 In the Remaining Classrooms (Under Other Teachers)			
Total Number of Children	Positive	Negative	
184	36	148	

The difference thus speaks for itself. Roentgen examination of the group of forty children showed twenty-four in whom no focal shadows indicative of tuberculosis could be detected (slight lime deposits in the hilus were not regarded as pathologic) two inactive types, three suggestive types, and active tuberculosis eleven. Among the children from the other classes who showed positive reactions (thirty-six) there were found only two presenting active tuberculosis, two showed suggestive and eight inactive types of the disease, the remainder showed no shadows of foci.

Naturally in several cases the existence of independent familial sources of infection had to be taken into account. However, careful examination permitted of no doubt that the deceased teacher had been the sole source of infection for a great majority of those children who showed positive reactions. The data in this case may be regarded as a valuable contribution to our knowledge of what may be expected from an actively tuberculous teacher. The most expedient indication seems to be diagnostic group examinations of teachers, and these have already been undertaken in the affected district.

### Warning Against Public Recommendations of Medicaments

Time and again, for many years, responsible medical professional publications and organizations have sought means with which to curb the unauthorized (and hence naturally more favorable) recommendations and testimonials of medicaments by certain physicians. The propriety or efficacy of the many attempts heretofore made to deal with this problem is dubious enough (THE JOURNAL, Sept 9 1933, p 866). It is therefore interesting to know that the Berlin Aerztzammer (Chamber of Physicians) has issued a public notice, which is official for

physicians and which bears the superscription "Warning! In this notice all physicians are urgently requested to exercise the greatest possible reserve in the matter of public recommendations. The Aerzteammer must recently have observed that these unseemly recommendations, so obligingly given, were often being exploited by manufacturers in a manner contrary to the intention of the physician in question. If such recommendations are used for lay advertising then, according to decisions of the medical court of honor, the Aerzteammer must move that the physician be proceeded against as a violator of professional ethics. Only a short time ago the manufacturer of an aperient released "Confidential Information for Physicians." This man had obtained advice from various physicians which, according to the representation, was to be solely "for his own personal information" and which he subsequently caused to be printed. Hence the Aerzteammer urges that the practice of recommending medicaments be drastically curtailed or, better still, completely abandoned. This threatening admonition, it is hoped, may prove more effective than previous attempts to regulate this practice.

### Congenital Dislocation of the Hip Joint

The Erlangen anatomist Professor Pratje while studying the ossification of the pelvis, observed in several cases of congenital dislocation some remarkable variations. Changes occurring in the region of the ischia have indeed been recognized for quite a while. Development is clearly retarded at the time when the center of ossification first appears as well as in further course of growth. In cases of unilateral dislocation the center of the afflicted side is almost always a third smaller, namely, it possesses on an average a diameter smaller by 5 mm. In cases of bilateral dislocation there is a correspondence between the two sides. The joint socket in children presenting diseases of the hip joint shows a further flatness the upper portion remains steep and the rim of the socket is lacking. Thus at about the age of  $2\frac{1}{2}$  years the development corresponds to that of a normal infant aged 6 months. Following reduction of the dislocation, a normal socket can still be formed. In the second fusion of the bones, namely the fusion of the pubis and the upper ramus of the ischium, a similar retardation of development may be detected. While normally it requires from four to five years for the bones to become fused, in some of the cases observed it took seven years and in one case as long as twelve years. An open symphysis presents itself between the ends the length of which on the dislocated side is greater by many millimeters than the length on the normal side, in cases of bilateral dislocation the development of both sides is retarded. The center in the trochanter major appears much later on the diseased side and is always smaller than on the normal side, in bilateral disease this inferiority is equal. The normal development is temporarily retarded. Normal development is made possible by reduction. Whether it is a question of local retardation or of a retardation of the entire bodily development has not yet been finally decided. It is certain that these disorders are due to a hereditary embryonic defect, the power of which to transmit itself is rather slight. Pratje arrives at the following conception of the origin of congenital hip joint dislocation. Primarily it is a question of retardation of the normal course of development, not of a malformation due to arrest of development or to inherent deformity. As a result at the time when function should begin, both joint socket and cordyle are too flat and the socket rim is far too underdeveloped. Consequently the dislocation can be produced by a trauma or by normal functioning. If the dislocation is reduced early the normal development even if arrested resumes its course; if on the other hand the dislocation persists, functional phenomena of a wholly different kind may result, such as disorders of the vascular supply, these in turn lead to further severe disturbances of the

ossification and to pathologic states refractory to orthopedic and surgical intervention. The predisposition toward retarded development is inherited. The environment may strengthen or weaken the hereditary tendency. In this way the too flat socket originates. In undeveloped joints, function itself may lead to dislocation, in such cases hereditary predisposition and environment combine. Endogenous or exogenous causes act in unison, although the endogenous, the hereditary predisposition may be considered as the primary cause.

### Investigation of Nonhereditary Feeble-mindedness

A study of the first eighty cases recorded in a genealogical table by the department of genetics of the Erfurt (Thuringia) municipal health bureau shows fifty-one patients who have attended the school for backward children. It could be demonstrated that 76.47 per cent of this group were afflicted with hereditary disease, a hereditary taint could not be proved in six cases, an exogenous injury was a factor in two cases, and neither exogenous nor endogenous injuries could be detected in four cases. On the basis of these observations the relative incidence of hereditary and nonhereditary feeble-mindedness in early childhood was verified. The marked rarity of nonhereditary feeble-mindedness was likewise demonstrated. Since the first school years are the most propitious for such examinations and offer the best criteria, seventy-two pupils of the school for backward children were made to fill out a special questionnaire and examination blank. The gathering of accurate data was hampered, since occasionally the mother or father was unknown. Despite this handicap 236 brothers and sisters were established. Of this number alone 20.3 per cent attend school for backward children—in other words are mentally deficient. In all, 47.2 per cent of the seventy-two have tainted brothers and sisters, without including many borderline cases. Similarly, tainted parents, grandparents and so on are discovered in 52.8 per cent of the persons studied. This number is increased by about four when the entire tainted genealogy is considered. Therefore forty-two cases, or 58.33 per cent of the total, present histories of hereditary taint. By careful computation a maximum figure of sixty-four hereditary cases is arrived at against eight nonhereditary cases, a proportion of 88.8 per cent to 11.1 per cent.

### BELGIUM

(From Our Regular Correspondent)

March 15, 1936

### International Congress on Occupational Diseases

The seventh Congress on Occupational Accidents and Diseases was held recently at Brussels under the presidency of Mr. Gilbert. The assembly was divided into two sections, one of which presided over by Professor Langelez dealt with occupational medicine while the other, dealing with accidents was headed by Mr. François.

### HEAD INJURIES

Of 100 patients presenting cranial injuries, fifty survive. Thirty-five of the survivors present sequels and fifteen are pronounced cured. These cases are scarcely stabilized in less than twelve months subsequent to the accident. They then enter that third period which was the subject of the papers read. The term of one year fixed as a point of departure, is doubtless arbitrary, however it seems to constitute the most appropriate time from which to date this third period and study its evolution. Lippens stressed the difficulty of precise diagnosis and the necessity for thorough specialized examinations (ophthalmologic, cochleovestibular, neurologic, psychiatric, encephalographic, tensional and biologic). The measure of diastolic tension of the central retinal artery is an important but not pathognomonic factor in diagnosis. The pressure and modifica-

tions in the composition of the cerebrospinal fluid are not constants, yet they are of value. What appears to be the most reserved prognosis need not be the most unfavorable.

#### INJURIES OF THE HANDS

In addition to papers by Neuman and Bohler on the treatment of hand and finger injuries, Imbert submitted a study of lesions on the upper extremities in which he formulated two conclusions. 1 To the upper limbs, the fingers are everything, disturbances caused by an amputation of the fingers are almost as serious as an amputation of the arm. On the lower limbs, on the contrary, the seriousness of an amputation is increased the higher the level at which it takes place. Amputation of the toes is of minimal importance. 2 To the upper limbs a prosthesis is well nigh useless, to the lower limbs on the contrary, even the most simple prosthesis may determine the patient's ability to resume work. This difference is due to the fact that in the upper limbs it is mobility that counts, in the lower limbs, solidity. As mobility is the essential quality of the fingers, their fixation in any one position, whether flexed or extended is disastrous from a functional point of view. The thumb is the most useful, provided that at least one opponent muscle remains to it. This digit possesses a pathologic as well as a physiologic individuality. It stiffens less readily than the other digits and among them a simultaneously physiologic liaison, often a source of trouble, exists.

#### METHODS EMPLOYED IN COMBATING DUSTS

In evaluating any dust collecting apparatus the following factors must be taken into account: space occupied by the machine, efficiency, evacuation of the collected dust, temperature of the gas, expenditure of energy entailed, and the costs of installation and maintenance. There are three methods of eliminating dust and these correspond to three different types of apparatus: the dry, the wet and the electrical. Dust collectors of the 'dry' type may be based on the use of sacks, on gravity or on centrifugation. Wet or wet-screen apparatus may depend on a descending stream of oil or of water. The principle of the electrical apparatus is ionization.

#### GASES THAT ESCAPE FROM FIRE DAMP VEINS

Mr. Brey of Liege reviewed the gases found in Belgian mines. He discussed those which are encountered accidentally (sulfuretted hydrogen, carbon monoxide, carbon dioxide) and outlined briefly how they may be detected. The principal gas emitted is commonly known as fire damp which is composed of methane from 93 to 99 per cent, ethane less than 3 per cent, nitrogen, carbon dioxide, and hydrogen present only in traces if at all. For purposes of an anti-fire damp campaign, fire damp may be considered as pure methane. The most common device for the detection of fire damp is still the flaming safety lamp but to be of service it must be in competent hands. Other apparatus for prompt detection of fire damp are the Leon-Montluçon grisoumeter, the Spiralarm Naylor grisoumeter, the Zeiss interferometer, the Daloz apparatus and the McLukie apparatus.

#### DIAGNOSIS OF PAIN IN TRAUMATISM

De Laet stated that pain itself is a disabling sequel or it participates to some degree in the disability proper. Therefore it should be evaluated with the greatest possible accuracy. He reviewed the signs to be considered in making complete clinical examination of the patient: possible simulation, papillary dilatation, the pulse rate, the arterial pressure and the specific sign, fall of the urinary pH which he emphasized.

#### LESIONS DUE TO ELECTRICITY

Strassen of Liege said that 'electrical traumas' are of two varieties: (a) 'electrical shock' presenting the general phenomena of electrocution and (b) local lesions which have a characteristic appearance and must not be confused with ordinary burns caused by fire or chemicals. Any person suffering

from electrical shock should be considered in a state of apparent death. Treatment therefore should be similar to that employed in cases of submersion. As with drowned persons the body may be white or blue, but, regardless of the type of discoloration, basic treatment consists of artificial respiration practiced over a period of hours. The treatment of injuries due to electricity should be above all "conservative." Immediate amputation of carbonized members is seldom indicated. One should await until a precise natural demarcation between healthy and carbonized tissue has taken place. Mobilization of the members should be effected as early as possible in order to conserve the maximum tonicity of the undamaged tissues and to render the cicatricial tissues as flexible as possible.

#### Occupational Diseases in Belgium

The Belgian law providing compensation for damages due to occupational diseases dates from 1927. In the *Bruxelles médical* Dr. Langelez examines the results of this legislation. Up till 1934, only three diseases could be made the basis for such compensation. These were saturnism, hydrargyrisms and anthrax. Since 1934 the following diseases have been added to the original list: intoxication from phosphorus and its compounds, from arsenic and its compounds, from carbon disulfide, from benzene—its homologues, their amines and nitro derivatives, and from hydrocarbons of the fatty series and their chlorinated derivatives, pathologic disturbances due (1) to radium and other radioactive substances and (2) to roentgen rays, epitheliomas of the skin due to a handling of tar, pitch, bitumen, mineral oils, paraffin and all compounds or residues of these substances. Lead remains the most redoubtable of industrial poisons and saturnism the most truly classic of occupational diseases. Of a total of 436 cases in which indemnities were paid, 91 per cent have to do with saturnine intoxication. The two occupations in which the threat of saturnism looms largest are at present metal glazing and the manufacture of electrical accumulators. In seven years, twenty-seven cases of anthrax were recorded, the greatest number for any year was ten in 1929. Averages for the other years ranged from two to four cases. The most perilous industry from the standpoint of anthrax is the manufacture of gelatin: sixteen cases out of the twenty-seven were traceable to this activity. The manufacture of gelatin entails the utilization of bone fragments imported from foreign lands, particularly the Indies.

## Marriages

E. ROSS JENNEY, Los Angeles, to Miss Agnes Victoria Anderson of Oslo, Norway, in Santa Barbara, Calif., April 25.

WILLIAM DOBB ANTHONY to Miss Mary Maitland Parham, both of Waycross, Ga., in Waco, Texas, February 27.

CHARLES FRANCIS LEICH, Evansville, Ind., to Miss Carroll Mabel Duncan of Indianapolis, April 25.

SAMUEL MAYER DODER, Washington, D. C., to Miss Miriam Joyce Selker of Cleveland, April 13.

JAMES ANTHONY MCHUGH to Miss Georgia Mary Ingalls, both of Stockton, Calif., April 1.

IRVING J. WOLMAN, Philadelphia, to Miss Roslyn Carroll Stone of New York, April 12.

SEALS S. SPEER, Bay St. Louis, Miss., to Miss Alma Boyd of Converse La., March 7.

RICHARD K. FRAWLEY to Miss Alma Dustman Oakleaf, both of Titusville, Pa., April 25.

JOHN SUMTER CUNNINGHAM to Miss Phyllis Fenn, both of Hartford, Conn., recently.

CHARLES C. W. JUDD to Miss Mary Evelyn Webb, both of Baltimore, recently.

## Deaths

John Ridlon ♂ Newport, R I, well known orthopedic surgeon, died, April 27, at the Newport Hospital, aged 83. Dr Ridlon was born in Clarendon, Vt, Nov 24 1852. He received an A B degree in 1875 and an A M degree in 1878 from the University of Chicago, and his M D degree from the College of Physicians and Surgeons, Medical Department of Columbia College, New York in the same year. Dr Ridlon was an intern at St Luke's Hospital New York, from 1878 to 1880, and later attending orthopedic surgeon at the New York Orthopedic Dispensary and Hospital and instructor in orthopedic surgery at the New York University Medical School. He also had been a surgeon of the first orthopedic division of the outpatient department of Bellevue Hospital and assistant surgeon at the Vanderbilt Clinic, New York. From 1892 to 1898 he was professor of orthopedic surgery and head of the department at Northwestern University Medical School, Chicago and held a similar professorship in the Chicago Post-Graduate Medical School from 1892 to 1893, the Northwestern Woman's Medical School from 1898 to 1912 and Rush Medical College Chicago from 1909 to 1912. During the World War he served in the Medical Reserve Corps of the Army, retiring as a lieutenant colonel in the auxiliary reserve.

Dr Ridlon was secretary of the Section on Orthopedic Surgery of the American Medical Association from 1912 to 1913 and a member of the House of Delegates from 1914 to 1922. He was past president and secretary of the American Orthopedic Association, honorary member of the British Orthopedic Association a member of the Clinical Orthopedic Society and a fellow of the American College of Surgeons. He was an orthopedic surgeon at the Wesley and Presbyterian hospitals, Home for Destitute Crippled Children and the Home for Convalescent Children all in Chicago, and the Home for the Friendless at Evanston Ill. He was also orthopedic surgeon to the Mercy, Michael Reese and Evanston (Ill) hospitals and the Newport (R I) Hospital, later becoming consulting orthopedic surgeon. Dr Ridlon was a founder and a past president of the Home for Destitute Crippled Children, Chicago. He was awarded an honorary A M degree from Tufts College in 1899 and Sc D from the same college in 1926. He is said to have been the only living American orthopedic surgeon who knew Hugh Owen Thomas, and the first to adopt his methods. Dr Ridlon was a kindly, genial man with a keen sense of humor and was a source of inspiration to all the younger men fortunate enough to be associated with him.

Albert Harrison Brundage, Woodhaven, N Y University of the City of New York Medical Department 1885 member of the Medical Society of the State of New York fellow of the American College of Physicians, emeritus professor of toxicology and physiology, departments of medicine, dentistry and pharmacy, Marquette University Milwaukee, president of the New York State Board of Pharmacy in 1903, member of the Volunteer Medical Service Corps during the World War, inspector of the board of health from 1904 to 1921 toxicologist and later consulting toxicologist to the Bushwick Hospital author of A Manual of Toxicology published in thirteen editions, contributed articles on pharmacy and various subjects to technical and other journals, aged 74, died March 12, in the Central Islip (N Y) State Hospital of pneumonia.

Bramerd Hunt Whitbeck ♂ New York, Columbia University College of Physicians and Surgeons, New York 1903 professor of orthopedic surgery, University of Vermont College of Medicine, Burlington, member of the American Ortho-

pedic Association, fellow of the American College of Surgeons, served during the World War, aged 58 attending orthopedic surgeon to the Neponsit Beach Hospital for Children Rockaway Beach, consulting orthopedic surgeon to the Roosevelt Hospital, New York Memorial Hospital, Canandaigua, Vassar Brothers Hospital, Poughkeepsie, Benedictine Hospital, Kingston, St Luke's Hospital, Newburgh, and the Lawrence Hospital, Bronxville, where he died, February 29, of cerebral hemorrhage and arterial hypertension.

William Day Chapman ♂ Silvis, Ill, Washington University School of Medicine, St Louis 1908 past president and secretary, and for many years councilor of the Illinois State Medical Society, past president and secretary of the Rock Island County Medical Society, member of the House of Delegates of the American Medical Association, 1933 1935, served during the World War, aged 52, died, March 16, of facial erysipelas.

John Edward Hall Atkeisson, Chicago, Vanderbilt University School of Medicine, Nashville, Tenn, 1897 member of the Illinois State Medical Society, member of the Associated Anesthetists of the United States and Canada, aged 61, attending anesthetist to the Columbus Lutheran Memorial and St

Mary of Nazareth hospitals and the Grant Hospital where he died, March 1, of myocarditis coronary sclerosis uremia and gangrene of the right leg.

Isaac Walter Kite ♂ Surg, Lieut Commander U S Navy, retired Washington D C, Medical College of Virginia Richmond, 1885, entered the navy in 1886 and retired in 1910 for incapacity resulting from an incident of service, served during the Spanish-American and World wars, aged 74, died February 3, in the Naval Hospital of carcinoma of the prostate.

John Neilson Reik, Pelham Manor, N Y University of Maryland School of Medicine Baltimore, 1900, fellow of the American College of Surgeons served during the World War, formerly surgeon to the Baltimore Eye Ear and Throat Hospital, aged 63, died, February 24, in the Mount Vernon (N Y) Hospital of diabetes mellitus and cerebral thrombosis.

Seth Newland Thomas Auburn, N Y University of Buffalo School of Medicine 1900 member of the Medical Society of the State of New York and the Associated Anesthetists of the United States and Canada on the

staffs of the Auburn City Hospital and the Mercy Hospital, aged 62, died, March 4, of cerebral hemorrhage.

Edwin M Chauncey, Albion Mich, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1899, member of the Michigan State Medical Society, served during the World War, formerly member of the school board, aged 62 on the staff of the Sheldon Memorial Hospital where he died February 20 of pneumonia.

Eric Albert Crull, Fort Wayne, Ind, Marion-Sims College of Medicine St Louis, 1897, served during the World War at one time city health officer a founder, medical director and superintendent of the Irene Byron Sanatorium, secretary of the staff of the Lutheran Hospital, aged 59, died March 15, of cardiovascular disease.

Haroutoun Asadour Adrounie ♂ Hastings Mich University of Illinois College of Medicine Chicago, 1913, formerly secretary of the Barry County Medical Society county coroner, on the staff of the Pennock Hospital, aged 53, died February 28, in the University Hospital, Ann Arbor, of cirrhosis of the liver.

James Henry Colson ♂ Gainesville, Fla, College of Physicians and Surgeons, Baltimore, 1896, past president of the Alachua County Medical Society, formerly member of the state legislature, superintendent of the Florida Farm Colony, aged 69, died suddenly, March 5 of organic heart disease.

JOHN RIDLON M D 1852-1936

Frank B Thompson ⊕ La Fayette, Ind , Starling Medical College, Columbus, 1882, fellow of the American College of Surgeons, chief of the surgical staff of the La Fayette Home Hospital and surgical director of St Elizabeth's Hospital, aged 79, died, February 1, of chronic myocarditis and arteriosclerosis

John Henry Mountain, Middletown, Conn , Jefferson Medical College of Philadelphia, 1896, member of the Connecticut State Medical Society, health officer of Middletown, formerly state senator, on the staff of the Middlesex Hospital, aged 66, died, March 6, in St Raphael's Hospital, New Haven

Harold Ball Disbrow ⊕ Lakewood, N J , Johns Hopkins University School of Medicine, Baltimore, 1916, fellow of the American College of Surgeons, served during the World War for many years on the staff of the Paul Kimball Hospital, aged 46, died, March 21, of cerebral hemorrhage

Omar J East, Reed City, Mich , Detroit College of Medicine, 1899, member of the Michigan State Medical Society, health officer of Reed City, on the staff of the Reed City Hospital, aged 68, died, March 10, in the Blodgett Memorial Hospital, Grand Rapids, of meningitis

### ELORDA CREAMS

#### Another "Alice in Wonderland" Cosmetic

Because of the lack of any national control of claims made for cosmetics, the advertising agencies that prepare "copy" for their clients in the cosmetic field permit their copywriters' imagination to run riot Each year sees certain cosmetic advertisements that would appear to be the apotheosis of fantastic foolishness

We have become used to, and hardened against, the appealing claims made for face creams having as a base hormones from armadillos, turtles or ring-tailed monkeys Creams that make one thin and creams that make one fat Creams that are the result of years of "scientific research" by unnamed scientific researchers, creams that banish wrinkles, cares, worries and perhaps next the mortgage on the old homestead, creams that coax, if not the skin, at least a fancy price from milady's purse But the end is not yet! A large display advertisement appearing in a magazine devoted to women's interests asserts that there is now on the market "The Most Astonishing Developments in Beauty Care Ever Offered to American Women" It appears from the advertisement that most American women past twenty suffer from chronic dryness of the skin and premature wrinkles, but, explains the advertiser hope fully, while the two conditions usually go hand in hand, "the removal of one would mean the removal of the other" But how can they be removed

The answer lies in two amazing new creams Elorda Creams that are perfectly suited to performing this duty Elorda Creams see to it that your skin gets plenty of stimulation (to coax the glands into producing more softening sebaceous oil) and plenty of external lubrication

Should any question arise in the minds of those who can read an advertisement of this sort without a feeling of nausea as to just how the effects are going to be produced, the advertiser goes on to state

And the almost incredible reason for the effectiveness of Elorda Creams is that *they are made with gold!*

"Almost incredible" would appear to be the most conservative statement in the advertisement To any rational being, it would appear quite incredible Reading further, one is given to understand—if he knows enough—that "the gold in Elorda Creams is in a special scientific form—soft, smooth, pink in color" In other words, presumably colloidal gold is used and the modus operandi is still further elaborated thus

Each microscopic drop of this gold possesses a negative electrical charge On the other hand dead cuticle grime and other foreign matter in the skin has a positive charge As ever when positive meets negative they attract with the result that the gold carries the captured grime to the surface where it can easily be removed

Nor is this all, for the Brownian movement common to colloidal solutions is called into action

And because these atoms of liquid gold are in a state of constant agitation they act on the skin as massaging and stimulating agents Through their stimulating action normal circulation is restored and the skin is completely revitalized

In view of the fact that advertisements of this sort cost a great deal of money and that business concerns, even those which sell cosmetics, will not pay out money unless there is a large return to be expected, the thoughtful may well wonder whether science has not given the human race an undeserved compliment in classifying man as *Homo sapiens* It is doubtless true that any reference to gold will immediately stimulate the imagination and the greater the ignorance of chemistry, pharmacology and dermatology the greater the amount of stimulation It would be a gross understatement to say that there is not the remotest scientific basis for the incorporation of colloidal gold into face creams and it certainly would be no exaggeration to describe the advertisement of Elorda Creams as a particularly blatant example of cosmetic quackery

## Correspondence

### SEDIMENTATION RATE IN JUVENILE RHEUMATISM

*To the Editor*—In an editorial on the sedimentation rate in juvenile rheumatism (THE JOURNAL, March 14, p 925) the effect of anemia on this test is mentioned. It is also stated that the method of bringing the red cell count to normal before performing the test is too cumbersome for routine use. Payne and Schlesinger in their recent paper, which seems to be the basis of this editorial, say that there is an absence of any accurate method of making corrections for anemia.

It therefore seems important to call attention to the fact that a relatively easy and satisfactory method of correcting the sedimentation rate for the anemia factor was described in 1930 by Rourke and Ernstene (*J Clin Investigation* 8:545 [June] 1930). This method involves the simple procedure of centrifugating the tube containing the blood so that the hematocrit may be determined. From a chart constructed experimentally by these investigators the sedimentation rate which the blood sample would have if it had an arbitrary normal hematocrit of 45 may be determined.

Experience with the sedimentation rate used as a routine test during the past four years at the House of the Good Samaritan has decidedly shown the importance of correcting for changes in the volume per cent of the red blood cells. Relatively slight degrees of anemia may considerably accelerate the sedimentation rate, and a slight degree of anemia has been found to be quite prevalent in patients with rheumatic fever. Thus, many apparently abnormal rates fall well within the normal zone after the hematocrit has been determined and a correction made.

Any method which fails to correct for this anemia factor is subject to grave errors and therefore is not to be relied on.

The method of evaluating the effect of anemia by the use of a curve such as that described by Payne and Schlesinger does not make an actual correction and is therefore less reliable than the method of Rourke and Ernstene. It also involves the additional procedure of making a red blood cell count that is less accurate and more difficult to determine than the hematocrit. Furthermore, unless the red blood cell count is made on the same sample of blood as the sedimentation rate there is still greater chance for error, since the relative blood cell volume is not constant.

BENEDICT F. MASSFELL, M.D., Boston

### GARGLES

*To the Editor*—I should like to say a few words about the gargle, which has of late come into disrepute particularly since many investigators have discredited it.

Snow and Stern (THE JOURNAL, Sept 15 1934 p 831) conservatively suggest that the gargle does not reach the interior furrows. Harse (*Klin Wchenschr* 14:1244 [Aug 31] 1935) using the same technique (the subject gargles with a thin barium sulfate suspension before the roentgenogram is made) concluded that the gargle reaches the palatine arch and the upper tonsillar pole but does not reach the tonsils themselves or the posterior pharyngeal wall. It would be well if conclusions such as the latter could be confined to their own locality. Unfortunately reports emanating from Germany have a way of achieving international prominence and our own 1935 Handbook of General Therapeutics has embodied Harse's article into a chapter further indicting the gargle.

It is not my purpose to extol the gargle so much as to criticize the ultrascientific methods employed in denouncing it. It does seem more practical to look directly into the throat

than to take roentgenograms of the contrast medium. If any one will take the trouble of examining the throat of a subject who has just gargled with a thick suspension of bismuth subcarbonate, he will find that every part of the mouth and throat, including the tonsils, posterior pharynx and even the piriform recess, is coated. With the commotion that occurs during gargling, can anything less be expected?

JULIUS KAUNITZ, M.D., New York

### DISLOCATION OF THE KNEE JOINT

*To the Editor*—In THE JOURNAL, April 11, page 1252 the authors state that "the records of many large hospitals fail to show a single case of a complete dislocation of the knee." This statement is not in accord with the literature. I reported in THE JOURNAL, Oct 5, 1935, p 1111, a case of complete dislocation of the knee with photographs of the x-ray films before and after reduction. It is of interest that, in comparing the roentgenogram of my case with that of the later case, one is a mirror image of the other, for in my report the right knee was involved while in the latter the left knee was involved.

I am pleased to note that Conwell and Alldredge, the authors of the later case, also obtained excellent results, as did I in my case, by using the method of reduction and postreduction care as I described in my original article.

A. M. FICHMAN, M.D., Fort Wayne, Ind

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

### MUSCLE CRAMPS

*To the Editor*—A white man, aged 36, American, has been troubled with muscular cramps in the extensor muscles of the left thigh in the toes in the fingers and in the lower chest region. He first noticed them in 1917. Since that time they have not seemed to be getting any more severe but the cramp in his left thigh is extremely severe whenever it does occur. He has never had any trouble with his right thigh. He experiences these cramps in his toes every night immediately following the removal of his shoes at bedtime but never has them at any other time. The cramps in his fingers usually come on at various times during the day and may be present in one or several fingers at the same time. He is a painter and repair man for high water towers and he is greatly alarmed for fear that he might sometime have a disastrous fall because of these muscular cramps. His work is not steady and he states that he is troubled just as much when he is not working as he is when he is working hard. He believes that occupation does not seem to influence him in respect to his muscular cramps. He has been told that some one was cured by one hypodermic treatment. If you know of any such satisfactory treatment I should like to be informed.

M.D. Nebraska

ANSWER—It may be a fair assumption that the patient does not have any detectable disease to account for muscle cramps over a period of twenty years; nevertheless, an attempt should be made to determine whether the muscle cramps are a manifestation of tetany. It seems quite obvious from the history that uremia, hyperventilation, and obstructive lesions of the proximal gastro-intestinal tract are absent. The correspondent should determine whether or not the Chvostek and Trousseau signs are negative. The blood calcium should be determined because of the slight possibility of hypoparathyroidism due to diminished parathyroid function. Since the patient is a painter, the possibility of chronic lead intoxication should be considered. If these investigations disclose nothing abnormal the cramps may be considered of the common variety which do not result from recognized disease. Hunter (*Internat Clin* 4:109 [Dec] 1932) gives an excellent description. Half awake in the morning one lazily stretches out and is suddenly seized in one calf with a very painful cramp which lasts about a minute during which the tendo achillis is powerfully contracted drawing the fore part of the foot downward. The mechanism of these cramps has been presented by Marx (*California & West Med* 38:96 [Feb] 1933). Muscle cramps are usually brought on by sudden exaggerated or wrongly directed impulses when a

muscle action does not meet the anticipated amount of resistance or is not checked by the controlling antagonistic muscles, as is normally the case. After producing a maximum contraction the superfluous amount of muscle energy liberated by the disproportionate impulse is converted into a muscular spasm."

Muscle cramps occurring during sleep appear to arise in the same manner as do those which follow stretching except that the primary muscle contraction is an involuntary or sleep movement in the former instance and voluntary in the latter instance.

The treatment during the episode is the forced manual extension of the muscle involved by the cramp. If, for example, the muscles of the calf are involved, the foot should be forcibly dorsiflexed. Prevention of the episodes is usually simple avoidance of unopposed muscular contraction, as during stretching or swimming in cold water by those having a predisposition to cramps. Individuals who suffer during the sleeping hours should be fitted with a special shoe or boot to prevent involuntary muscle contraction. In many instances such muscle cramps are relieved by the administration of dilute hydrochloric acid three times daily or one of the calcium salts such as calcium gluconate, in amounts of 4 Gm three times daily, or one of the acid bearing salts, such as ammonium chloride, which can be given in amounts as large as 3 Gm daily three out of each five days. A smaller amount of ammonium chloride will doubtless suffice.

#### DEMENTIA PARALYTICA

To the Editor—A man about 40 years of age whose condition has been diagnosed as syphilis of the central nervous system with incipient dementia paralytica has been under my care for the past six months. This diagnosis is based on both neurologic and serologic examinations. He has received hyperthermy with intravenous typhoid. He also has had Potassium iodide 10 minims (0.6 cc) for three months three times daily.

Tryparsamide 0.3 Gm for twenty doses

Bismuth in oil 0.025 Gm for twenty doses

Colloidal mercury 2 grains (0.13 Gm) for twenty doses

At present the blood Wassermann reaction is 4 plus. The neurologic condition has shown no definite changes either for improvement or for progression. Mentally however the patient is more cheerful. Because he strenuously objects to a spinal puncture until his blood is negative the cerebrospinal fluid has not been reexamined. I will appreciate any criticism you may make as to my method of treatment to date and what help you can give me as to the future treatment of this patient. Kindly omit name.

M D West Virginia

ANSWER—The question does not state what psychiatric clinical manifestations the patient shows. Not all parietic patients are benefited even by hyperpyrexia for the percentage of remissions is only from 30 to 40 per cent. One has the impression that the fever was not elevated sufficiently in the treatment given this patient.

It is suggested that a course of twelve bouts of hyperpyrexia, reaching 104 to 105 F for at least four hours, be given. The interim treatment of heavy metals and tryparsamide is correct. It is suggested instead of typhoid vaccine that malaria be given.

#### NEVUS VASCULOSUS

To the Editor—I have under my care a boy aged 8 months a perfectly normal and developed infant who has a congenital 'nevus vasculosus' or angioma on the right cheek. The growth begins at the angle of the lip and is approximately 3 by 4 cm in size of port wine color and somewhat elevated the surface being studded with small nodules. He is now under the care of a competent radium specialist who has given three treatments within a period of five months. The growth has not diminished in size but shows some blanching. The parents have been told that the radium emanations will store up in the baby's system and cause trouble in later years. Is there any clinical data to support this theory? What in your opinion is the most satisfactory treatment of the condition from a cosmetic standpoint? Please omit name and address.

M D New York

ANSWER—The radium treatment carried out in this case as described is probably the best thing to do to blanch the redness. For the elevated part of the lesion it would probably be desirable to freeze with carbon dioxide. After radium has been used, because of the obliteration of blood vessels that it causes the skin is more sensitive to freezing with carbon dioxide and the treatment should be made about half as long as on untreated skin say from five to seven seconds instead of from ten to fifteen. In the application of radium to the surface as is done in this case there is not the slightest danger of systemic effects from the storing up of emanations in the tissues. The only thing to guard against is overdoing the effect on the skin.

Radium or x-rays on the one hand or carbon dioxide on the other give the best cosmetic results. Carbon dioxide is advantageous in elevated lesions. In flat lesions they cause some shrinking of the contour of the surface. Neither is entirely satisfactory in cosmetic results in port wine marks.

#### ANOREXIA IN A CHILD

To the Editor—Dr. Boyd's article on growth brings to mind one of my most puzzling cases. A girl now nearly 3 years of age has had no appetite since birth. Always she has had to be fed and even then will hold food in her mouth for as long as half an hour before either swallowing or spitting it out. Almost daily her mother must punish her to get her to swallow. She likes to play with candy but makes no attempt to eat it. At birth she had a long head and a cleft palate the latter being blamed by the surgeons and pediatricians who have seen her for her aversion to eating. An excellent repair of the cleft palate did not improve the condition at all. In addition to this or because of it there has been no growth of the long bones particularly the humerus and femur. Otherwise she has seemed to develop normally. She is not thin or anemic. She is contented and quiet and she plays and talks normally. Her mentality is apparently normal for her age. From this description can the type of this abnormal growth be diagnosed and is any treatment possible?

HAROLD C MILLER M D Eglen W Va

ANSWER—It seems possible that there are two separate conditions here, though a single explanation can be given. The commonest cause of refusal of food or of holding it in the mouth for long periods before swallowing it or spitting it out does not lie in the child but in the handling of the child. Most such children respond quickly to change of environment, particularly if they are placed among other children in a hospital or a child-caring institute. It is to be emphasized too that the quantity of food a dwarf requires depends on size, not age.

On the other hand there is certainly here an anomaly of the palate and of the factor that causes growth of the long bones. Symmetrical retardation of growth with prolonged refusal of solid food occurs in some cases of the symptom complex known as renal rickets or dwarfism. There is then usually a greater or less degree of polyuria and polydipsia. The urine contains a trace of albumin, sometimes a few pus cells, sometimes granular casts. There may or may not be rachitic changes in the bones. Some of these cases are undoubtedly due to pituitary malfunction and probably would respond to the growth promoting factor were it obtainable. Improved appetite has been reported following the administration of thyroid but has been only temporary. Apert recommends a milk and vegetable diet with small doses of sodium citrate. Such treatment will depend on the finding of loss of kidney function and of change in mineral metabolism.

Finally the data supplied suggest an abnormal growth differential of the type of achondroplasia. A definite diagnosis cannot be made without more data than have been supplied.

#### HYDATIDIFORM MOLE WITH PERSISTENT BLEEDING

To the Editor—A married woman aged 23 has always been in perfect health except for an allergic sinusitis and an irregular menstruation. She began menstruating at the age of 13 years. Menstruation was always irregular sometimes with intervals of four or five months but it was normal when it did come. The patient became pregnant in the fall of 1932. No menstruation occurred for four months and then there was a miscarriage. No fetus was found just a few pieces of a rather darkish spongy placenta. These pieces were not closely observed. The patient became pregnant again in the fall of 1934. All signs and symptoms of developing pregnancy were observed. No flow or discharge took place until August 1935 then pain and flowing occurred. She was curetted with a dull curet and the gloved finger. Again no fetus was found. Peculiar looking pieces of afterbirth were submitted to a pathologist who pronounced the condition a benign hydatid mole. After eight weeks of uneventful recovery an Aschheim-Zondek urine test for pregnancy was done and it was negative. No menstruation flow or discharge after the last miscarriage occurred for a little over three months and then there was a rather profuse hemorrhage which gradually subsided over a period of ten days. She is still in bed although not flowing. What shall I do?

M D California

ANSWER—Every woman who has expelled a hydatidiform mole or has had one removed should have an Aschheim-Zondek or a Friedman test of the urine performed once a month for the first six months after the mole has been removed. For the following six months the biologic tests should be performed every two months and during the second year three more tests should be made. Although a chorionepithelioma may occur many years after a hydatid mole has been expelled it is generally safe to discontinue the biologic tests after two years. If however irregular bleeding occurs one of these urine tests should be performed without delay regardless of whether such bleeding occurs a few weeks or a few years after the removal of a hydatidiform mole. A positive Aschheim-Zondek or Friedman test weeks or months after the expulsion of a mole is indicative of a malignant change unless a new pregnancy has started. Hence whenever a positive urine test is obtained, one should first be certain to rule out a new pregnancy. This may not be easy at first. Usually in the presence of a new pregnancy there is an amenorrhea whereas when a chorionepithelioma

homa is present there is irregular and often profuse bleeding. Since an abortion may occur early in a new pregnancy, all tissue expelled from the vagina should be carefully examined microscopically. If a positive Aschheim-Zondek or Friedman test is obtained after the expulsion of a hydatidiform mole, especially if there has been irregular bleeding, a curettage should be performed and the scrapings should be examined by an experienced pathologist. In addition, evidence of metastases of a chorionepithelioma should be sought in the vagina and in the lungs. A roentgenogram will help to determine the latter. In the present case another Aschheim-Zondek test should be made and a curettage performed without delay.

#### TRICHOMONAS INFECTION IN MALE

*To the Editor*—I am treating a man who has a urethritis and also a prostatitis due to *Trichomonas*. A number of recent examinations made of the urine by a competent technician were positive and I am confident that there is no doubt as to the diagnosis. There is a stricture about the middle of the urethra which I attribute to this infestation owing to the fact that the patient gives a history of never having had any venereal infection. Also the prostate is enlarged and boggy and very tender. About one year ago the patient's wife had a severe and protracted vaginitis which was due to *Trichomonas* infestation but she has not shown any evidence of a return of the trouble. Please outline a treatment that I may use in this man's case that will enable me to relieve him of his trouble. Kindly omit name and address. MD West Virginia

**ANSWER**—Infection of the urethra in the male and of the prostate with *Trichomonas* is comparatively infrequent. The presence of *Trichomonas* in the urine is particularly difficult to establish. Although a number of cases have been reported in which *Trichomonas* was found in the secretion from the urethra and from the prostate it is not at all common. Stricture of the male urethra as a result of *Trichomonas* is even more unusual, since as a rule the infection is of a superficial type.

The treatment of infections of the urethra and prostate with *Trichomonas* in the male should be much the same as with the ordinary type of infection, namely, prostatic massage with increasing vigor, two or three times a week and Janet irrigations of the urethra. For the latter purpose solutions of potassium permanganate, 1:8,000, and acetic acid, 1:3,000, might be used on alternate days. Following massage, instillations in the deep urethra of mild protein silver 10 per cent or weak solutions of silver nitrate may be of benefit. Although it has no specific action, potassium iodide internally might also be given. Needless to say intercourse should be interrupted during the period of infection of either husband or wife.

#### STAMMERING BLINKING AND LEFT HANDEDNESS

*To the Editor*—A boy aged 6 years of normal mental and physical condition has suffered from stammering for the past two years. His natural tendency is toward left handedness but he has been trained by his parents to use his right hand as much as possible. For the past year he has been developing a marked blinking of both eyes. Do these features point to a symptom complex of a neurotic type? Do they have any relationship to each other? Please omit name and town.

MD New York

**ANSWER**—Orton has found that many left handed individuals develop speech disturbances when they are forced to write with their right hands. He has developed an intricate theory of cerebral dominance which is not particularly intriguing but the empirical observations have been confirmed.

It is suggested that the first step be to allow the boy to write as he wishes, with his left hand. The blinking of his eyes is a neurotic symptom and probably has no relation to his stammering if the latter be due to the foregoing mechanism. Both the stammering and the blinking may be symptoms of a neurosis and if changing his writing to the right hand has no effect on stammering, the whole syndrome should be treated as due to a neurosis.

#### INDUSTRIAL HAZARD IN POLISHING COMPACTS

*To the Editor*—I should appreciate any information you have available as to the substances used in polishing the chrome plate and enamel on cosmetics or cosmetic containers. Is the inhalation of the dust arising from this process coming from the polishing agents chrome or enamel responsible for any constitutional disturbances? Please omit name.

MD New York

**ANSWER**—The thickness of chrome plating on metal cosmetics or metal cosmetic containers is so slight (about one-millionth inch) that polishing or buffing is ordinarily objectionable. Particularly is this true of the cheaper varieties of compact. Chrome plating should yield so bright a finish as to make polishing or buffing unnecessary. When carried out it

is customary to use levigated white aluminum oxide. This is mixed with stearic acid to give body to the compound. At times chrome plated objects are polished with a mixture of chromium oxide and stearic acid. Prior to chrome plating of compacts and most other objects, a preplating with nickel is carried out. This nickel plating calls for polishing, which commonly is done with unslaked lime again mixed with stearic acid and possibly with Japanese wax. The highly polished surface of enamel or porcelain compacts is obtained not by wheel polishing but by fire polishing in a furnace. None of the substances used as polishes, or the dusts from the metal surfaces or from the polishing wheels, will cause any characteristic systemic occupational disease. When green chrome oxide is employed "chrome holes" readily are produced. In nickel polishing the calcium oxide may lead to irritation of the skin, eyes or throat. All dusts are harmful to some extent, so that in this work respiratory inflammation is a fair expectancy. Increased rates of pneumonia and tuberculosis long have been associated with the trade of polishing and buffing.

#### PERSISTENCE OF QUININE EFFECT

*To the Editor*—A recent obstetric case raised a question in my mind as to whether a prolonged delay of quinine activity was possible. A patient of mine scheduled for delivery Dec. 22, 1934 was still on deck by December 29. Since she was growing tremendous in proportion to the expected growth it was felt that induction of labor was indicated. Quinine sulfate 2 grains (0.13 Gm.) was given her every half hour following a castor oil cleansing. No immediate contractions were established and as the days went by an occasional spasm was felt but nothing to speak of. January 11 exactly two weeks after the attempted induction the patient went into violent labor and labored for more than twelve hours with the pains only two or three minutes apart. Little progress was made however as the head had attained unusual proportions by this time and the mother had a small pelvic outlet to begin with. The baby was finally delivered with Kielland's traction forceps. The question that has for a long time puzzled me and that I wish clarified is this: Can it be possible that after two weeks delay the quinine induction finally began to work? From my observations in previous cases I was well acquainted with the tumultuous and violent labors precipitated by this method and I am certain that this case was one of that type.

M F STEIN MD Chicago

**ANSWER**—Quinine does not stay in the system as long as two weeks, and one could hardly visualize a quinine "absent treatment."

#### DIFFERENTIAL DIAGNOSIS OF OBESITY

*To the Editor*—In a child who has obesity either of the hypothyroid or the hypopituitary type what tests can I use to determine which is the type? Are there any reliable tests to differ between the anterior and posterior lobe pituitary type? I should like an early reply as I wish to start treatment. Please omit name.

MD New York

**ANSWER**—Except for determination of the basal metabolic rate in hyperthyroidism there are no established laboratory tests to distinguish between the alleged types of obesity to which reference is made. There have been many experimental approaches to this problem most of which depend on testing the blood or urine for one of the hormones secreted by the anterior lobe of the pituitary gland. Until more certain and practical laboratory criteria are established the differentiation will have to remain on a dubious clinical basis.

#### AMYOTROPHIC LATERAL SCLEROSIS

*To the Editor*—I would appreciate knowing the latest form of treatment for amyotrophic lateral sclerosis.

CARL B. YOUNG MD Houston Texas

*To the Editor*—Please designate the latest therapeutic measures employed for amyotrophic lateral sclerosis. What are the etiologic factors known today in this disease? Please omit name and address.

MD Florida

**ANSWER**—Amyotrophic lateral sclerosis is probably a degenerative disease which attacks the anterior horn cells particularly of the cervical enlargement thus giving rise to atrophies in the upper extremities. It also involves the lateral tracts, causing spasticity and exaggerated reflexes in the lower extremities.

There has been no discovery of known value in the treatment of true amyotrophic lateral sclerosis. Strichnine in full doses may help to strengthen the weak muscles but it also tends to aggravate the spasticity. Aminocaproic acid which has some times proved helpful in muscular dystrophy has been disappointing but may be worthy of trial. About 15 Gm of this substance may be given two or three times a day.

There are no specific etiologic factors known for this disease. It must be remembered however that the symptom complex of amyotrophic lateral sclerosis may be caused by syphilis.

## BACTERIOSTATIC ASTRINGENT PREPARATION

To the Editor—For some time I have been prescribing the following

R Magnesium sulfate	3 ounces
Boric acid	2 ounces
Aluminum ammonium sulfate	1 ounce
Menthol	35 grains
Mix	

This I have prescribed for a vaginal douche one or two teaspoonfuls to a quart of water. I have often prescribed it for a wet or dry dressing. I have prescribed it for tired aching feet. Please advise if the formula has any antiseptic qualities as I have obtained some wonderful results from it. What is in it that gives such good results? M D Georgia

ANSWER—The combination is bacteriostatic, though not disinfectant. Its efficiency is chiefly due to the astringency of the alum accentuated by the production of exosmosis due to hypertonic magnesium sulfate solution. The menthol has, no doubt, a good deal to do with the immediate grateful cooling sensation resulting from this application.

## SAFE ANALGESICS

To the Editor—Is there a safe anodyne other than narcotic? I know that unpleasant sequelae have occurred after some of the barbiturates. Would you consider it wise to give these frequently for relief of pain?

M D Pennsylvania

ANSWER—Cure of the cause of pain rather than frequent administration of any analgesic is the goal of therapy. A constant pain due to an incurable condition should be relieved by section or destruction (e g, by alcohol) of the sensory nerve involved.

Acetylsalicylic acid is probably the safest and most generally useful analgesic. The action is enhanced by combination with a barbiturate, such as phenobarbital. If it produces excessive sweating, it may be combined with extract of hyoscyamus, as in this prescription:

R Extract of hyoscyamus	0.15 Gm
Phenobarbital	0.50 Gm
Acetylsalicylic acid	5.00 Gm
M Div into fifteen capsules	
Label One every two to four hours as required	

## DEXTROSE SOLUTION INTRAVENOUSLY

To the Editor—In the intravenous injection of dextrose what is the best strength to use? In a country practice without laboratory facilities or distilled water would it be proper to administer the stronger solutions as supplied by pharmaceutical firms, say 25 per cent and 50 per cent? Please omit name.

M D Pennsylvania

ANSWER—A 5 per cent solution of dextrose is the best strength to use, as it is approximately isotonic with the blood. If the patient is also in need of sodium chloride administration it is best to employ a solution of 2.5 per cent dextrose and 0.425 per cent sodium chloride. Such solutions are readily obtainable on the market in convenient containers suitable for administration in domestic practice. The stronger solutions should not be used unless osmotic effects such as those due to the hypertonicity of the solution are aimed at. For description see New and Nonofficial Remedies.

## ERGOTAMINE AND SCLERODERMA

To the Editor—Can you tell me whether ergotamine has been employed to any extent in the treatment of scleroderma and whether any case reports have been published? I should also like to obtain information concerning the pharmacology of this drug and its use in other conditions such as acrodynia. Please omit name.

M D Ohio

ANSWER—No case reports on the use of ergotamine in scleroderma seem available. Ergotamine is an active principle of ergot capable of exerting the effects characteristic of the drug including the peripheral vascular effects which may, among others, resemble those of acrodynia. It seems unlikely that ergotamine would be used in the therapy of this condition.

## LIMBER NECK AND POLIOMYELITIS

To the Editor—Your reply to a query regarding relationship of limber neck of fowls and poliomyelitis in the March 21 issue of THE JOURNAL is read with considerable interest. From personal study of forms of paralysis in fowls and swine I am very sure your answer is accurate. I do however premise to call your attention to the fact that poultry pathologists do not recognize the condition popularly termed limber neck as an entity. Rather it is a symptom manifested commonly in such conditions as emaciation due to intestinal worm and tuberculo and in fowl typhoid, leucosis, range paralysis and perhaps other diseases in addition to botulism.

## Book Notices

**Otosclerosis.** By Louis K. Guggenheim, M.D., F.A.C.S., Assistant Professor of Clinical Otolaryngology, Washington University School of Medicine. Cloth. Price \$6. Pp. 212 with 127 illustrations. St. Louis: Louis K. Guggenheim, 1935.

The subject of otosclerosis continues to intrigue the interest of the otologist and of others as well who are concerned with the problems of the deafened. It is a disease particularly of the young and those in early adult life. The female at puberty and in the child bearing years is one common type of victim whose plight arouses the sympathy of those about her. Though it seldom leads to absolute deafness there is frequently enough impairment to interfere seriously with the happiness of the affected individual in social and industrial contacts. It is by no means a rare disease. Shambaugh and his associates in a study of deafness in members of the League for the Hard of Hearing estimate that 70 per cent suffered from otosclerosis with primary stapes fixation. The American Otological Society has been a leading force in this country in a campaign to solve the problems of this affliction. It has collected funds established a permanent records bureau, and financially aided investigations at various universities. As to etiology there is at present no agreement. One recent textbook mentions no less than ten different theories and while some of these are not mutually exclusive they vary widely enough. For instance rickets is thought by some to be a cause. Still others, while not admitting the rickets theory, think that it is due to a disturbance of calcium metabolism. Others feel that it is closely akin to osteitis fibrosa. Still others that it is closely related to Paget's disease. Wittmack is a prominent exponent of the notion that it is due to labyrinthine congestion and there are those who feel that the real cause is a fundamental underlying disturbance of the glands of internal secretion. It has been thought for a long time that, whatever the cause, a hereditary factor is present.

The author has taken for his thesis the idea that otosclerosis is hereditary and is a regression. His studies lead him to believe that the changes in otosclerosis manifest at puberty or later do not arise at this time but are due to changes in anlage presented early in the embryologic history of the man. He believes furthermore that the condition is a throwback so to speak, to ancestors of the human race far down the line of vertebral descent. He has devoted much time and thought to his thesis. Starting far back he undertakes a phylogenetic study of the labyrinth, beginning with the Cyclostomata. He then discusses the development of the human aural capsule from the earliest embryologic times. He has been fortunate enough to obtain a six weeks embryo the mother of which suffered from a classic form of otosclerosis. The sections obtained from the embryo are described in detail and present conditions that are highly suggestive. It is the author's belief that otosclerosis is

perhaps due to a throwback to ancestral forms in which the labyrinth contains no windows, oval or round. In those human beings containing certain genes there is an attempt on the part of nature to reproduce the primitive labyrinthine type. His argument is bolstered by the fact that in most instances of otosclerosis the chief areas of activity seem to be in the region of the labyrinth windows, particularly the oval one, in which rests the foot plate of the stapes. While few will admit that the author has proved his point beyond all shadow of a doubt, it may be said that an ingenious and daring attempt at explanation has been made. The book gives evidence of much thought and reading. The arguments are well marshaled. The prevailing theories are presented with an interesting appraisal of each. The reproductions of photomicrographs are unusually well done and those interested in otosclerosis will derive much information, pleasure and stimulation from a reading of this work.

**The Source of Infection in Puerperal Fever Due to Hemolytic Streptococci.** By Dora C. Colebrook. Medical Research Council Special Report Series No. 205. Paper. Price 1s 6d 1p 99. London: His Majesty's Stationery Office, 1935.

Puerperal sepsis remains a principal cause of maternal mortality despite the present general knowledge concerning antiseptics and asepsis and the use of improved technical methods. Although extensive epidemics of puerperal fever now occur infrequently, the sources and types of infection in sporadic cases are of deep interest and require careful study.

The hemolytic streptococcus has long been considered the chief etiologic agent of puerperal sepsis, the incidence varying from 25 to 90 per cent. Only in the past few years have different groups and subgroups of hemolytic cocci been isolated and recognition been taken of the fact that some members are not pathogenic for man. Thus the hemolytic streptococci that might be found in the genital tracts of normal parturient women may be entirely harmless and could not be considered the cause of puerperal sepsis.

Dr. Colebrook seeks to determine the source of infection in a large series of cases of puerperal fever due to hemolytic streptococci and carefully summarizes her observations, determinations and conclusions drawn from her three year study. She compares the strains of hemolytic streptococci isolated from cases of puerperal fever and the extragenital strains found in the patients and their contacts. The strains were identified by three methods of bacteriologic technique. The improved procedures are described. It was satisfactorily shown that the method of absorption of agglutinins can be relied on for the differentiation of stable serologic types of hemolytic streptococci involved in puerperal infection.

In a series of 121 puerperal strains isolated from cases of definite infection it was found that eighty-five reacted with one or another of eighteen of the serums that 85 per cent of these eighty-five strains belong to one of eleven types, and that 54 per cent belong to one of five types. Thus the majority of puerperal strains belong to a limited number of types, and these are the types usually found in diseases of the respiratory passages.

The source of infection of sixty-seven patients was investigated. A possible source was found in 76 per cent. Combined serologic and epidemiologic evidence pointed to the sources in these forty-eight patients. Six patients contracted their infection from their own extragenital strain, twenty-four from an attendant contact and nine from a strain found in a member of the household. Any of the three sources could have been the cause in the remaining nine cases. In a review of other work Dr. Colebrook states that an extragenital source was found in the patient or contact in 75 per cent of 197 consecutive patients having puerperal fever.

The results of recent research show that the hemolytic streptococcus responsible for puerperal infection can be differentiated from other hemolytic streptococci by serologic and biochemical tests that the organisms which cause puerperal fever are not found in the genital tract at the beginning of labor, and that the most important sources of such organisms are in the respiratory passages and in septic foci of the patient and her contacts. Acceptance of the facts so ably presented in Dr. Colebrook's book will do much in reducing the too high incidence of puerperal infection.

**Haemochromatosis** By J. H. Sheldon M.D. F.R.C.P. Hon. Physician to the Royal Hospital, Wolverhampton. Cloth. Price \$8.50. Pp. 382 with 40 illustrations. New York & London: Oxford University Press, 1935.

The material in this monograph formed the basis of the Bradshaw Lectures of 1934. In its present form it is not only a complete summary of the subject of hemochromatosis up to 1934 but is a well organized and carefully edited dissertation that should have permanent value as a text. Unlike most summaries the author has taken the privilege of indicating his own judgment on numerous conflicting issues and has offered a hypothesis that throws some light on the phenomena of hemochromatosis. The material is presented in a readable style. It is comprehensive yet simple and concise and reflects the author's intimate knowledge of the subject. A well selected bibliography of close to 600 references has been skilfully utilized in the organization of the text, and the discussions are convincingly illustrated. The view advanced by the author is that hemochromatosis should be classed as an inborn error of metabolism which concerns the inner metabolism of probably all the cells of the body (with the possible exception of the nervous tissue). The disturbance is expressed in two ways: by a disturbance in the metabolism of melanin (hemofuscin) and by the formation of iron containing pigment (hemosiderin) in nearly all the tissues. Neither appears to be peculiar to the disease. The exact nature of the metabolic error is unknown but the author envisages two possible methods of approach, which he modestly discusses in detail. While this phase of the material is no more than legitimate speculation, it is provocative and logical. The monograph is of interest not only to those specifically interested in the subject of hemochromatosis but to any one concerned with the cellular metabolism of metallic constituents. The book is a valuable addition to any medical library and should be of mutual interest to the clinician and the pathologist.

**Gefässerweiternde Stoffe der Gewebe** Von J. H. Gaddum Prof. der Pharmakologie am University College London. Eingeleitet von H. H. Dale Direktor des National Institute for Medical Research. London. Monographien zur Pharmakologie und experimentellen Therapie. Herausgegeben von Philipp Ellinger. Paper. Price 18 marks. Pp. 200. Leipzig: Georg Thieme, 1936.

More and more it is coming to be believed that stimulation of nerves and muscle is accomplished by secretions exuded by the endings of nerves. In an illuminating introductory chapter in Professor Gaddum's book Sir Henry Dale states: "The evidence is clear that whenever an impulse passes from an autonomic fiber to the cell of an autonomic ganglion acetylcholine is liberated at the synapse. The conception is this that acetylcholine acts as the carrier of each separate preganglionic stimulation, that it stimulates the ganglion cell and thus produces a single postganglionic stimulation, then that at once it disappears. The same conception applies with even greater force to the transmission of impulses from the somatic motor fibers to the end plates in striated voluntary muscle. Here again acetylcholine comes into play. The proof in the case of the muscle is not so conclusive as is that for transmission through the synapses of the ganglions; nevertheless such proof is accumulating rapidly. This topic is of such importance that Professor Gaddum finds it necessary to devote an entire chapter to it with attention not only to acetylcholine but also to sympathin. The evidence at hand makes it appear that sympathin is closely related chemically to epinephrine. In the preface of the book acknowledgment is made for the inspiration received from Sir Henry Dale with whom Professor Gaddum has been associated for several years and who originally was to have been a joint author. In accordance with the purposes of the series of monographs of which this is a member the evidence selected for discussion is that to which the judgment of the author attributes the greatest interest and importance."

The principal topics reviewed in the volume are histamine, acetylcholine, adenosine materials of unknown chemical constitution present in extracts of various tissues, the liberation of specific substances by stimulation of nerves and the liberation of active substances in other tissues. The last topic introduces the concluding section which bears on traumatic shock and the symptom complex of anaphylaxis.

The presentation of each topic is concise and orderly, somewhat after the manner of a compendium but with better style

than the usual compendium has to offer, a style distinctly superior to that encountered in most German medical writing, thus only small familiarity with German is required by the reader. The subject of histamine, for instance, is covered in the following order: (a) its chemical and physical properties, (b) its pharmacologic peculiarities, its action on the circulation, on the lymph on the heart, uterus and other organs, (c) its natural occurrence, its extraction and isolation, (d) its resorption, excretion and metabolism, (e) its physiologic significance.

The bibliography includes approximately 800 references, almost all of them mentioned in the text. The book is a well come addition to the literature on pharmacology.

**The Extra Pharmacopoeia of Martindale and Westcott** Volume II. Published by Direction of the Council of the Pharmaceutical Society of Great Britain. Twentieth edition. Cloth. Price 22s. 6d. Pp. 889. London: The Pharmaceutical Press, H. K. Lewis & Co. Ltd., 1935.

To call a book a gold mine may be unfair to the book when it is as full of priceless information as is the "Extra Pharmacopoeia," a book that is intended to reduce to order and to a manageable compass references to the outstanding original work and the notable advances throughout the whole field of therapeutics. The first volume of this edition is devoted mainly to treatment with drugs and chemicals and the second volume is concerned with matters of diagnosis, analysis and assay of medicinal products and diverse other subjects associated with medicine, chemistry and pharmacy that could not be included in the first volume. The first 300 pages give a wealth of analytic data of interest largely to pharmaceutical chemists. Then follows a brief practical treatise on clinical examinations of urine, blood, feces, stomach contents and cerebrospinal fluid. Under nutrition are discussed foods, vitamins and their estimation, water, milk, flour and bread analysis. Bacteriologic and clinical data with special reference to diseases occupy 120 closely printed pages of practical information, some of which it would be difficult to find elsewhere. Sterilization and disinfectants, chemotherapy and gas poisoning, radium and roentgen diagnosis and therapy, electrotherapy, actinotherapy and proprietary medicines are chapter headings that might serve to illustrate the great variety of material taken up in this volume. The two volumes of the Extra Pharmacopoeia constitute a reference library on matters medical and pharmaceutical that writers, teachers and practitioners who want to be well informed should not try to get along without.

**Allgemeine Röntgenkunde** Einführung in Studium und Praxis der medizinischen Röntgenologie. Von Dr. S. Glasscheib. Second edition of "Die Röntgentechnik in Diagnostik und Therapie." Paper. Price 18 marks. Pp. 502 with 304 illustrations. Vienna: Julius Springer, 1936.

When the first edition of Glasscheib's book came out it had a phenomenal success which was fully justified. For the first time an attempt had been made to give the fundamentals for the understanding of x-ray work from a diagnostic as well as a therapeutic point of view. The success of the book encouraged the author, when finishing the new edition, to widen the scope of the work. Glasscheib now gives his book the title "General Roentgenology." In fact, he has created a work corresponding to the textbooks of general surgery or pathology that have existed for a long time. With his book he provides a work which every physician who devotes himself to clinical x-ray work can use to advantage. The so-called interpretation of x-ray films can be successful only when the manner in which the films are taken is understood and the possibilities of interpretation in relationship to technic and clinical factors are balanced. The biologic fundamentals of the x-rays in living material are set forth and the physics of x-rays is converted from a rather dry and for the practitioner somewhat distant science into an interesting, living aspect of teaching. The material is abundant and it is astonishing with what disposition and exactness Glasscheib has solved his complicated task. The work is subdivided into three parts: (1) roentgen physics, (2) the use of x-rays in diagnostics, (3) the use of x-rays in therapeutics. Each of these parts is subdivided into numerous chapters. The partitions of the whole thing are so clear, the diction so distinct, that one is forced to admire the knowledge and the talent that this young author has submitted for the purpose of teaching. In this edition, the chapters concerning x-rays in

the medical and clinical methods as well as special x-ray pathology are entirely new. Till now, parts of these chapters have been found scattered in special works. Here for the first time they are described exactly and clearly arranged.

**The Foot** By Norman C. Lake, M.D., M.S., D.S., Senior Surgeon and Lecturer on Surgery, Charing Cross Hospital, London. Cloth. Price \$4.50. Pp. 330 with 95 illustrations. Baltimore: William Wood & Company, 1935.

This is written by a physician whose interest in the physiology and the pathology of the human foot is manifested in the enthusiastic presentation of the subject. The discussion begins with a review of the evolution of the foot and continues with a description of the anatomy and physiology. The author does not agree with Keith or with most orthopedic surgeons who hold that the normal arch of the foot is maintained by muscles, while ligaments serve as safeguards and come into use only when the muscular defense is broken down. Lake further argues that the human foot has gradually been growing more rigid through the process of evolution. He explains in part some of the developmental anomalies and particularly the common condition of painful flatfoot or chronic foot strain by further interpretations of this hypothesis. The book includes a brief statement about the various abnormalities of the foot injuries and infections and covers subjects which are ordinarily relegated to the chiropodist but which should be better understood by the specialist and the family doctor. The text is illustrated by diagrammatic sketches, roentgenograms and reproductions of photographs. The general practitioner as well as the orthopedic surgeon is constantly being appealed to for relief from painful conditions of the feet. This book contains information which should help them in treating these patients more intelligently and more scientifically. The major orthopedic procedures connected with the treatment of severe talipes were deliberately omitted. This book should be of interest and help to the chiropodist and the masseuse as well as to the physician.

**I and Me: A Study of the Self** By E. Graham Howe, M.B., B.S., D.P.M., Associate Physician, Institute of Medical Psychology, London. Cloth. Price 7s. 6d. Pp. 236 with 14 illustrations. London: Faber and Faber, Limited, 1935.

The author applies the principle of relativity to the study of life in general and of man in particular, decrying the fallacy of studying things-in-themselves and different qualities as absolutes. He points out that the scientist must recognize an inevitable dualism at every point. For instance, where fear and anxiety are part of the reality of life, the sense of safety is only to be found in accepting danger; and if we use our will power we soon discover something else, namely, that we have a wont power too. The author pleads for science as a method of correlating data obtained from the study of external reality, saying yes to both good and bad, yes to both sides of the balance, accepting the whole of reality as a matter of fact. The book is a philosophical study that will appeal more on a second reading than it will on the first, and the author's skillfully drawn paradoxes are aided by a number of formalistic drawings emphasizing the importance of the middle path and the falsity of fixed absolutes.

**Thérapeutique cardiovasculaire** Par le Docteur P. Schrumphf-Pierron. 1<sup>er</sup>aper. Price 30 francs. Pp. 246. Paris: J. Lefrancis & Cie, 1937.

The writer of this book is obviously not imbued with the critical scientific spirit that must be demanded of a medical teacher or writer in order that his opinion may carry weight. He obviously assumes the attitude of the so-called eclectic who presumes to make a selection of remedies from allopathic as well as 'homeopathic' and other authorities, and to use what seems best according to his judgment and experience. While Dr. Schrumphf-Pierron frequently indulges himself in flings at 'regular medicine' he does not impress one with any special knowledge of his irregular remedies which he deals us with unfortunately so liberal a hand that it would take more a lifetime of many a man to judge them scientifically. This book certainly cannot be recommended as a safe guide to a beginner in therapy. It is rather suitable as a museum piece of eclectic medication.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Workmen's Compensation Acts. Compensability of Pneumonia**—The employee, in the course of his employment, assisted for about two and one-half hours in the grinding of an exceptionally dirty load of grain fodder. The inhalation of the resulting dust and other foreign particles caused him to cough violently and to expectorate a black substance. That evening he continued to cough, complained of his chest hurting, and expectorated blood. After several days of illness he died of pneumonia. After the industrial accident board had denied their claim for compensation, the district court gave judgment for the claimants. The employer's insurer then appealed to the court of civil appeals, Texas.

Plainly said the court a damage to the physical structure of the body need not necessarily be externally visible to come within the meaning of injury, as that term is used in the workmen's compensation act. Naturally, symptoms are depended on in large measure in cases of this character to prove injury to a hidden organ. There was violent coughing, spitting of blood and pains in his chest, almost immediately after the infliction of the alleged injury, and these facts, together with the medical testimony, amply supported the jury's finding that an injury was sustained. If that injury was undesignated and unexpected, had its origin in a risk connected with the employment and is shown to have flowed immediately and directly from that source as a rational consequence it is compensable. In this case the employee labored under unusual conditions. The fodder was the dirtiest that the witnesses had ever seen. There was a mild epidemic of pneumonia in the community. The employer could have but had not provided protective measures. The injury was unexpected and undesignated. It could be traced to a definite time, place and cause. There must of course be a causal connection between the injury and subsequent death of the employee for the latter to be compensable. Here the court said there was sufficient evidence of an injury to the lungs, followed immediately by symptoms indicating a predisposition to pneumonia, which in fact resulted in death occurring therefrom in just one week from the time of the alleged injury. The cause set in motion operated continuously through a sequence of events, each flowing naturally from one to the other, eventuating in death. The court therefore affirmed the judgment of the district court for the claimants.—*Maryland Casualty Co. v. Rogers (Texas), 86 S. W. (2d) 867*

**Malpractice. Fibrous Union Following Fracture of Hip**—The plaintiff, 59 years of age, injured his right hip in 1931 and the defendant, a physician, on the basis of a roentgenogram made a diagnosis of an impacted complete fracture of the surgical neck of the femur. The injured leg was temporarily immobilized with splints and sandbags and after the swelling had subsided a plaster cast was applied. About five months thereafter the cast and splints were removed. Continuing to have trouble with the hip for several years the plaintiff consulted another physician in 1933 whose roentgenologic examination disclosed that the shaft had slipped past the head of the femur for a distance of about two inches, resulting in only a fibrous union. The plaintiff thereafter sued the defendant and obtained judgment in the United States district court, district of Idaho, eastern division. The defendant then appealed to the United States circuit court of appeals, ninth circuit.

It was conceded apparently that the defendant's initial treatment was proper for an impacted fracture but it was contended that he was negligent in his diagnosis and was further negligent in not having taken a second roentgenogram in order to ascertain whether or not the bones were in apposition after the cast was applied. Five medical witnesses testified that the first roentgenogram showed the fracture to be impacted. One medical

witness for the plaintiff testified that, on the basis of the first roentgenogram and the plaintiff's inability to stand on the injured leg, the fracture was unimpacted and that the defective union was due partly to a failure to reduce the fracture by traction and partly to the premature use of the injured leg. Another witness for the plaintiff testified that the defective union might have been caused by either a failure to reduce the fracture or a slipping of the fragments after a proper reduction. The defendant testified that he did not take a second roentgenogram because his measurements showed the bones were in position at the time he placed the patient in the cast and that he made such additional examination and manipulation at that time as was necessary to ascertain that fact. There was no evidence that physicians in that locality were in the habit of taking more than one roentgenogram in a fracture case such as the one involved in this case, or of making any examination other than such as was made by the defendant. The treatment given the patient before the leg was placed in a cast was in accordance with the diagnosis and conceded to be correct for an impacted fracture. If, the court said, a physician has the knowledge and professional skill equal to the average in the locality where he is practicing and exercises that knowledge without negligence, he is not liable for a mistake or error in judgment. Said the court:

In view of the opinion of the large number of professional witnesses to the effect that this was unquestionably an impacted fracture and was so shown by the x-ray pictures taken at the time and in view of the fact that the opposing testimony of Dr. Rich merely goes to the expression of his opinion that the fracture was unimpacted and does not purport to show that there was negligence in diagnosing the fracture as an impacted one even if we assume as the jury may have believed and found that the fracture was not reduced it would still be true that we have nothing more in the case than an error of judgment and no proof that the appellant did not exercise such professional skill and care as were reasonably to be expected in that locality.

The court concluded, therefore, that the plaintiff could not recover having failed to establish that there was negligence in the initial treatment of the fractured leg and having failed to establish that the faulty union complained of was the result of any other act of negligence on the part of the defendant—*Moore v. Tremelling* 78 F. (2d) 821.

**Pharmacists Liability for Sale of Mineral Oil Contaminated with Formaldehyde**—The plaintiff purchased some mineral oil from the drug store owned by the pharmacist-defendant and gave a portion of it to his infant child. The infant became ill almost immediately and ten days later died of ileocolitis or inflammation of the bowel. The plaintiff as administrator of the estate of his deceased son, sued the pharmacist-defendant and the clerk who had dispensed the oil, contending that the oil was contaminated with formaldehyde. At the close of the evidence, the case was dismissed as to the clerk, but the jury returned a verdict against the pharmacist, who thereupon appealed to the Supreme Court of Minnesota.

In the opinion of the Supreme Court, there was sufficient evidence to justify an inference that some one connected with the pharmacy had carelessly permitted formaldehyde to get into the mineral oil that a quantity of it was sold to the plaintiff and administered to the child, and that the child died as the result thereof. The pharmacist contended, however, that the judgment in favor of the clerk was a conclusive bar to a judgment against him, arguing that the liability of the master is derivative and depends solely on the negligence of the servant. With this contention the court could not agree. Whatever might be the result if the pharmacist's liability depended solely on the act of his clerk, the court said, there was abundant evidence of responsibility aside from the sole act of sale. The real cause of death lay in the carelessness which resulted in formaldehyde being mixed with the oil. The record was silent as to how this occurred and certainly does not fix the blame on the clerk. Furthermore, *Mason v. Minn. St.* 1927, Sec. 5813 provides that—

Every proprietor or manager of a place where drugs are sold shall be responsible for the quality of all drugs, chemicals and medicines sold by him.

This section was not enacted to relieve pharmacists of any responsibilities but to afford additional protection to the public. The pharmacist's liability, therefore, is not predicated solely on the negligent act of the clerk but is imposed on him by his

responsibility for the quality of his drugs. The jury was justified by the plaintiff's testimony in finding that the quality of the oil had become dangerously impaired prior to the sale by the clerk. Had the same adulterated oil been sold in some way by an automatic vending machine instead of by the clerk, the pharmacist's responsibility under the statute would be quite clear. The court accordingly affirmed the judgment against the pharmacist—*Berry v. Daniels (Minn.)*, 263 N. W. 115.

## Current Medical Literature

### AMERICAN

The Association Library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Intrinsic Factor in Gastric Juice of Pernicious Anemia**—Goldhamer points out that, while the hypothesis of Castle, Townsend and Heath is of the greatest importance, it does not explain adequately (1) the characteristic spontaneous remissions that occur in pernicious anemia (2) why patients in relapse have variable red blood cell counts, and (3) why those patients with pernicious anemia who apparently have no "intrinsic" factor in their gastric juice are able to produce at least some mature red blood cells despite the specific conclusion that the intrinsic factor must be present in order to accomplish this. In an attempt to explain some of these questions, experiments were performed with gastric juice obtained from patients with pernicious anemia in relapse. The patients selected were proved to have pernicious anemia by their history, physical appearances and laboratory procedures. The red blood cell counts were made on a Neubauer-Levy counting chamber. The hemoglobin was calculated in a Sahli hemoglobinometer according to the recently modified method of Osgood and Haskins. The reticulocyte counts were made on brilliant cresyl blue stained coverslip preparations and on each occasion 1000 red blood cells were counted. The author found that the intrinsic factor of Castle is present in the gastric juice of patients with pernicious anemia in relapse. The deficiency of the gastric secretion in pernicious anemia appears to be quantitative rather than qualitative. The red blood cell count in relapse, falls to a level determined by the amount of intrinsic factor which the patient is able to secrete in his gastric juice. Apparently erythropoiesis depends in part at least on the action of the intrinsic factor and the rate of red blood cell formation is related to the amount of the intrinsic factor produced. Spontaneous remissions still remain in the realm of speculation.

**Treatment of Coronary Disease by Saline Injections**—Three years ago, Feinberg gave a patient having arteriosclerotic closure of the leg vessels and coronary disease intrave-

nous therapy accidentally before a cardiac examination was made. Three injections of 5 per cent sodium chloride solution of 300 cc each had been given to the patient before the diagnosis was known. During the following three years of this treatment he had only one episode of angina. At the present time he receives a weekly injection of 300 cc of a 5 per cent solution of sodium chloride. Today he can walk any distance without symptoms. During this period fifteen other patients with combined arteriosclerotic closure of leg vessels and coronary artery disease have been treated with intravenous injections of hypertonic solution of sodium chloride. No untoward accident has occurred. The results in these fifteen cases appeared so promising that six intractable cases of angina pectoris due to coronary artery disease without arterial involvement of the extremities were selected for special study. The group consisted of five cases of angina pectoris following coronary artery thrombosis and one case of coronary sclerosis in a diabetic patient. These patients had had coronary artery disease for at least six months and had not improved under the ordinary course of treatment. None of the six patients could walk one block without being stopped by precordial pain or dyspnea. The initial dose was 100 cc of a sterile 5 per cent sodium chloride solution. Subsequent doses were increased by 50 cc weekly up to a maximum of 250 cc. Injections were given three times a week. If precordial pain occurred during or immediately following the increased intravenous injection it was evident that the heart was not ready for it. The author continued the therapy with the previous dose for a period of three weeks. The increased dose was then retried and was in every case successful. A graduated 300 cc buret was used and the solution was given intravenously by gravity. The buret was about 3½ feet above the patient, who was lying horizontally. Patients were not hospitalized and came to the clinic unattended. These patients did not receive any drugs or other treatment after the intravenous injections were begun. Striking improvement occurred in all evinced by definite and continuous clinical improvement. No claim is made that the arteriosclerotic process responsible for this disease is arrested. The treatment was employed in an attempt to increase the collateral circulation. The intravenous administration probably favors the development of collateral circulation through the finer ramifications of the coronary system. In selecting the first cases care was taken to avoid those that showed nephritis, cardiac decompensation, cardiac arrhythmia and arterial hypertension over 180 mm of mercury. The hypothesis is presented that the clinical improvement may be due to the fact that the treatment encourages a more rapid development of collateral circulation in the wall of the heart.

**Bismuth by Mouth in Treatment of Experimental Syphilis**—In a study of the oral administration of bismuth in the treatment of early syphilis in the rabbit, Kemp and Rosahn found that 1 Twenty-four daily doses each of 20 mg of metallic bismuth as contained in a complex amino acid bismuth salt (bismutrate) per kilogram failed to alter materially the course of early syphilis in five of the six animals treated. Two of the four animals which were given twenty-four doses of 50 mg per kilogram developed generalized lesions during treatment or a short time after it ended. The two remaining animals were still negative forty-one days after the experiment ended. The one animal that died after the sixth treatment still harbored actively motile spirochetes in the originally infected testicle. 2 Six animals fed twenty-four doses each of 20 mg of metallic bismuth per kilogram as contained in bismuth sodium iron citrate experienced no change in the course of the infection, developing metastatic lesions in the testicle opposite to that inoculated in every instance. 3 Seven of eight rabbits fed potassium bismuth tartrate in doses of 20 mg per kilogram still showed actively motile spirochetes in the inoculated testicle after the twenty-fourth treatment. Seven of the eight also developed metastatic lesions in the opposite testicle during or within twenty days after the treatment was terminated. 4 The results of the Kolmer blood Wassermann and Kahn tests, performed according to a technic modified for rabbits gave no index of the course of the infection during treatment. 5 The study supports the observation of Serefis that it is impossible to use the syphilitic rabbit in determining the value of bismuth preparations intended for oral administration in the treatment of human syphilis.

**Orientation of Venous Valves in Relation to Body Surfaces**—Edwards describes a seemingly constant orientation of the valves of veins of the extremities. The vein at the site of a valve is elliptic in cross section the major axis of the ellipse being parallel to the skin or its tangent. Within the vein at the site of the valve the two cusps arise from the long curves of the ellipse so that the aperture between their free margins is also parallel to the overlying skin. The advantage of this arrangement is that the compression transmitted to the veins by overlying structures produces secure apposition of the cusps to each other and thereby ensures the competence of the valve. The demonstration of the relationship of venous valves to the overlying skin is based on anatomic dissections and on roentgen studies of the living subject. Presumably a

similar relationship exists between venous valves and adjacent surface planes in the interior of the body. Actual observation, however, has been extended only to one fairly constant valve in the external iliac vein, in which the cusps are definitely oriented in a plane parallel to the parietal peritoneum.

**Treatment of Lupus Erythematosus with Gold Compounds**—Wright discusses the cases of seventy-six patients with lupus erythematosus, for whom the outlook was hopeless who were treated during a period of ten years with gold compounds chiefly with gold and sodium thiosulfate. Twenty-eight patients are regarded as cured, twenty-six were almost cured or were greatly improved, thirteen were improved moderately or slightly and nine failed to respond favorably to the treatment. Of the patients regarded as cured two have been well with no relapse for seven years, two for six years, two for five years and three for four years. The amount of gold and sodium thiosulfate required for cure varied from a minimum of 12 mg in one patient to a maximum of 2750 mg in another. Thirteen patients suffered one or more relapses after being partially or entirely free from lesions. In some patients the lesions cleared again following further treatment with the drug, and some were discouraged and refused further therapy. Nineteen of the patients suffered a reaction of one type or another from the gold. The commonest was a scarlatiniform dermatitis, which occurred in eight cases. No fatality occurred in the series except in one case in which dissemination of the eruption and death occurred following the use of a foreign preparation of gold. The safety of administering gold compounds has been greatly enhanced by a better understanding of dosage and of the warning signs of intolerance, which lead the physician to take measures to prevent serious accidents. It is the author's distinct impression that the percentage of cure would be even higher with modern therapy if entire cooperation by the patient could be achieved, for certainly in some cases improvement could have become cure by additional therapy.

**Annular Granuloma**—Goodman and Ketron report two cases of annular granuloma which show, besides typical lesions those of a large circinate type resembling the lesions of toxic erythemas. A detailed study of the histopathologic character of the disease, based on a total of twelve cases, is presented showing the various gradations from early changes as illustrated in the erythematous manifestations to those found in the later stages present in the more characteristic lesions. From their studies they believe that annular granuloma presents a characteristic histologic picture, particularly in the early stages in which the first changes appear to be a granular degeneration of the connective tissue, either diffuse or localized in more sharply circumscribed areas. This is followed by a cellular infiltrate of large mononuclear cells of the macrophage type which with connective tissue cells, tend to arrange themselves between the partially degenerated fibers or around the edges of circumscribed necrotic zones in a characteristic manner. Although there was a considerable perivascular inflammatory reaction present no marked occlusive changes were found in the blood vessels, and they show no particular relationship to either the early or the later necrotic changes in the connective tissue. Polymorphonuclear neutrophilic leukocytes, although occasion

ally found, are strikingly absent in all stages of the disease. Occasionally plasma cells and eosinophils are encountered. In the later stages, annular granuloma resembles histologically the juxta articular and rheumatoid nodules in certain cases except with respect to the vascular changes found in the latter.

**Cutaneous Tags of the Neck**—Templeton describes lesions that begin as tiny flesh colored papules ranging in size from a pinpoint to a pinhead. They occur almost invariably on the necks of middle-aged women, being most common on the lateral and anterior aspects, occasionally appearing on the chest. They vary in number from a few to hundreds. While most of them remain as papules about a millimeter in diameter, a number grow to the height of 1 or 2 mm and exist as pedunculated filiform tags. In general they retain the normal color of the skin, but a few become slightly darker. They do not tend to grow to the size attained by the tumors seen in cases of Recklinghausen's disease. As it has been suggested that this disorder might be related to Recklinghausen's disease he examined many patients with this disorder, without finding a single example of neurofibromatosis of the trunk. Microscopic observations demonstrated that the tags are not tumors of fibrous tissue origin. Moreover, the negative results with the Van Gieson stain militate against their arising from nerve tissue and constituting a sign of Recklinghausen's disease. Cutaneous tags of the neck need to be differentiated from digitate warts and molluscum fibrosum, histologically, they show a relatively simple outgrowth or excrescence of epidermis and corium while the lesions of molluscum fibrosum show a typical growth of neurofibromatous tissue in the corium. The author has found that the best treatment is to destroy each lesion with a very fine electrodesiccating spark. It is his belief that they constitute an entity apart from warts and fibromas and he suggests the name cutaneous tags of the neck.

\*Immunologic Aspect of Tobacco in Thrombo-Angiitis Obliterans and Coronary Artery Disease A Trasoff G Blumstein and M Marks Philadelphia—p 250

**Tobacco, Thrombo-Angiitis Obliterans and Coronary Artery Disease**—The studies of Trasoff and his associates do not justify the contention that hypersensitiveness of the vascular system to tobacco is the mechanism in thrombo-angiitis obliterans and coronary artery disease. They have frequently noticed direct relationship between vascular crises and smoking whether symptoms occurred in the lower extremities or in the coronary system. Three patients with thrombo-angiitis obliterans and four with coronary disease volunteered the information that smoking initiated pain. Definite electrocardiographic changes were demonstrated during the process of smoking in a few patients. On a pharmacologic basis only tobacco or its derivatives react directly on the sympathetic nervous system causing a vasoconstriction which is manifested as an increase in blood pressure and pulse rate with a lowering of the surface temperature of the skin. Nicotine may not be the element at fault and there are still many toxic substances in tobacco which cannot be eliminated definitely. The authors state that while their series is relatively small the results are uniform. The only group in which the percentage of positive skin tests was comparatively high was the allergic. It is known however that many nonspecific reactions are frequently obtained in such individuals. Of sixty-three unselected asthmatic children from the ages of 3 to 12 years whom Chobot tested to various tobacco extracts, only six gave negative skin tests. Tobacco apparently was not an etiologic factor in their asthma. The incidence of crises in which tobacco is a proved

atopen is not very great. According to Brown, tobacco accounts for 1 per cent in the nosology of his asthmatic patients, while in the authors' experience it amounts to less than 1 per cent. The failure to demonstrate reagins for tobacco on passive transfer tests in all patients except one, who reacted to tobacco, also argues against its significance in allergy. Of the hundreds of allergic patients whom they have studied they do not recollect any with thrombo-angiitis and no greater proportion of coronary disease than one ordinarily meets among the non-allergic persons about the fifth decade of life. There is no essential difference in skin reactivity to tobacco between the normal smokers and nonsmokers.

**Diuretics in Treatment of Cardiac Edema**—Wood states that rest in bed proper digitalization and restriction of fluid intake will produce loss of edematous fluid in many cases. More dramatic improvement has occurred in patients with auricular fibrillation though patients having congestive heart failure with normal rhythm may benefit markedly from full digitalization. In patients with cardiac edema quite satisfactory diuresis not infrequently accompanies rest in bed alone. A period of observation during rest and digitalization is necessary. The author's study in diuresis attempts to set forth his experience with patients in whom frequently it has been expedient to administer certain drugs rather than adhere to experimental uniformity. During the actual period of marked diuresis following drug administration the fluid intake should be temporarily increased. Rigidity in the limitation of water is unwise in this respect and elasticity would seem a safer and more comfortable policy for the patient. Instances of temporary psychosis following rapid dehydration are frequent enough to draw attention. Unfavorable body changes may follow too rapid dehydration and whereas no conclusive data are available at present an attempt should be made to meet the drive of excessive water output with a somewhat increased intake. Ordinarily only the specific diuretics, particularly those used intravenously cause single drive or tremendous urinary output. Generally diuresis following rest and digitalis comes on and fades gradually and it would seem that adjustment to dehydration would therefore occur with less disturbance. For this and other reasons digitalis and fluid restriction are tried first in the treatment of cardiac edema. However, these measures while sufficient for some, may be temporary and incomplete in many patients. Numerous substances have been recommended for their diuretic effect but the author's discussion includes only the xanthine and mercurial diuretics and their combined action with certain inorganic salts. Xanthine diuretics should be tried after digitalization and before

turning to the mercurial drugs. Noteworthy of the xanthines is their better action in patients with hypertensive and arteriosclerotic heart disease. They are less effective in rheumatic heart disease. Presumably the xanthines primarily increase filtration, while the mercurial diuretics decrease reabsorption. The value of diuretics in the treatment of cardiac failure need not be questioned. Generally speaking patients with hypertensive and arteriosclerotic heart disease respond best to diuretic drugs. Should rest, fluid restriction, diet and adequate digitalization fail in the treatment of cardiac edema, the xanthine and mercurial diuretics should be tried preferably in the order mentioned. Combination of these drugs with certain salts and with one another may promote diuresis. The diuretic drugs should not be used as a last resort, as edema may increase cardiac work and impair cardiac efficiency, and the early use of suitable diuretic drugs may therefore have a double advantage.

**Fusospirochetal Lung Infections in Children**—Taggart presents an account of fusospirochetal pulmonary infection in a white male infant 14 months of age. The original infection had its beginning in the form of a gingivitis which led him to assume that the lung involvement was an aspiration phenomenon. The patient has been irregularly followed for a year and a half during which time the process has gradually improved and his growth and weight gain have been uninterrupted in spite of the added insult of attacks of grip and measles. Because of the proximity of some of the abscess cavities to the pleural surface surgical intervention was considered inadvisable. Bismuth preparations were decided on because of the child's evident low systemic reserve the evidence of an extreme degree of cloudy swelling of the liver and unusual demands on the hematopoietic system. Arsenical acetarsone was employed for about ten days without any apparent remarkable change in an already improved condition.

**Influence of Adrenals on Calcium Metabolism**—Schour and Rogoff state that the occurrence of globular predentin in adrenalectomized rats as in animals that were subjected to the action of parathyroid extract confirms the observation that adrenal insufficiency is associated with disturbances in calcium metabolism. It also lends support to the suggestion of a functional interrelationship between the adrenals and the parathyroids. It seems possible that the disturbances in calcium metabolism which lead to the changes in the dentin in adrenalectomized animals may be the result of functional distur-

bances in the parathyroids. Although evidence favors the probability that the adrenal cortex is primarily involved, the possible relation of the medulla has not been excluded in these experiments.

**Wandering Bullet in Spinal Canal**—In the case reported by Pilcher the bullet entered the spinal canal from the anterior side, reaching the free space in the canal posterior to the cord or cauda equina without having done much damage to these structures or to the bones of the vertebral column. The question arises as to whether the injuries to the nerve were due to the bullet or whether they resulted from compression of the nerves by a large hematoma lying anterior to the spine. The only analogous case found in the literature is that reported by Fergor, whose patient had a bullet in the spinal canal at the upper lumbar level without any neurologic symptoms. Regardless of whether the bullet was the direct cause of the nerve injury in the present case, it is certain that it would sooner or later have caused trouble and that its removal was indicated. The bullet in the present case is known to have moved freely both up and down the spinal canal and its position could be changed at will by altering the patient's position. It seems likely that it was pushed ahead of the exploratory catheter at the time of the first spinal exploration. The case serves as a warning that the exact position of foreign bodies thought to be in the spinal canal should be determined immediately before the exploration for their removal.

**Osteochondritis Dissecans as Related to Trauma**—In Funsten and Kinser's series of twenty-three cases of osteochondritis dissecans seventeen gave a definite history of trauma to the involved joints. One of the remaining six patients spent many hours daily working on his knees. One case was associated with rupture of the internal semilunar cartilage and, following the removal of the cartilage and osteochondilaginous body there was entire freedom from symptoms in four weeks. The classic case of osteochondritis dissecans shows on roentgen examination involvement of the inner condyle of the femur. The lesion was bilateral in three of the reported cases in the patella head of the femur and acetabulum. A case with osteochondritis dissecans of the carpal scaphoid and another of the semilunar are reported.

\*Splenectomy for Thrombocytopenic Purpura Gwendoline Smith—p 157

**Splenectomy for Thrombocytopenic Purpura**—Smith reports a case and believes that until more knowledge of the pathology of thrombocytopenic purpura is gained the value of any one method of treatment must be based on isolated records. Evidence is in favor of the spleen being only one part of a diseased reticulo endothelial system and some observers do not recommend splenectomy on the ground that only partial removal of the diseased tissues is effected. It seems that the spleen is certainly one of the largest single structures affected and if clinical results show that patients are improved and remain well, it would appear wiser to base treatment on these results. The actual platelet count is not a certain index of the severity of the disease or of the degree of recovery after operation. The platelet count may rise as soon as the splenic vessels are secured but may not show any increase for some days later. The criterion of permanent recovery is freedom from hemorrhages and purpura over an indefinite number of years. The presence of accessory spleens is occasionally a cause of recurrent symptoms, and they should be looked for at operation and removed if found. In a certain number of cases a long period of good health has been assured by operation in the acute and chronic states of the disease. In acute cases that fail to respond to medical measures the mortality without surgical intervention is in the region of 100 per cent. In chronic cases the indications are not so clear, but splenectomy would appear advisable in those of moderate severity which fail to improve with drugs and blood transfusions or suffer from acute exacerbations of purpura, with a persistent low platelet count. Cases of mild severity will respond to treatment of anemia and removal of septic foci. A certain percentage of recurrences must be expected but one may anticipate that even then the symptoms will gradually lessen and eventually disappear in the majority.

**Exophthalmos Following Administration of Thyroid Extract**—Brain states that the difficulty of explaining exophthalmos is enhanced by the fact that the administration of thyroxine or of thyroid extract whether experimentally to animals or therapeutically to man does not as a rule lead to exophthalmos. Not more than twenty such instances have been reported. The development of progressive exophthalmos in patients who have previously undergone subtotal thyroidectomy for thyrotoxicosis is a closely related phenomenon since this may be precipitated by the administration of thyroid extract to correct postoperative hypothyroidism. A new case of exophthalmos following the administration of thyroid extract is presented. The significance of this sequence of events is discussed in the light of this and previously reported cases and of recent experimental work on exophthalmos. Exophthalmos can be produced experimentally by the administration to animals of drugs that stimulate the sympathetic nervous system. Thy-

roxine appears to facilitate the action of such drugs in producing exophthalmos. Exophthalmos can be produced by the thyrotropic hormone of the pituitary both in intact animals and in animals from which the thyroid has been removed, and there is some evidence that this hormone produces exophthalmos more readily in the presence of hypothyroidism. Progressive exophthalmos may develop spontaneously following subtotal thyroidectomy in man even when the basal metabolic rate is subnormal, or may be precipitated in such individuals by the administration of thyroid extract. Very rarely the administration of thyroid extract for the treatment of myxedema, the relief of obesity or some other purpose is followed by the development of exophthalmos. It is probable, therefore that, when exophthalmos follows the administration of thyroid extract, this is not a direct result of the action of the thyroid extract but is due to some other substance which in certain rare individuals is produced in response to thyroid extract. Experimental evidence suggests that this substance may be the thyrotropic hormone of the pituitary.

Diet and Health in South Africa II Malnutrition F W Fox—p 25

**The Modern International Type Classification of Leprosy**—Germond gives the new international classification of types of leprosy. First as regards the definition of the most important terms. 1 It is suggested that the term 'leprotic' be applied to changes that present clinical or microscopic evidence of inflammatory processes typically of granulomatous nature which are apparently caused by *Mycobacterium leprae* in them. In such lesions the organism can usually be demonstrated by the ordinary methods of examination. 2 'Infiltration' is a term commonly applied to a diffuse thickening of leprotic nature involving the skin or mucosa which is not of definite nodular papular or macular form. The term may also be applied to diffuse leprotic conditions in other organs. 3 A nodule is a definitely thickened, rounded, circumscribed mass of leprotic nature commonly occurring in the skin subcutaneous tissue or mucosa. 4 A papule is a small solid elevation of the skin of leprotic nature not more than 5 mm in diameter. 5 A macule is a circumscribed area of skin showing changes in color sometimes with slight elevation or depression. Secondly the proposed classification is given as follows. All neural (N) cases are those that show evidence of actual or previous neural involvement alterations of sensation with or without changes in pigmentation and circulation trophic disturbances or paralyses and their consequent results atrophic contractures ulcerations. These are not accompanied by leprotic changes in the skin. All cutaneous (C) cases are those that show leprotic lesions in the skin. Such cases may or may not show at any given time clinical manifestations of neural involvement. Subtypes are classed NI, NII and NIII on the one hand, and CI, CII, CIII on the other according to the degree of severity. In all cutaneous types there may be varying degrees of neural involvement and such cases should be recorded to indicate the degree of involvement as for example C<sub>N1</sub>. Secondary neural are those neural cases that were formerly cutaneous but from which the active leprotic lesions have disappeared.

Optic Neuritis of Pentavalent Arsenic P de Font Reaulx—p 73

**Reduction of Infantile Scolioses**—Le Cam has previously described a law which he believes is valuable in the correction of infantile scoliosis. This law may be stated as follows: If a shoulder is maintained in an elevated position, it results in the hypertrophy of the corresponding hemithorax and the atrophy of the opposite hemithorax. It thus forces the vertebral column to curve and inevitably produces the formation of a scoliosis the convexity of which is toward the side of the raised shoulder. A number of cases of infantile scoliosis have been treated by applying this law. When properly performed there is no necessity to fear that the shoulder which was raised by the aid of an elastic tampon will remain raised after the end of the treatment. All scolioses of nurslings treated immediately are cured rapidly and permanently. Later the reduction of the curve is obtained rapidly if it is of recent origin and not too pronounced. The less exaggerated scolioses remain treatable for a longer time. He recommends this treatment as a relatively simple and effective method of meeting the problem of scoliosis in infants and children.

**Intravenous Chromoscopy in Achylia**—Allodi and Quaglia performed gastric chromoscopy after an intravenous injection of 0.005 Gm of neutral red in 10 cc of distilled water in sixty-five patients suffering from achylia which persisted in all but fifteen cases in the group after the administration of Ewald's meal and in about half the number of patients after performance also of the histamine test. The results of chromoscopy are considered negative when the dye fails to appear in the gastric juice within seventy minutes of the intravenous injection. Chromoscopy gave late positive results in half the number of patients of the first group and negative results in the other half. In the latter subgroup however, the results became positive by performance of the histamine test immediately after failure of chromoscopy. In patients of the second group chromoscopy gave negative results which were not modified by the performance of the histamine test immediately after failure of chromoscopy except in four cases. The authors conclude that chromoscopy is not a substitute for the histamine test in the diagnosis of achylia but it has a complementary value to the test. The results of the latter are analogous to those of the former but they are not constantly in mutual accordance with each other. The authors advise a chromoscopy in all patients in whom achylia persists after administration of Ewald's meal regardless of the results either positive or negative of the histamine test and also the histamine test immediately after failure of chromoscopy. The failure of the latter after the failure of the histamine test is probatory for the existence of complete achylia. The technic of chromoscopy is easy and no unfavorable complications follow its performance.

**Velocity of Blood Circulation from Cubital and Dorsal Veins**—Bertola made determinations of the velocity of circulation in fifty persons aged from 18 to 80 including normal persons and patients suffering from cardiac diseases anemia, ascites edema and certain infections. The circulation time was measured by the calcium chloride method from the cubital vein or the arm and the dorsal vein of the foot to the arteries of the head. The author found that the velocity of circulation is

greatly diminished in cardiac diseases, especially in the stages of decompensation. Circulation from foot to head is slower than circulation from arm to head in cardiac patients, a fact that is explained by the modifications of the venous pressure and the existence of stasis. The velocity of circulation, both from the cubital and the dorsal veins, is increased in anemia, and the more intense the anemia the more rapid the circulation. The relation between the rapidity of circulation and the intensity of anemia is not constant, however, and there are many patients suffering from intense anemia in whom the circulation time is either normal or retarded. The increase of the velocity of circulation in anemia is due to a mechanism of compensation connected with the diminution of the power of oxygenation of the blood. Normal or retarded circulation is probably due to myocardial insufficiency, which interferes with the establishment of the compensatory mechanism. Circulation from both the cubital and the dorsal veins is increased in febrile diseases of the respiratory tract, probably owing to the increased output of blood during fever and the resulting increased frequency of the pulse. It is normal in patients suffering from abdominal tumors with ascites and edema as well as in diabetic patients.

**Bronchial Factor in Ayerza's Disease**—Castex and his collaborators performed bronchography in seven patients suffering from Ayerza's disease. In all cases the picture of the bronchial tree was that of the so-called winter tree, in which the branches (bronchi of large caliber) but not the foliage (bronchi of small caliber) could be seen. The bronchographic aspect of the "winter tree" is due to retention of iodized poppy-seed oil in the bronchi of large caliber and it is a characteristic of either chronic bronchitis with dilatation of the bronchi or diffuse sclerosis of the lung and emphysema. The retention of iodized poppy-seed oil in the bronchi of large caliber shows that the alveolar part is involved in the pathologic process earlier than any other segment of the tree. The condition interferes with the aspiration of air by the alveoli and its entrance in the alveoli and also with the diffusion of gases through the alveolar endothelium. Insufficient inspiration and expiration follows and as a result the syndrome of hypoxemia and hypercapnia develops. The constant presence of chronic bronchitis and subsequent dilatation of the bronchi in all the authors' cases prove their statement that cardiovascular insufficiency and the metabolic disturbances of Ayerza's disease are secondary to respiratory insufficiency due to chronic bronchitis and its sequelae. Dilatation of the bronchi is selectively located in the bronchi of large caliber and intensifies itself as the disease progresses. It is interpreted by the authors as caused by a detrimental action of chronic bronchitis on the structure, elasticity and kinetics of the bronchi. Dilatation was of the bronchiectasis cylindrical type in all the authors' cases which explains the lack of fetor in the bronchial secretions of patients suffering from Ayerza's disease. The dead space was increased in proportion to the intensity of bronchial dilatation in all cases. The anatomopathologic study of the bronchial lesions confirmed the part that chronic bronchitis played in the onset and evolution of the syndrome of Ayerza's disease.

\*Treatment of Epidemic Meningitis with Roentgen Rays H Hippe and U Gruninger—p 304

\*Is Ice Bag Advisable in Gastric Hemorrhages? M Dobreff—p 308

**Treatment of Epidemic Meningitis with Roentgen Rays**—Hippe and Gruninger direct attention to a former report on the use of roentgen rays in meningitis (abstracted in THE

JOURNAL, Sept 8, 1934, p 793) and describe their more recent experiences with this treatment. They report the histories of two children with epidemic meningitis, in whom roentgen irradiation has had a favorable effect on the signs of irritation that remained after treatment with lumbar puncture meningococcus serum and blood from adults. In the first child the rays were applied to five cranial fields (two temporal fields and one each in the frontal parietal and occipital regions) and one cervical field. The irradiations were made on six successive days each field receiving 150 roentgens. The tension was 180 kilovolts the current strength 6 milliamperes the filtration 0.5 mm of copper and 1 mm of aluminum, the distance 30 cm and the size of the fields 8 by 10 cm. In the second case the rays were applied to five cranial fields (120 roentgens each). In the conclusion the authors point out that they do not expect from the roentgen treatments an influence on the causal organism as such but they aim to reduce the secretion of the choroid plexus and thus the pressure of the cerebrospinal fluid. On the other hand they think that the anti-inflammatory action of the roentgen rays exerts a favorable influence on the inflamed meninges. Since in the roentgenotherapy of inflammations not only the dosage but also the time of the treatment is important they suggest that the usual treatment be employed (lumbar puncture with removal of the cerebrospinal fluid and serotherapy) during the acute stage of the meningitis. However, if this treatment does not result in the complete disappearance of fever and of the meningeal signs, roentgenotherapy should be resorted to.

**Use of Ice Bag in Gastric Hemorrhages**—Dobrefi reviews the literature on the subject and finds that although there are some contradictions, the majority of the investigations indicate that the application of the ice bag results in an increased kinetic and secretory action of the stomach. Since the increased activity of an organ is accompanied by a greater blood perfusion, it becomes evident that the application of the ice bag produces the exact opposite effect of that which is desirable in case of gastric hemorrhages. Since the definite solution of this problem is of considerable importance the author studied the effect of the ice bag on the motility, secretion and visible changes in the gastric mucous membrane in a woman in whom a gastric fistula had to be made on account of complete stenosis of the esophagus. In other respects the woman was healthy. The direct observation of the inside of the stomach was done by means of Kalk's laparoscope introduced by way of the fistula. It was observed that the application of the ice bag to the skin in the region of the stomach resulted in an increase of the peristalsis, hyperemia of the mucous membrane and increased secretory action whereas the application of a hot water bag had exactly the opposite effect, namely reduction of the peristalsis, anemia of the mucous membrane and reduction of the secretory action. On the basis of these observations and of reports in the literature the author concludes that the application of the ice bag is contraindicated in gastric hemorrhages.

**Hepatorenal Syndrome**—Faltitschek and Hess point out that cellular impairments of the liver if they reach a severe degree cause disturbances in the water exchange. Edema has been observed in patients with hepatic diseases in which cardiac and renal causes could not be detected. Water retention has been noted in catarrhal icterus, and it is also known that the water elimination increases as soon as the jaundice subsides in these cases. In acute atrophy of the liver one of the typical symptoms is oliguria and occasionally anuria. Then there is biliary cirrhosis in which decrease in temperature and the disappearance of jaundice is accompanied by polyuria. However, in addition to the hepatic there is also a renal factor concerned

in the disordered water economy of patients with liver disease. The occurrence of icterus cylinders and frequently a mild albuminuria indicate an anatomic lesion of the kidney but in addition to this it may be assumed that the liver influences the water economy by a hormone action on the kidney. The authors demonstrate that this renal factor plays a rather important part in the clinical and pathologic aspects of liver diseases. In regard to the pigment elimination they point out that hemolytic icterus which is accompanied by blood decomposition takes an acholuric course because the indirect bilirubin that develops from the decaying erythrocytes is not suited for elimination by the kidneys and accumulates in the blood. The authors demonstrate that even the direct bilirubin fails to pass the kidney under certain conditions in spite of the fact that it is present in the blood in amounts far in excess of the physiologic measure. In such cases icterus and acholuria appear in spite of considerable direct bilirubinemia. The authors report three cases. The episodically appearing icterus was not of hemolytic origin; this is proved by the pigment content of the feces, the absence of an impaired resistance of the erythrocytes and the presence of direct bilirubin in the serum. Although the latter reached high values in the serum there was no bilirubinuria because the kidney had lost its capacity to eliminate bile pigment. With the return to normal renal function the excessive amounts of bilirubin disappeared from the blood. The authors cite other cases from the literature that resemble the ones observed by them.

- New Proofs for Pathogenic Significance of Trichomonas vaginalis M. Rodecurel—p 567
- Treatment of Leukorrhoea in Virgins G. Bakics—p 568

**Radium Treatment of Menopausal Hemorrhages**—Anselmino says that in spite of the increasing use of radium treatment in menopausal hemorrhages there is no general agreement regarding the dosage and the type of cases in which it is advisable. He shows that some apply doses upward to 3000 mg element hours others use doses as small as from 600 to 800 mg element hours and many now apply doses of 1200 mg element hours. At his clinic the doses have been steadily decreased from as high as 3000 mg element hours in 1928 to around 1000 mg element hours in recent years. Before evaluating the results of the after examinations of ninety-eight women who in the course of the last several years had received radium treatment for menopausal hemorrhages he discusses the technique. He always precedes the radium treatment by a curettage. Then he introduces 50 mg of radium element which is deposited in units of 10 mg in five silver tubes 0.1 mm in thickness which in turn are enclosed together in a brass container that has a wall thickness of 1.5 mm. In evaluating the results that were obtained at his clinic he finds that the cases that have been treated with doses from 800 to 1200 mg element hours react quite favorably to the treatment in that there was only one failure in fifty cases. A tabular report indicates that the higher the age of the woman at the time of the treatment the better the effect of the rays; that is smaller doses produce the desired effect. The more moderate doses have the advantage of not causing complications; there are no signs of intoxication and the symptoms of abolished function are mild that is somewhat like those of the normal menopause. Many women complain of leukorrhoea after the radium treatment but this disorder usually disappears in several weeks or months. In discussing the indications for the radium treatment he says that it is hardly ever employed in women under 40 years of age. He himself employs it as a rule only in women over 42 years of age who have climacteric hemorrhages. In these he usually does not differentiate whether a glandular hyperplasia exists

or not. However, in the milder cases he usually limits the treatment at first merely to a curettage. Thus the radium treatment is usually reserved for the more severe cases. For younger women he considers surgical intervention in the form of a supravaginal amputation or of a fundus resection advisable, in that such interventions do not affect the general organism as much as an excision of the ovarian function with radium therapy.

 \*Gastro-Intestinal Obstruction and Chloride Content of Blood V. M. Voskresenskiy—p. 126

**Use of Heterogenous Blood for Shock Therapy**—Ryss and his co-workers believe that allergy with local manifestations in the gastric mucosa is the basis of ulcerative disease in many cases. They obtained arterial blood from a dog and administered it intravenously in doses of from 1 to 15 cc. Two or three injections at intervals of from five to ten days constitute a course of treatment. There were in this group sixty-four cases of intractable recurring ulcer disease and ten cases of recurring ulcer after a gastro-enterostomy. The patients were kept on a liberal ulcer diet from which animal albumins as potential allergens were excluded. Good results were obtained in 80 per cent, satisfactory results in 12 and no effect in 8. The authors selected hemoprotein of heterogenous blood as the most suitable stimulant, because it is nontoxic and does not cause late complications such as paralysis or neuritis, because it possesses considerable antigen qualities due to ready solubility of its albumins and because it raises the cellular metabolism and phagocytosis. It is capable of activating separate organs and systems, in particular the connective tissue and the reticulo-endothelial system. By activating the regenerative and immunobiologic properties of the mesenchyma it favors early healing of the gastric duodenal ulceration. The best results were obtained from a course of three injections of large doses, 5, 10 and 15 cc of blood.

**Blood Chlorides in Gastro-Intestinal Obstruction**—Voskresenskiy reports 428 determinations of blood chloride made in eighty-three patients suffering from acute paralytic or mechanical ileus. He found that a fall in blood chlorides to 300 mg constitutes a grave prognostic sign in cases of acute ileus. Sodium chloride administered intravenously rapidly concentrates within the lumen of the intestine. The greater number of their patients suffering from acute paralytic ileus responded with a lively peristalsis to intravenous infusion of hypertonic solutions of sodium chloride. This effect was not obtained when the intestine was gangrenous. In order to obtain a therapeutic effect in cases of paralytic ileus it is necessary to inject about 200 cc of a 10 per cent solution of sodium chloride.

 \*Treatment of Obesity by Diet Relatively Poor in Carbohydrates P. Hanssen—p. 97

**Urobilinuria Following Water Tolerance Test**—Adlercreutz points out that numerous studies have demonstrated that the liver plays an important part in the water economy of the

organism. Disturbances in the hepatic function are usually accompanied by impairment of the water exchange, and in parenchymatous diseases of the liver an inhibition in the diuresis is often observed. The author describes the water tolerance tests he made on thirteen patients with various disorders of the liver (eight with acute hepatitis, two with hepatic cirrhosis, one with cholelithiasis and two with hepatic stasis). The tolerance tests were made in the form of the ordinary Volhard experiment with 1 liter of water taken in the morning, while the patient is still fasting and in as short a time as possible. After that the urine is collected at hourly intervals for four hours. These specimens are tested as to quantity, specific gravity and urobilin content. The urobilin concentration is determined in the night urine as well as in the day urine and control tests are made throughout the patient's stay at the hospital. Adler's modification of Schlesinger's fluorescence reaction (in the presence of alcoholic solution of zinc acetate, urobilin produces a greenish fluorescence) served for the determination of the urobilin content. All cases of hepatitis with one exception both cases of cirrhosis and one case of hepatic stasis showed a greater or lesser increase in urobilin. The author thinks that this is due to the fact that the water tolerance test increases the bile secretion and thus causes the increased elimination of the urobilin that had become stored in the liver as the result of a deficient function. Moreover, the urobilin content of the digestive tract increases and a reabsorption follows here, the urobilin passes the liver unchanged, enters the blood stream and then the urine, and increased urobilinuria results. However, in some cases the urobilinuria failed to appear. This occurred in cases in which there was a severe disturbance in the water economy. In some instances the water tolerance test had a surprising therapeutic effect in that the icterus disappeared quickly. However, this effect was largely dependent on the stage of the disease in which the water test was made. The phenomenon is probably related to the water exchange, for, if the latter was greatly impaired, the water tolerance test was even followed by a further exacerbation of the disorder.

**Treatment of Obesity by a Diet**—Hanssen cites studies by Hagedorn and others, which proved that obesity results from an abnormally increased transformation of carbohydrates into fat, owing to an anomaly of the metabolism. In the treatment of twenty-one obese patients the author took this origin of obesity into consideration in that he restricted the carbohydrate intake of the patients in order to prevent a surplus of carbohydrates being deposited as fat. To be sure, the amount of carbohydrates should be sufficient to insure combustion of fat without acidosis. The patients were given a diet that provided generous amounts of greens, some fruit, meat or fish in amounts of from 100 to 125 Gm, 100 Gm of bread, 65 Gm of cream, 65 Gm of butter, 35 Gm of cheese, two eggs and 25 Gm of olive oil. In the preparation of the foods the use of flour and sugar was avoided and substitutes were used instead. The daily food intake was approximately equal to 1,850 calories (71 Gm of protein, 117 Gm of fat and 112 Gm of carbohydrates). Exercises that might tire the patients were avoided, but care was taken that they got some fresh air every day. The author asserts that the average weekly loss of weight was 0.87 Kg. He compares these results with those obtained in other hospitals and finds that with his method the patients lose about the same amount of weight with an intake of 1,850 calories as is the case in another hospital in which the intake of patients under treatment for obesity is only 950 calories. In a third hospital in which the daily intake was only 765 calories, the loss in weight was somewhat greater. Whereas the diet prescribed by the author was rich in fat and relatively low in carbohydrates it was the opposite in the other hospitals. Besides effecting a reduction in weight with a relatively high caloric intake the author's diet has the added advantage that it is more readily adhered to after the patient has left the hospital. This is important since in a metabolic disorder such as obesity treatment must be continued. Examination of the author's patients from four to twenty months after they had been discharged from the hospital showed that the results were quite satisfactory.

## MODERN TRENDS IN SURGERY

J TATE MASON, MD

SEATTLE

The man who attempts to point out the trends in any particular human activity must to a certain extent assume the role of a prophet—and that is a delicate thing to do, for events are bound to take place relentlessly and with little regard for the words of the prophet. If he has been lucky in his forecasts he usually receives but little credit, but if he has been wrong he is not allowed to forget.

There are two methods which the prophet may use. The first, and the more reliable, is to foretell the future by extending the knowledge of the past. In this method, however, there are two possible weaknesses. Our prophet may have only a dim or distorted view of ancient knowledge and facts on which to base his forecasts, again, recent events which are to prove of great importance may be so close to him that he cannot see them and hence has not yet been able to acquire a proper perspective. Unless he has such a perspective and a good knowledge of the well blazed trails of today, he will not be successful in projecting his speculation into the future.

The second method is by pure speculation, dreaming and divination. All prophets should be dreamers, in science and the progress of science, however, dreams must become hypotheses these must be succeeded by theories, and the theories finally proved or refuted. The man who would dream dreams of the future in medicine and surgery can hope for nothing but the severest tests of his prognostications. Hence I will only mention this second method of prophecy and adopt the far safer effort of presenting the subject of modern trends in surgery by relying as far as possible on the facts that are known and the comparatively recent changes and experiences that can be observed.

### ECONOMIC AND SOCIAL TRENDS

Profound changes are taking place at present in our social, economic and political condition. Without doubt these changes must affect the medical profession as a whole. Many citizens seem to desire such a change in our status. I recognize this ferment but I regret it exceedingly. The problem for the physician is twofold. Not only must he consider his own personal professional status but it is also his responsibility to consider the welfare of the general mass of citizens. The average person has little conception of the latter

problem, having been much influenced by all sorts of propagandists without any idea of the dangers that would ensue from the adoption of various ill considered schemes.

The leaders of medical thought must give time and attention to these problems, they cannot be ignored. We should never refuse to consult with lay groups and should seek opportunities for such discussion whenever possible. Only by such consultation and advice can our profession act as a stabilizer at a time when so many unsound plans for changing the economic relations of patient and physician are being presented.

During the past few years, diminished income and economic distress have not been limited to manual workers or to salaried brain workers. The professions also have felt the pinch. After ignorance and greed, this stress of economic necessity saps the roots of medical ethics. Competition is keenest and most ruthless near the foot of the economic ladder. The evil of secret fee splitting has never been fully abated. Economic necessity tends to increase this pernicious practice. It is time to warn again and to point out again that secret fee splitting is still as dishonest, as antisocial, as subversive of morals and as great an abuse of the fine confidential relations existing between physician and patient as it ever was. The patient and his illnesses and his operations are not a commodity for sale and barter between physicians.

As in other affairs of life, the first responsibility rests with the individual physician. The next is with his country society, which has within its power the first disciplinary measures. The function of the central organization must be largely educational and its influence first of all moral.

### ELEVATION OF STANDARDS IN SURGERY

Pressing for solution as never before is the question as to who should be permitted to practice major surgery. The right to undertake a major surgical procedure should not be bestowed lightly. To be a surgeon is at once a great privilege and a great responsibility. The day of the self-made surgeon is or should be past. With rare exceptions only those able to show unusual qualifications and special and adequate training should be admitted to the group that might be called "master surgeons."

The teaching of medical schools and hospitals has raised the quality of our craft immensely. Even so many poorly qualified men aspire to be surgeons, and there is as yet no way to prevent their assumption of quality long before they are justified. Their legal right under our various state laws is unquestioned. Obviously, the further responsibility of improving the grade of surgeons and protecting the public is in the hands of the surgeons themselves. An impressive lesson as to what may be done can be found in the improvement

Address prepared by the President Elect of the American Medical Association for presentation before the opening general meeting at the Eighty-Seventh Annual Session, Kansas City, Mo., May 12, 1936.

of medical schools and the raising of the standards of general medical education which followed the work of the Council on Medical Education beginning in 1905.

The desirability of special training in surgery and the great necessity for it have been so obvious to instructors and students alike that great progress has been made already in the line of postgraduate teaching in hospital positions, fellowships and assistantships. The establishment of an examining body like the American Board of Surgery at present contemplated would, while giving recognition to those fully qualified, act at the same time as a deterrent to those not qualified.

I do not want it understood that I favor withholding adequate instruction in surgery in the colleges from those who do not aim to become master surgeons. Many such men in the past have given good service in the field of minor and emergency surgery and can be depended on in the future. Isolated communities and even the smaller cities are usually dependent on such men for the relief of surgical conditions arising in their practice. On the judgment of these men and their recognition of their own limitations much depends. I speak in praise and in behalf of these faithful servants of the people. I believe that most of the criticism already voiced applies not to them but rather to the overambitious man of the large and middle sized cities.

#### THE PAST AND THE PRESENT

The history of the medical past has been presented so frequently that I offer no apology for referring to it briefly. Little of importance was performed in surgery prior to the beginning of the nineteenth century. True, the treatment of wounds was practiced in crude fashion. The aphorisms of Hippocrates and the anatomic studies of Galen and later of Vesalius mark the really important achievements of early centuries.

Leaving out of consideration the advancement of medical science in general, the clinical observation of disease, the improvements in physical diagnosis and some knowledge of pathology, surgery continued a sterile field of endeavor. Not until the nineteenth century did the landmarks of importance from a surgeon's point of view become progressively more frequent. The abdomen was invaded by daring operators, mostly for ovarian tumors and in spite of the staggering mortality rate an increasing number of successful cases were reported.

The advent of general anesthesia in 1846 for the first time made possible the performance of operations of election. Even with this boon the dreaded sepsis stood like a black angel guarding the sacred precincts of the human body until the practical application of Lister's theories, based on Pasteur's discoveries, in 1866. The establishment of bacteriology as a sound and accepted science allowed a gradual but logical transition from the antiseptic to the aseptic era. Opportunity was now afforded the surgeon to observe pathologic conditions in the living body and stages of disease processes could be noted for the first time. New areas of the body were explored by the surgeon's knife and diseases never before considered surgical were treated successfully. Thus anesthesia, asepsis and bacteriology paved the approach to modern surgery.

In the last fifty years and especially since 1900, great strides have been made in the practice of the surgical art. By experimenting with new theories and by the trial and survival of some of these, the surgeon has been able to utilize discoveries in the other sciences and to make them an integral working part of the practice of his art.

The use of x-rays has added much not only to the diagnosis but also to the successful treatment of certain lesions. Somewhat more recently, radium has come to play an important part in treatment, especially of neoplastic conditions. The employment of electricity in the form of radiofrequency currents has made successful certain procedures previously impossible. By its use in the prevention of hemorrhage and the checking of the spread of malignant tumors, many lives have been saved.

Numerous instruments for diagnostic precision have been introduced during this latter period of surgical progress, including the cystoscope, bronchoscope, esophagoscope, proctoscope and lastly the gastroscope.

From the practice of his art came greater improvement in technical skill to the surgeon. Better lighting, better instruments, better organization of hospitals and their facilities, greater utilization of team work between the surgeon and allied specialties in diagnosis and treatment—all have contributed to the remarkable advances this branch of medicine has made in the past few decades. Improved hospital facilities, better nursing care and more pertinent methods of preoperative and postoperative care all have had their part in advancing surgery to its present status.

While all this improvement in technical skill was taking place, while the knowledge of the pathology of living tissues was being extended, while more and more refined and reliable mechanical aids were multiplying, a steady increase in the sciences of physiology and chemistry has supplied the surgeon of recent years with a new outlook on therapy. Surgery for fifty years had concerned itself chiefly with the correction of the mechanical defects of the body. Diseased organs had been removed, an obstructed bowel had been corrected, tumors had been destroyed—procedures made possible by the practical application of knowledge concerning the anatomy, chemistry and physiologic activity of the human body. But the surgeon of today is no longer content with these procedures. His desire is to restore if possible the whole organism to its physiologic harmony—reconstructive surgery. Vain hope, you may say, but still a goal devoutly to be sought!

One of the earliest efforts to influence physiologic balance by operations on the endocrine glands was the operation of hysterectomy and ovariectomy for hysteria and dementia—an effort soon found to be misdirected. Many of the ductless glands are now treated surgically with brilliant success. The results of thyroid surgery are too well known to need emphasis. Surgical treatment of dysfunctions of the adrenals, parathyroids and pancreas is being practiced rather widely, and many spectacular results are reported in the literature.

So, too, a better knowledge of the anatomy and the function of different parts of the nervous system has in recent years aided much in the diagnosis of abnormal conditions of that system and has permitted great advances in their surgical treatment. Surgical procedures for the relief of intractable pain have added immeasurably to the comfort of countless sufferers. Operations on the sympathetic nervous system, by increasing blood supply to certain parts, have saved many a person the loss of a useful bodily extremity. More recently, certain patients with hypertension have been assured much longer life and greater happiness by operations on the splanchnic nerves.

Thus the discovery of the three basic factors of anesthesia, asepsis and bacteriology, furthered by the development and application of anatomy, pathology,

chemistry and physiology, promoted rapid progress in surgery. We have been permitted to perform surgical procedures undreamed of before their discovery. We now successfully explore and treat surgical conditions of practically every portion of the body. The abdomen and even the chest and the intracranial cavity may be entered with impunity by competent surgeons. These procedures would have been declared impossible less than a hundred years ago. With our increasing knowledge and our improvement in technic, we are now in a transition era that is a transition from surgery as a mechanical correction of disorders of the body to surgery aimed at a restoration of normal bodily function. The surgeon of today is concerned not only with the eradication of the morbid process but also with the restoration of the body to the physiologic normal.

#### THE FUTURE

If I may now be permitted to project these past and present tendencies into the future, some foresight may be gained as to whether we are tending, in surgery specifically and perhaps in medicine generally. In this respect I have little sympathy for those who assert that no further improvement is to be expected in surgical technic. No less an authority than Billroth is credited with having made such a statement long ago. From time to time others equally respected have made similar remarks. We have seen how history has rapidly and consistently refuted their pessimistic prophecies. Progress in this element has continued with increasing rapidity. Technical skill will continue to be improved.

There is no limit to mechanical ingenuity in the production of new apparatus. New instruments will not only improve the technical skill but as diagnostic aids will enable the surgeon to determine and correct disorders of function possibly even before morbid processes develop. It is truly hoped that the latter state will be reached. Therein surgery will become a preventive measure, so to speak, as well as a curative agent. The trend of medicine generally is toward prevention. Surgery is and will continue keeping pace in this direction.

The far more numerous and better equipped investigators in all lines of scientific endeavor speak for more rapid progress in the near future than those of us who have observed the remarkable strides in the past quarter of a century can possibly conceive at this time. Anesthetics and the methods of their application are constantly being improved. It is not too much to expect that an ideal in this respect will soon be conceived and developed for us.

Greater team work between all the specialties in the medical art is confidently expected. Cooperation between the physiologist and the surgeon has already meant much to surgical progress as we have seen. This is true of the consultation between all the groups. More such cooperation cannot fail to further medical and surgical progress.

There is at present an increasing number of skilful well trained surgeons throughout the country. Where yesterday one or only a few were capable of some particular operation there are now dozens competent to undertake it. This wide diffusion of good surgeons is a most significant trend. No longer is it necessary for a patient to travel a long distance for special care. Each section of the country will have a selection of men competent in every special field of surgical endeavor. Naturally this will reflect to the betterment of medical care throughout the land.

Finally, may I plead that I am old enough and old fashioned enough in my point of view to speak a confident word for affability, kindness and a friendly personality on the part of the surgeon.

In the tremendous strides scientific medicine has made there has been overlooked one of our original and important aspects. That is the personal equation and the relation between doctor and patient. In the old days the instruction of a young medical student and doctor by a preceptor aided much in the development and furthering of this factor. The ripe years of experience of this older doctor gave much to the young man in the way of kindness and consideration and ability to be always ready to encourage the ill.

I fear that some of us became old in the practice of medicine before it was realized that the man of yesterday, with a limited amount of scientific knowledge, who in a kindly, knowing, sympathetic way placed his hand on the little girl's brow and said "Why, we will not let you suffer, you will be well in a few days" did more for her endocrine glands, that storehouse of chemical activities in her body to ward off and cure disease, than anything that has been discovered in recent years. So we must realize in the practice of medicine that fear, ambition, love, hatred, pleasing impressions cause a great and lasting influence on the greatest of all chemical laboratories that we carry in our bodies from birth until death. Medicine can go forward only by a blend of the heart with science, both of which are governed by the head. The young man who puts financial relations above everything else loses all the pleasures and fun of the game.

Certainly and thankfully we are not all made alike. I have seen the most skilled internist fail to detect some acute condition in which surgery was imperative. On the other hand, I have seen the surgeon with great experience overlook complications of the lungs, the liver or the kidneys. A friendly, thoughtful consideration of a patient's illness may have so many ramifications that he is always benefited by the advice of several men thinking along different lines. If we older men have been guilty in this respect, how much more are we obligated to teach our younger associates by precept and example so that they may avoid our errors.

#### CONCLUSION

My thesis then, is based on the fact that surgery as an art and a science is reaching a higher level of efficiency. This is the result both of teaching and of the untiring efforts of individual workers and cooperators. The present tendency is given to stressing the patient as a whole, the end in view being a restoration of physiologic harmony in the cure of his ailment. Thus the surgeon will come to treat and cure many diseases now considered incurable as well as many now considered nonsurgical in nature. Nor will he jealously insist on continuing the treatment of conditions which experience will prove from time to time, can be better managed by other than surgical means.

Further and narrower specialization may follow, though in this respect we seem now to be approaching a logical limit. Especially is this true when we consider the ideal that the patient must be treated as a personality rather than as the harbinger of a disease in which we happen to be interested.

Science like Time marches on. Progress beyond our wildest imaginings is coming. Surgery and medicine as a whole must and will continue in the vanguard.

1115 Terry Avenue.

EVALUATION OF ENDOCRINE THERAPY  
IN PRIMARY DYSMENORRHEA

AN ANALYSIS OF THIRTY-NINE CASES

S LEON ISRAEL, MD

PHILADELPHIA

This paper concerns that type of painful menstruation known as primary dysmenorrhea, for which there seems to be no adequate explanation. The clinical picture is well known. It is characterized by spasmodic pains beginning from thirty-six to forty-eight hours prior to or with the onset of the flow and subsiding during the first twenty-four hours of menstruation. Nausea and vomiting often accompany the attack. The very nature of the pain suggests its uterine origin. Such colic may arise from either heightened uterine contractions or painful spasm of the cervical sphincter. Evidence that both mechanisms may play a role has appeared recently in the literature.

However, if uterine colic per se is the cause of the pain, the primary cause of the disorder is still hypothetical. Some of the theoretical explanations are plausible, yet not one has attained universal acceptance, because of insufficient proof. The manifold forms of treatment that have been hopefully proposed, enthusiastically applied and regretfully discarded serve to emphasize the lack of knowledge of the etiology of primary dysmenorrhea. Each form of treatment is based on a different conception of the etiology of the malady.

THEORIES CONCERNING THE ETIOLOGY OF  
PRIMARY DYSMENORRHEA

In any study of primary dysmenorrhea, one must consider the constitutional and psychic background of the individual patient. The so-called constitutional inferior or the hypersensitive type (Libman) has a definitely increased pain reaction which may color the symptomatology and alter its clinical evaluation. Novak and Harnik<sup>1</sup> stress the importance of psychic trauma as an etiologic factor and maintain that psychotherapy relieves a large number of patients suffering from primary dysmenorrhea. However, neither a high degree of sensitivity to pain nor an apprehensive emotional state can possibly be the sole cause of any instance of primary dysmenorrhea. Perhaps the most important role played by the psychic element in this disease is that of complicating the proper evaluation of any therapeutic measure employed.

A neurogenic basis for primary dysmenorrhea has been advanced by some who ascribe the etiology to an abnormal reactivity of the cervical nerves. That nerve irritability or vagotonic spasm of the circular musculature of the isthmus may be a factor is favored by reports of relief through the use premenstrually of antispasmodics such as atropine,<sup>2</sup> benzyl benzoate,<sup>3</sup> and calcium.<sup>4</sup> A successful form of neurosurgical therapy, resection of the superior hypogastric plexus (presacral

nerve), has been evolved.<sup>5</sup> That a full measure of relief follows such nerve resection is not surprising, since the pain-bearing fibers are severed. However, it is a relatively heroic procedure and should be reserved as a last resort in the treatment of primary dysmenorrhea. Others liken the disease to herpes zoster, regarding the ganglions of Frankenhauser as the primary seat of disease and the pain as an expression of secondary neuralgia. Keiffer,<sup>6</sup> basing his theory on dissections of the pheochrom system of the uterus and the fact that stimulation of the internal os causes pain, uterine contractions and cervical spasm, attributes sphincteric powers to the cervical tissue. He looks on the cervix as a sphincter with its "tonus" governed by a reflex arc through the lumbar cord and cervical ganglions. Thus, an abnormal state of the cervical ganglions may be the immediate cause of the spasmodic pain. This hypothesis finds support in the work of Bloss<sup>7</sup> and Kennedy.<sup>8</sup> Bloss cured more than 90 per cent of dysmenorrhoeic patients whose cervical ganglions were injected with 70 per cent alcohol. Kennedy has offered experimental data which support the view that estrogenic substance not only stimulates growth and vascularity of the lower genital tract but also exerts a trophic influence on the cervical ganglions. In his study of the plexus of Frankenhauser following castration, Kennedy<sup>8</sup> noted degeneration of the ganglion cells characterized by a decrease in the amount of Nissl substance and a diminished number of pheochrom cells. By the administration of estrogenic principle to castrated animals, Kennedy was able to reverse these changes, the ganglion cells becoming normal. Kennedy<sup>9</sup> further ascribes the therapeutic effectiveness of estrogenic substance in primary dysmenorrhea to its ability to restore the atrophic ganglion cells to normal, relieving both trophic hypoplasia and arrhythmic sphincter action of the cervix. Reports of relief of primary dysmenorrhea by the administration of estrogenic substances fairly abound in recent literature.<sup>10</sup> In my opinion, many of the reports err in describing the temporary relief of pain as a "cure."

Because dysmenorrhoeic patients usually, if not invariably, present other evidences of marked instability of the autonomic nervous system such as visceroptosis, gastro-intestinal spasticity and irritability of the bladder, primary dysmenorrhea must be viewed as being a local manifestation of a constitutional disease. In fact, Dutta,<sup>11</sup> Smith<sup>12</sup> and Cooke<sup>13</sup> have recently suggested that primary dysmenorrhea may be the expression of an allergic state. They found unusual sensitivity to

certain foods or inhalants in most of their patients and offered desensitization treatment as a remedial agent in primary dysmenorrhea. This phase of the subject requires further investigation. Another debatable explanation is given by Whitehouse,<sup>14</sup> who attempts to explain all primary dysmenorrheas on the basis of membranous dysmenorrhea. He claims to have found pieces of hyperplastic endometrium in the menstrual discharges of fifty patients with primary dysmenorrhea and concludes that the expulsion of the hyperplastic endometrium gives rise to pain. The obvious question arises, Why is there an absence of dysmenorrhea in a large number of women with hyperplasia of the endometrium? Moreover, premenstrual endometriums of patients suffering from primary dysmenorrhea are usually in a normal secretory phase, which is a finding incompatible with the existence of endometrial hyperplasia.

The oldest explanation of the origin of primary dysmenorrhea is the one ascribing the pain to mechanical obstruction of the cervical canal. Theoretically, such an obstruction would cause retention of discharges and distention (pressure) pain. Fifty years ago it was inconceivable that there could be a cause for primary dysmenorrhea other than an obstruction caused by congenital or acquired cervical stenosis, pathologic ante-flexion of the uterus, or cervical myomas. Thus, the operation of cervical dissection, the use of the stem pessary and the application of the metronorkter enjoyed great popularity. However, it became apparent that not all patients with primary dysmenorrhea present anatomic obstructions and that many patients with acutely inflexed uteri are entirely free from menstrual pain. Eliminating the few patients with primary dysmenorrhea who present real cervical obstruction and who, accurately speaking, do not belong in the category of primary dysmenorrhea, one cannot deny that cervical dilation alone frequently relieves the pain. However, this fact does not prove the validity of the obstructive theory. In view of the newer knowledge of cervical function<sup>6</sup> and the trophic purposes of the cervical nerves,<sup>8</sup> the relief of primary dysmenorrhea following cervical dilation may be credited to a stimulative effect on the ovaries.<sup>15</sup> Such a result would be analogous to the ovarian reaction produced by mechanical or electrical stimulation of the cervix in experimental animals (pseudopregnancy).

Almost as time honored an explanation of the cause of primary dysmenorrhea as is the obstructive theory is that of uterine hypoplasia first propounded by Schultz<sup>16</sup> in 1903. The hypothesis suggests that primary dysmenorrhea is caused by stagnation of blood in the uterine sinuses and subsequent pressure pain because of insufficient musculature in an underdeveloped uterus. The most important argument against this theory is the fact that many women with the pituitary type of uterine hypoplasia are free from dysmenorrhea, whereas women with uterine hypoplasia of the primary ovarian type, characterized by a superlatively feminine appearance, gastro-intestinal irritability and emotional disturbances, have a high incidence of pri-

mary dysmenorrhea.<sup>17</sup> These facts and the additional observation that the uteri of patients with primary dysmenorrhea are often normal in size and consistency serve to emphasize the obvious fallacy in regarding hypoplasia as the sole cause of primary dysmenorrhea. However, the hypothesis of Schultz and the known ability of the ovarian follicular hormone, the estrogenic principle, to induce growth and vascularity of the lower genital tract (including the cervix uteri) form a theoretical background for the use of estrogenic substances in the treatment of primary dysmenorrhea.

Following the researches of Reynolds,<sup>18</sup> an endocrinopathic etiology for primary dysmenorrhea was propounded.<sup>19</sup> By means of an ingenious uterine fistula in an unanesthetized rabbit, Reynolds found that the normal uterine contractions disappear following castration, that administration of estrogenic substance restores them to renewed vigor and that the contractions produced by estrogenic substance are easily abolished through injections of corpus luteum hormone, progesterin, or the gonadotropic principle in the urine of pregnant women. Thus, it was shown that the gonadotropic substance present in the urine of pregnant women simulates progesterin in its quieting action on uterine muscle. More remarkable was Reynolds' observation that gonadotropic substance exerts its inhibitory effect on uterine contractions induced by estrogenic substance in the presence or absence of the ovaries, suggesting a direct uterine effect. Morgan<sup>20</sup> confirmed the work of Reynolds in the intact animal but found no quieting effect of gonadotropic substance on the uterine muscle in castrated animals. Thus, it was established that the excitant and the inhibitor of uterine contractions are ovarian follicular hormone and corpus luteum principle, respectively. These observations led Novak and Reynolds<sup>21</sup> to attribute primary dysmenorrhea to a premenstrual imbalance of the two ovarian hormones controlling uterine contractions, either an excess of estrogenic substance or a deficiency of the corpus luteum principle. Under such an abnormal endocrine influence the endometriums of dysmenorrhic women should invariably show a deficiency or a total absence of the secretory phase. That this is usually not the case is shown by a study<sup>22</sup> of the premenstrual endometriums in twenty women with primary dysmenorrhea fourteen of whom showed normal secretory endometriums (progesterin phase).

The use of corpus luteum substance in the treatment of primary dysmenorrhea was first recommended by Novak and Reynolds<sup>21</sup> on the strength of their theory. In the absence of an adequate commercial supply of the principle and in view of Reynolds' observations of the direct uterine effect of gonadotropic substance from the urine of pregnancy, the latter was suggested as a likely substitute. Recently, Witherspoon<sup>23</sup> and Browne<sup>24</sup> have reported on relief of dysmenorrhea with the use of urinary gonadotropic substance.

## RESULTS OF ORGANO THERAPY

As previously mentioned, two endocrine substances (estrogenic substance and corpus luteum principle) have been advocated for the treatment of primary dysmenorrhea. Both forms of organotherapy are theoretically convincing. The corpus luteum substance (progestin) and its substitute, urinary gonadotropic substance, reduce the sensitivity of uterine musculature, but at best the effect would be purely temporary. The estrogenic principle supposedly removes painful cervical spasm either by inducing growth and vascularity of the hypoplastic cervix (Schultz) or by correcting disturbances of the cervical ganglions (Kennedy).

Bearing all this in mind, my associates and I have employed both modes of organotherapy in thirty-nine patients with primary dysmenorrhea. The duration of the dysmenorrhea prior to treatment was more than eighteen months in each instance, and the average duration was four years. The pelvic organs, as far as one could determine by examination were normal with the exception of palpable uterine hypoplasia in some

*Observations on Endocrine Therapy in Thirty-Nine Patients With Severe Primary Dysmenorrhea*

Form of Endocrine Therapy	Dose and Average Duration of Treatment	Number of Patients	Results			
			Cured	Temporary Relief	Substitutive Relief	Failure
Urinary gonadotropic principle (antuitrin-S)	200 rat units every other day for from 2 to 3 months	10	1	0	3	6
Estrogenic principle (emmenin)	1 tablespoonful (70 day oral units) three times a day for from 3 to 5 months	10	1	0	2	7
Estrogenic principle (progynon)	600 rat units three times a day for from 3 to 4 months	6	0	0	1	5
Estrogenic principle (progynon-B)	5 000 to 10 000 rat units every fourth day for from 3 to 4 months	13	0	4	6	3
Totals		39	2	4	12	21

instances. The ages of the patients ranged from 17 to 28 years. Thirty of the thirty-nine patients were nulliparas, and twenty-six of the group were sterile or had menstrual disorders (oligomenorrhea or hypomenorrhea). Ten were treated with a commercial gonadotropic substance obtained from pregnancy urine (antuitrin-S). Sixteen received small, oral doses of estrogenic substances (as liquid emmenin or progynon tablets). Thirteen were given large hypodermic doses of estrogenic principle in the form of hydroxyestrin benzoate (progynon-B). The substances were administered during the entire menstrual cycles for periods averaging three months. The results of treatment, as shown in the accompanying table, were tabulated as follows: "cured," when the patient remained well for a year or more after withdrawal of treatment, "temporary relief," when the patient was free from pain during the course of treatment and for from two to four months afterward, "substitutive relief," when the patient was entirely free from dysmenorrhea only while receiving treatment and in whom there was an immediate recurrence of dysmenorrhea on withdrawal of therapy, and "failure" when the patient obtained no relief from the treatment.

**Urinary Gonadotropic Substance**—Ten of the thirty-nine patients received antuitrin-S subcutaneously every other day in doses of 200 rat units (2 cc) for

periods of from two to three months. Four patients of this group experienced relief from dysmenorrhea; one has remained well for a period of fourteen months after withdrawal of treatment, and the other three had painless periods during the course of treatment only. The remaining six patients of this group were unaffected by the treatment. There were no constitutional effects noted as a result of the administration of the urinary gonadotropic substance. However, some of the patients, at some time during the course of treatment, complained of pain, redness and swelling at the site of injection. Such local reactions ordinarily subsided within twenty-four hours.

**Small Oral Doses of Estrogenic Principle**—Sixteen of the thirty-nine patients were given small oral doses of estrogenic substances. Ten of the sixteen patients received a complex containing trihydroxyestrin (emmenin) in doses of 1 tablespoonful (approximately equivalent to 75 day-oral units) three times daily for periods averaging four months. Three patients of the ten so treated were relieved of pain; one has remained symptom free for one year following the course of treatment, and the other two were relieved only while the emmenin was administered. The dysmenorrhea of the remaining seven patients who received emmenin was unaffected by the therapy. Six of the sixteen patients were given a commercial preparation containing keto-hydroxyestrin and trihydroxyestrin (progynon tablets) in doses of 600 rat units three times daily for periods averaging three months. One patient was free from dysmenorrhea while under treatment, the remaining five patients were unrelieved. There were no constitutional effects noted as a result of these small oral doses of estrogenic principle.

**Large Doses of Estrogenic Substance**—Thirteen of the thirty-nine patients were treated with estrogenic substance in the form of hydroxyestrin benzoate (progynon-B) administered intramuscularly in doses of 5,000 to 10,000 rat units every fourth day for from three to four months. Of this group, six were entirely free from pain only while the substance was administered and four remained symptom free from two to four months following withdrawal of treatment. The remaining three patients of this group were unaffected by the therapy.

It is interesting to note the absence of any constitutional effects, aside from a temporary disturbance of the menstrual cycles in several patients, following the administration of such massive doses of estrogenic substance (from 200,000 to 320,000 rat units during three to four months). The fact that such large doses of estrogenic principle are well tolerated and cause no constitutional disturbances in the human being was previously established by Mazer, Meranze and Israel.<sup>24</sup> Three of the eight regularly menstruating women in this group of thirteen patients experienced a delay of from one to three weeks in the onset of a single period while under treatment, but menstruation was regular subsequent to the withdrawal of treatment. This temporary menstrual disturbance—a delay of a single period and the establishment of a new date of onset of the subsequently regular cycles (irrespective of continued therapy)—was likewise noted in six of seventeen regularly menstruating women subjected to similar treatment for other conditions.<sup>24</sup> Kurzrok and his asso-

ciates<sup>25</sup> observed a similar, temporary disturbance of the menstrual cycles of women under treatment with large doses of estrogenic substance

## SUMMARY

1 From a review of the literature, primary dysmenorrhea is shown to be a disease of conflicting theories. No satisfactory explanation of its etiology exists.

2 Two forms of endocrine therapy have been proposed for primary dysmenorrhea, estrogenic substance and (in the absence of progestin commercially) urinary gonadotropic substance. As shown in the present study of thirty-nine patients, both forms of organotherapy are disappointing.

3 Urinary gonadotropic substance (antuitrin-S) administered to ten patients cured one and temporarily relieved three of dysmenorrhea.

4 Estrogenic principle, given orally in small doses (emmenin liquid or progynon tablets) to sixteen patients, cured one and afforded temporary relief to three of the patients.

5 Estrogenic substance, given hypodermically in large doses (progynon-B) to thirteen patients, produced no permanent results. Ten patients were temporarily relieved and three were totally unaffected by the therapy.

EDWIN J. KEPLER, M.D.

AND

RUSSELL M. WILDER, M.D.

ROCHESTER, MINN.

Two papers that appeared in a recent issue of *THE JOURNAL*, one by Hagedorn and his associates<sup>1</sup> of the Steno Memorial Institute of Copenhagen the other by Root, White, Marble and Stotz<sup>2</sup> of the New England Deaconess Hospital, have aroused widespread interest in insulin protamine compound. This new remedy for diabetes already has been distributed to a good many physicians and soon will be on the market and available to all. For this reason it seems to be desirable to make available to others the experience that we have had with it.

The Danish investigators found that insulin precipitated from solutions of insulin hydrochloride with monoprotonic compounds and suitably buffered, was relatively insoluble in tissue fluids so that its absorption was delayed and its action correspondingly prolonged. They demonstrated that such insulin facilitated the management of cases of severe diabetes as indicated by smaller fluctuations of the sugar in the blood. The best results usually were obtained by giving the patient "ordinary" insulin in the morning and insulin protamine compound in the evening or with two doses of insulin protamine compound a day. A few cases were treated

effectively with a single dose. In many cases a smaller dose of insulin protamine compound was required than the dose of ordinary insulin used before. A more detailed report of the clinical studies in the Steno Institute is contained in a monograph by Krarup.<sup>3</sup>

The Boston physicians were able to confirm the Danish observations. Wide fluctuations in the levels of the blood sugar were less frequent and hypoglycemic reactions were largely avoided. At the time of writing, their experience was limited to fifteen cases, but since then they have treated more than eighty patients, with results that are pleasing.<sup>4</sup> In their paper they commented on certain inconveniences. The compound is not indefinitely stable and the protamine must be added to a given vial of insulin only as the insulin is needed for use within the ensuing few days. Since then they have found that it is stable for four weeks. Furthermore, the addition of the protamine, which they thought must be made with a dry, cool syringe, can now be made with a syringe which is wet with ethyl alcohol in which it has been kept for the purpose of insuring its sterility. The schedule of procedure in the Deaconess Hospital has been like that of Hagedorn, namely, the use in most cases of regular insulin in the morning and of the new preparation for the evening injection.

Our experience with insulin protamine compound (insulin-P<sup>5</sup>) is brief but intensive.<sup>6</sup> Only twenty patients have been treated at the time of this writing, but nearly all of them have been the subjects of prolonged observations in the hospital with trials of various schedules of administration of insulin. In the course of the observations more than 2,000 analyses have been made of the content of blood sugar, using in each instance capillary blood obtained from a finger or a lobe of an ear and subjected to the micro-analysis, for dextrose, of Folin. Ten of the twenty patients represented cases in which control of glycosuria and attacks of acidosis was exceedingly difficult or impossible with insulin-R. We grade such cases 4+. Seven other patients had diabetes of such severity that three or four injections daily and a total dose of more than 50 units of insulin-R had been required to maintain control. The remaining patients required from 30 to 50 units daily in two or three divided doses. Ten of the patients were children. The duration of the disease in every case was more than three years and in many cases the patient had been under our care for ten years or more. In most cases, with the use of a single administration of insulin we have been able to attain better control of glycosuria and a more stable level of the blood sugar than previously had been possible with multiple doses of insulin-R. Frequently, as will be described, this administration has consisted of the injection simultaneously but in separate sites, of insulin-P and insulin-R.

## TIME OF INJECTION OF INSULIN

We were led to the single intratumal administration of insulin-P, with or without supplementary insulin-R, by what appeared to be conclusive evidence that the action of insulin-P was prolonged for more than twenty-four hours and the observation that much of

<sup>3</sup> Krarup, N. B. Clinical Investigations into the Action of Protamine Insulin. Copenhagen, C. F. C. Gad, 1935.

<sup>4</sup> Root, H. I. Personal communication to the authors.

<sup>5</sup> For convenience of expression we have adopted the designation insulin-P for the regular water soluble insulin hydrochloride and insulin-R for insulin protamine compound.

<sup>6</sup> A small supply of insulin protamine compound was received from Dr. Hagedorn early in January. For this we wish to express our appreciation. Soon thereafter and regularly since then other material has come from the Eli Lilly Company through the courtesy of Dr. C. H. A. Clow. The observations to be reported were made with the preparation of the Eli Lilly Company.

<sup>2</sup> Root, H. I., White, I. R., Marble, Alexander and Stotz, F. H. Clinical Experience with Protamine Insulin. *J. A. M. A.* 106: 180-183 (Jan. 18) 1936.

the effectiveness of insulin-P remains in abeyance until after the lapse of from four to six hours. An observation which reveals the absence of a quick effect, and also shows the late action, is recorded graphically in chart 1.

A woman, aged 49, who had diabetes of nine years' duration, had been under intermittent treatment by us since 1927 and was customarily receiving 55 units of insulin-R daily and a diet containing 111 Gm of carbohydrate, 65 Gm of protein, and 127 Gm of fat.

Chart 1—Effect of 35 units of regular insulin compared to that of the same dose of insulin protamine compound. Breakfasts containing 38 Gm of carbohydrate was served on these days but no other meals. Symptoms of severe acidosis developed the morning following the administration of the regular insulin; no such symptoms the morning following the administration of insulin protamine compound. In the charts the shaded columns represent ordinary insulin; the black columns insulin protamine compound.

was vomiting, with abdominal pain and air hunger. The carbon dioxide combining power of the blood plasma was 28 volumes per cent, and the urine for this period of twenty-four hours contained 41 Gm of dextrose and much acetone and diacetic acid. This, it should be emphasized, occurred after a single injection of regular insulin insulin-R.

Treatment was instituted. It involved injecting 1,000 cc of physiologic solution of sodium chloride and giving repeated

Chart 2—Improved control of glycosuria with insulin protamine compound supplemented with a small dose of regular insulin. The letter R enclosed in a circle in this and other charts indicates reaction. In no case were the reactions severe. The full effectiveness of insulin protamine compound is not apparent until the third day after the administration of the given dose.

does of insulin-R. Three days later February 5 the acidosis in the meantime having been brought under control a similar study was made after injecting insulin-P in a dose of 35 units. The blood sugar stood at 400 mg per hundred cubic centimeters about the same level as before. The breakfast was served and the noon and evening meals were withheld as they had been before. No more insulin was given. The blood

sugar increased after breakfast to a peak of 530 mg per hundred cubic centimeters, reached at 10 a.m. It then fell gradually and steadily until, at 2 a.m., February 6, it stood at 160. At 7 a.m., February 6, it was 270. The urine for the twenty-four hour period contained more sugar than it had in the experiment with insulin-R, but the single specimen of the morning of February 6 contained only a trace of sugar, and the patient, instead of presenting a condition verging on coma, was perfectly comfortable, free from any signs of acidosis, with no acetone to be smelled on the breath, and none demonstrable in the urine. Chart 1 shows the observation of February 2 on the left and the important data of another observation like that of February 5 on the right. This time a single injection of 35 units of insulin-P, with breakfast, but not followed by other meals or more insulin, left the blood sugar at 145 mg per hundred cubic centimeters the succeeding morning.

Insulin-P, when given before breakfast to a patient receiving the three meals of his regular diet, may not control the elevating effect of breakfast on the blood sugar. By noon however its action is apparent. Furthermore, when the case finally is brought under complete control, so that the blood sugar before breakfast is normal, the rise following breakfast frequently

Chart 3—Poor control of glycemic level in a case with insulin used in multiple doses compared to satisfactory control after February 15 with a single dose of insulin protamine compound supplemented with a small dose of regular insulin.

has not been enough to provoke glycosuria. In cases in which glycosuria occurs after breakfast, and in many cases for the first few days after beginning the use of insulin-P we have administered a small dose of insulin-R as a supplement to insulin-P. Usually the insulin-R has been given at the same time, that is, in the morning. The insulin-R must be injected in a separate site, if it is mixed with insulin-P it is combined by the excess of protamine in the insulin-P and its quick effect is lost.

In cases of severest diabetes, large doses of insulin have been required. For instance, in one case 70 units of insulin-P and 30 units of insulin-R were given before breakfast. The blood sugar at the time of the injection was 90 mg per hundred cubic centimeters at 11 a.m., 70, at 2 p.m. 160 at 5 p.m. 100 and at 10 p.m. 75. The following morning it was 65 mg per hundred cubic centimeters. This dose was excessive, it was diminished the following day.

Illustrations of satisfactory control of the blood sugar level with morning injections of insulin-P supplemented with a small dose of insulin-R are given in charts 2 and 3. The blood sugar values in a case in which, after four days, only insulin-P was used are shown in chart 4. It should be emphasized that although single, large

doses of insulin-P apparently are safe in severe cases, when the patient takes his food, it is very important, if he receives such doses, that he get the food. Should a patient refuse his food, after receiving an injection before breakfast, periodic administrations of dextrose would be indicated for the remainder of the ensuing twenty-four hours.

In order to obtain more information about this we gave 50 units of insulin-P in one case, withheld food and followed the blood sugar level by examination at frequent intervals (chart 5).

The patient previously had been brought under good control with single morning injections of 60 units of insulin-P. It happened that the blood sugar on the morning of this investigation was higher than it had been on previous mornings. Beginning at 286 mg per hundred cubic centimeters it fell slowly not reaching a level below 70 mg per hundred cubic centimeters until 5 p. m. By 10 p. m. it was 45 mg per hundred cubic centimeters and it stayed close to this level until the following morning. Fasting was continued and although no more insulin was given the blood sugar remained below 50 mg per hundred cubic centimeters in this the second day until 9 p. m., thirty-eight hours after the injection of insulin. At 9 p. m. of the second day the very low value of 25 mg per hundred cubic centimeters was encountered and, fearing possible injury to the patient from such severe and long continued hypoglycemia

three meals a day from the general kitchen. The only restricted foods were candy and raw sugar. The patient was severely diabetic but her management had been satisfactory with a diet containing 167 Gm of carbohydrate and a single matutinal dose of 50 units of insulin-P a day. When the "general diet" was prescribed, the dose of insulin-P was increased to 60 units. The result is shown in chart 6. For the first two days glycosuria occurred but later the control was excellent. This probably is not the way to treat diabetes even with insulin-P. Undoubtedly other patients who have more severe forms of the disease would not have done so well with such an irregular arrangement. Yet it does suggest that in many cases insulin-P may permit less rigidity in dietary management than heretofore has been necessary to secure satisfactory therapeutic effects.

Chart 5—Effect of a single large dose of insulin protamine compound when food was withheld. Hypoglycemia existed from the ninth to the thirty-ninth hour after the injection of this dose of insulin. It was then corrected by administering food.

#### ESTIMATING THE DOSE OF INSULIN-P

For patients who previously are under control or nearly so, with divided doses of insulin-R, we have been making an immediate substitution of one dose of insulin-P, with or without a small dose of insulin-R, for the previous total daily divided dosage of insulin-R (chart 4). No untoward effect has been observed, probably because the final effectiveness of the insulin-P is delayed even beyond the day of its administration. If no insulin-R is used, a fairly intense glycosuria may occur for the first few days. This has not been accompanied by serious ketonuria. Gradually the daily excretions of dextrose diminish and usually by the sixth or seventh day control is as good as or better than it was before with multiple injections of insulin-R. At some

Chart 4—Satisfactory control of glycemic level with single doses of insulin protamine compound given before breakfast.

we supplied food until sugar appeared in the urine. No alarming symptoms accompanied this hypoglycemia although periodically, but not continuously after 7 p. m. the first day the patient complained of nausea, weakness, nervousness and headache. In the evening of the second day there was increased nervousness leading to restlessness and some confusion. Exaggeration of tendon and diminution of cutaneous reflexes were found at this time. They had been normal before. Amnesia did not develop.

#### THE DIET

Because of the better control of the level of the blood sugar with insulin-P we recently have deviated from our usual procedure and have provided diets that contained from 160 to 170 Gm of carbohydrate. Their content of protein has been about 70 Gm, and enough fat has been added to bring the calories to a number that would represent 50 per cent more calories than the patient would expend at rest. The diet has been given in three meals and recently the carbohydrate has been apportioned approximately on a 20-40-40 basis, in other words, the breakfast provides only about half as much dextrose as do the later meals. The slow development of the maximal effectiveness of insulin-P makes this desirable. Hagedorn giving insulin protamine compound in the evening divided his diet so that about 40 per cent of the carbohydrate came in the breakfast, 40 per cent in the lunch and 20 per cent in the supper.

In one case we departed radically from our usual dietetic procedure and permitted the patient to have

Chart 6—Satisfactory control of glycemic level in a case of diabetes with single doses of insulin protamine compound given before breakfast and a general diet.

time later smaller doses of insulin-P may suffice so that an actual saving of insulin is accomplished. Our results to date do not permit definite conclusions as to the amount of saving possible although in some cases the saving in unitage has amounted to more than 30 per cent. If the original dose of insulin-P is supplemented by small doses of insulin-R, the initial period of intense glycosuria is shortened or may be avoided.

When using insulin-P, one is aiming about seventy-two hours ahead. Changes in the dose of insulin-P in either direction are not accurately reflected in the level of the blood sugar on the day the change is made. This is illustrated in charts 7 and 8. The patient the curve of whose blood sugar is shown in chart 7 reacted to the point of amnesia on the morning of March 8, although three of the four single specimens of urine on the day before had contained sugar. Therefore the

Chart 7—When insulin protamine compound is used the level of blood sugar before breakfast is the best index of the dose required. Hyperglycemia and glycosuria occurring later in the day do not preclude the possibility of reaction the following morning.

test for sugar of the morning urine is probably a more reliable simple index of the requirement of insulin-P than are the tests made during the day. The following working rule has been adopted recently. When the tests of the morning urine have shown no sugar for three days in succession and if reactions have occurred at night or in the early morning, the dose of insulin-P should be lowered. When the morning tests show sugar for three days in succession, the dose of insulin-P should be raised. Increasing or decreasing the dose by more than 5 units seldom is desirable.

It seems probable ultimately that the patient will take a basic dose of insulin-P, suited to his tolerance and usual activities, that this dose will be changed infrequently, and that small doses of insulin-R will be added as required to prevent occasional glycosuria provoked by infection or other causes. Occasionally patients who are being well controlled with insulin-P may, for a day or two, excrete a good deal of sugar without any apparent reason. This seems to have no bad effect and may be ignored unless it continues for more than two days. If it persists, either a few small supplementary doses of insulin-R may suffice for its control or, if the tests of urine passed before breakfast are positive, the dose of insulin-P should be increased.

Thus far we have not had experience in estimating the dose of insulin-P for patients who previously have not been treated with insulin-R. The slow acting nature of insulin-P would seem to make it unsuitable for the treatment of acidosis and possibly in most cases treatment will be begun with insulin-R and changed later to insulin-P.

7. More recently we have observed that insulin protamine compound is helpful in the management of diabetic acidosis. Thus to two patients admitted to the hospital with threatening coma the compound was given in a single dose of 30 units and the patients then were treated with regular insulin in the conventional manner. Less frequent doses of regular insulin subsequently were required than usually are necessary for the treatment of acidosis. The duration of effectiveness of a dose of regular insulin apparently is shortened by acidosis and unless regular insulin is given in frequently repeated doses intervals occur when the patient may be without the benefit of any insulin. Insulin protamine compound administered at the beginning of such treatment seems to tide over the intervals and to insure a continuous insulin effect. Similarly in cases complicated by acute infections which also shorten the duration of effectiveness of insulin protamine compound has been helpful—no to replace regular insulin but as an adjunct to it to insure continuous insulin activity.

## SITE OF INJECTION

Changing the site of injection or giving multiple injections simultaneously seems not to influence the effectiveness or speed of action of insulin-P. Our observations on this point are limited to one case. But with this patient, giving 65 units in one subcutaneous depot had the same effect as giving the same total dosage in four separate depots. Likewise no difference could be observed in the effect obtained, in one case, when the insulin was injected intramuscularly.

## REACTIONS

Partly because of an early ambition to maintain the sugar in the blood near normal levels at all times, and partly because of early unfamiliarity with the continued action of insulin-P remote from the time of injection, we have had occasion to observe rather numerous reactions, particularly in our earlier cases. These reactions have never been very severe, nor, in the cases treated in a routine manner, have we encountered any extreme degrees of hypoglycemia.

The reactions with insulin-P characteristically are less violent than those following the use of insulin-R. This probably is because the rate of decline of the blood sugar is so much more gradual. Their onset is insidious, but once developed they are more persistent and more likely to recur after treatment. Frequently we have heard patients complain of "feeling all tired out" or of having a vague sense of unrest or nervousness for which they can offer no explanation. There is less tendency to perspire than in the reaction from insulin-R. Paresthesia and anesthesia are experienced, particularly numbness about the mouth, such as is seen frequently in reactions to insulin-R. One patient spoke of tingling of the fingers and another said he felt dead from the hips down. Amblyopia and diplopia are common complaints. A dull headache may persist after

Chart 8—Loss of satisfactory control of glycemia from inadequate dose of insulin protamine compound. The inadequacy of the dose is not apparent until the third day. Previously satisfactory control had been secured with 60 units of insulin protamine compound supplemented with 5 units of regular insulin.

other symptoms have subsided. Amnesia characterizes reactions of greater severity. Convulsions have not been observed except in one case, the patient is a child who twice has had slight intermittent convulsive movements of the arms and legs in the early morning hours. In three cases nausea has accompanied the reaction but has disappeared on the administration of food.

The time of occurrence of reaction, after single morning doses of insulin-P, has been remote from a preceding meal. Some reactions have been at night.

These reactions were mild, but we feel that the dangers of even mild reactions of long duration should be emphasized.

The relief of the symptoms of reaction by the administration of small doses of sugar (from 5 to 10 Gm) may be temporary. Such a dose has been adequate only when the time until the next meal has been brief. Reactions occurring in the evening have been combated effectively by giving repeated small doses of sugar or, better, by giving some form of carbohydrate, such as crackers and milk, with a longer period of absorption.

#### SUBJECTIVE IMPROVEMENT

Several patients have commented that they felt fitter after starting their treatment with insulin-P. They arise from the night's sleep feeling more alert and they are stronger. They appear more alert. This has been noted especially in those cases graded 4+, in which previously, with insulin-R, satisfactory control had not been obtainable.

#### PRECAUTIONS

While our experience has led us to the belief that better therapeutic results are obtainable with insulin-P than were formerly obtained, it is not to be supposed that the new remedy can be used safely unless precautions are exercised. The right dose must be chosen and the diet ought to be supervised. This potent drug has a complicated action and it should not be dispensed casually. It offers a further challenge to the intelligence of the medical profession. If it is used unwisely, imperfect results or bad reactions may discredit it. Certainly at first no one should use it unless he places his patient in a hospital where continuous supervision can be maintained and facilities are available for testing the sugar in the blood. The patients must have been fully instructed regarding their diet, the recognition of the prodromes of reaction and the niceties of planning the size of their injections, before it will be safe for them to use this treatment in their homes.

#### SUMMARY

The immediate effect of insulin-P (insulin protamine compound) is much less than that of insulin-R (regular insulin). When the former is used alone and given as a single dose before breakfast the meals of the first few days provoke glycosuria but when the dose is properly adjusted the level of the blood sugar on successive mornings decreases progressively and the elevating effect of meals diminishes until by the end of from four to six days, a normal level of blood sugar may be attained even in cases of severest diabetes.

Supplementing insulin-P with small doses of insulin-R will shorten the period of obtaining control. Insulin-R should not be mixed in the same syringe or injected into the same site with insulin-P. It has not been necessary to continue the supplementary use of insulin-R after the first few days in the milder cases but probably in many cases such supplementary use of insulin-R will be desirable, especially in emergencies. Until more experience has been obtained it would appear that insulin-R will be the insulin of choice when quick action is desirable as in the treatment of acidosis.

Although insulin-P in many cases makes possible effective management of diabetes with only one administration of insulin a day and with less insistence on rigid control of the diet its careless use or disregard of the diet is attended with danger.

## GLYCOSURIA AND HYPERGLYCEMIA IN CORONARY THROMBOSIS

ADOLPH P. RAAB, M.D.

AND

MEYER A. RABINOWITZ, M.D.

BROOKLYN

The clinical association of diabetes mellitus and coronary disease has been an accepted fact for many years. Levine<sup>1</sup> in a study of 103 patients with angina pectoris, found that 68 per cent showed well defined diabetes. (In a second series of 145 similar cases he<sup>2</sup> found 23.7 per cent to have either glycosuria or known diabetes.) A study by Kahn<sup>3</sup> showed that 12 per cent of eighty-two patients complaining of angina pectoris had true diabetes and a similar investigation by Conner<sup>4</sup> revealed that 10 per cent of his patients with coronary thrombosis had diabetes.

The tendency of the arteries of diabetic patients to undergo marked sclerosis has long been known, attention having been called to the frequency in diabetes of peripheral gangrene and the presence of sclerotic vessels in limbs amputated for this reason. Warren<sup>5</sup> found thrombosis of the coronary arteries with recent or healed infarction of the heart muscle in 12 per cent of a large series of cases of diabetes that came to autopsy. Nathanson<sup>6</sup> in an analysis of seventy-four diabetic patients past the age of 50 found a 52.7 per cent incidence of coronary disease, as evidenced by severe arteriosclerosis with definite narrowing and marked obliteration of the lumen of one or more large branches. The same author in 249 consecutive autopsies on patients past the age of 50 found only 8.2 per cent showing similar changes. Hepburn and Graham,<sup>7</sup> studying by means of the electrocardiograph diabetic patients of all ages, found significant abnormalities in almost half of the cases which abnormalities for the most part were characteristic of coronary disease.

This association of diabetes and coronary closure has led many authors to look for a causal relationship between the two. Joslin<sup>8</sup> in 122 cases of angina pectoris associated with diabetes found that in 106 the onset of diabetes distinctly preceded the angina. In these cases he believed that the coronary sclerosis was secondary to the diabetes and that the duration of the latter was the important factor, since he found that diabetes of five years' duration or longer was practically always accompanied by some degree of arterial change. Joslin regarded the hypercholesterolemia of diabetes as being the responsible factor. While in those of advanced years there is the possibility that arteriosclerosis is the basis for the pancreatic changes in the young the evidence is very strong that diabetes has caused the sclerotic changes.<sup>9</sup> Root and Grubel<sup>10</sup> maintain that diabetes is always the primary disease.

that calls forth the changes in the coronary vessels and argue against the two having a common etiology. They point out that most anginal attacks appear at an age when most diabetic patients already have had their disease for from eight to ten years. Scherf<sup>11</sup> makes an interesting comment in this regard, suggesting that the upper abdominal pain of diabetic precoma may at times be on the basis of coronary closure. Edelmann<sup>12</sup> recalls that during the war there was a decrease in the incidence of diabetes and coronary closure, and that since then both have increased.

#### GLYCOSURIA DURING ACUTE PHASE OF CORONARY THROMBOSIS

The occurrence of glycosuria during the acute phase of coronary thrombosis has gradually become more widely recognized. In 1929 Levine,<sup>2</sup> discussing cases of coronary thrombosis which showed sugar in the urine during at least one stage of the disease, mentions that in one fourth of these patients the glycosuria was present only during the episode of acute closure. Two years later Cruickshank<sup>13</sup> described an interesting case of coronary thrombosis with extensive myocardial infarction in which the patient developed a hyperglycemia and glycosuria severe enough to require 40 units of insulin a day, and yet in spite of progressive cardiac failure the glycosuria and hyperglycemia entirely disappeared.

In an analysis of nine cases of coronary closure, Scherf<sup>14</sup> found one instance of long-standing diabetes, two which showed neither hyperglycemia nor glycosuria and six which revealed transitory glycosuria and hyperglycemia. Of the latter six cases, the first presented a blood sugar of 230 mg. and 0.5 per cent sugar in the urine on admission, but by the third day both the blood and the urine had returned to normal. A dextrose tolerance test performed on this patient gave normal results. His sixth case presented a very similar picture except that, although the fasting blood sugars were normal, a dextrose tolerance test revealed a high blood sugar even after two and one-half hours. No tolerance tests were performed on the other patients. Scherf was interested mainly in the diagnostic significance of this phenomenon, calling attention to the fact that the frequency of transitory glycosuria in coronary thrombosis was even greater than Levine suggested.

Gottsegen<sup>15</sup> reported a case in which previous specimens of urine were always negative for sugar and after several weeks of anginal pains a definite coronary closure developed. At the onset of the thrombosis the urine showed small amounts of sugar and the fasting blood sugar was elevated. Gradually the glycosuria disappeared only to reappear with each attack of coronary thrombosis, of which this patient had several, and again to disappear completely during the free intervals. Edelmann<sup>12</sup> corroborating the evidence of Levine and Scherf, found that of fifty-six cases of coronary closure twenty-three showed glycosuria, of which only twelve presented manifest diabetes. Eppinger<sup>16</sup> discussing acute coronary closures, speaks of the not infrequent occurrence of glycosuria and hyperglycemia at the beginning of the attack.

#### MEANING OF THIS GLYCOSURIA

What does this transient glycosuria in coronary closure represent? Levine<sup>2</sup> felt "that glycosuria is a common occurrence during the acute stage of coronary thrombosis, that it may be only transitory, and that it need not indicate any important diabetic state, that it often proves to be a concomitant of the shock and terrific pain that exists with this condition." Cruickshank,<sup>13</sup> on the basis of the severe arteriosclerotic changes found in the pancreas in his case, believed that this underlying sclerosis was the important common factor. On the other hand, Scherf,<sup>14</sup> while he felt that sclerosis of the pancreatic vessel might heighten the degree of glycemia and glycosuria, believed that the blood pressure changes were of primary importance, pointing to the initial rise in blood pressure with the appearance of glycosuria and its disappearance with the subsequent fall in blood pressure. He did not regard the increased production of epinephrine or the fever resulting from the absorption of protein products as factors. However, he did agree that drugs which were administered, such as morphine, caffeine, theobromine with sodium salicylate, and epinephrine, could call forth a hyperglycemia. He felt that another factor of contributory importance might be the acute decrease in the minute output of the heart and the thereby resulting carbon dioxide overloading of the blood and tissues making for general tissue acidosis. Since Scherf had cases in which neither pain nor shock was present he was unable to agree with Levine's interpretation of the glycosuria.

Gottsegen<sup>15</sup> regarded these patients as potentially diabetic and thought that the high mortality of coronary thrombosis prevented these subjects from developing true diabetes. This author, discussing reflex stimulation of the adrenals and Roger's<sup>17</sup> theory of embolization to the cerebral arteries regarded the duration and severity of the glycosuria and hyperglycemia as speaking against these mechanisms. He believed in a pancreatic origin, because in many cases a severe sclerotic change is found in the pancreatic arteries as part of a generalized arteriosclerosis, similar to Cruickshank's<sup>13</sup> case. He considered the transitory glycosuria the result of a reflex spasm of these already diseased vessels, the spasm resulting from the shock associated with coronary closure. He felt that when irreversible damage to the pancreas resulted there arose a chronic metabolic disturbance, i. e., diabetes mellitus.

Eppinger<sup>16</sup> felt that the absorption of the products of protein destruction is an important factor by favoring a pouring out of epinephrine. He did not regard pain as playing a part, since glycosuria is not seen in other conditions associated with pain.

Edelmann,<sup>12</sup> who often found a disturbance of carbohydrate metabolism in coronary disease, believed that the cardiac infarct resulting from an acute coronary closure led to the latent diabetes mellitus becoming manifest. He felt that diabetes not only causes sclerosis but also leads to thrombus formation, for at least one third of his diabetic patients showed absent peripheral leg pulsations, whether or not they gave evidence of intermittent claudication. While he admits other causative factors in coronary disease, he concludes that "the main thing seems to be a diabetic type of metabolism—not only in those with manifest diabetes but also apparently in those with latent diabetes." Analyz-

ing fifteen cases of coronary thrombosis, Edelmann found that seven were manifest diabetes, four gave typical diabetic blood sugar curves, and two others gave an abnormal dextrose tolerance response. Only two of the fifteen gave normal results during a sugar tolerance test. Edelmann, however, does not mention whether these observations were made during the acute phase or long after the closure. On the basis of latent diabetes Edelmann feels that the lowered blood pressure may lead to decreased circulation of blood through an already diseased pancreas, with the resulting decreased insulin production thus accounting at least in part for the hyperglycemia and glycosuria.

#### SUGAR TOLERANCE TESTS IN CORONARY THROMBOSIS

To gain insight into the meaning of this glycosuria during coronary closure, we undertook to study the carbohydrate tolerance in a group of patients who had coronary thrombosis. All gave evidence either clinically or electrocardiographically of having had a coronary closure, and in most instances both types of evidence were available. All cases in which there was a history of diabetes mellitus or which showed glycosuria at any time other than during the acute stage of coronary thrombosis were excluded. Our material consisted of twenty-one patients about evenly divided as to sex, ranging in age from 34 to 76 years, most of them being in the sixth decade of life. We have divided them into two large groups depending on whether or not they showed altered sugar tolerance, the first group permitting of several subdivisions. All tests on patients in the first group with three exceptions were performed within two weeks of their last coronary closure.

##### Abnormal Group 1 (fifteen cases)

A Four patients whose fasting blood sugar values were higher than the accepted normal and who may be considered as having true diabetes even though they failed to spill sugar in the urine. One of these cases may be questioned since the blood sugar reached normal limits by the end of the test period.

B Six patients with normal fasting blood sugars but with typical diabetic responses to the dextrose tolerance test.

C Two instances in which the blood sugar after the administration of dextrose rose to an abnormal height but by the end of the test showed values that were very low. In one of these patients (B G) hypoglycemic symptoms developed after the third hour.

D One instance in which the sugar tolerance curve stayed within normal limits during the peak of the curve but failed to reach a normal value by the end of the test.

E One case in which the value at the end of one and three-quarters hours exceeded normal but in which the blood sugar returned normal by the end of the test period and one instance in which a high value was reached at the end of three quarters hour but in which no further blood specimens were collected.

##### Normal Group 2

Six patients with normal dextrose tolerance tests. Analysis of this group reveals two patients who had their coronary closure five years prior to the date of the dextrose tolerance test, one, three and a half years prior, one two years prior, one in whom the date of his coronary closure was unknown, since he gave no positive history and showed only typical electrocardiographic changes of old coronary closure and one in whom two months had elapsed since his coronary attack. This patient at the time of his coronary thrombosis had a fasting blood sugar of 140 mg.

Since there are included in this series of twenty-one cases only two instances of hypertension, two of obesity and one of mild hyperthyroidism, these factors need not be regarded as affecting our results.

#### COMMENT

Our investigation was undertaken with the purpose of determining the frequency of disturbed carbohydrate tolerance during the acute phase of coronary closure and to prove or disprove the existence of a latent diabetes in these cases. If these individuals possess a basic decreased carbohydrate tolerance, as Edelmann believes, we feel correct in assuming that this diminished tolerance would persist long after the acute effects of the coronary closure have disappeared.

Of the twenty-one patients investigated, 71 per cent gave evidence of abnormal sugar tolerance, but when we consider only those twelve cases which were examined within two weeks of their coronary closure, we find an abnormal sugar response in every instance. And, further, when it is remembered that all known cases of diabetes were excluded from this series, it

k No history of coronary closure but positive electrocardiographic tracings.

l Five years since coronary closure.

m Twenty-two months since coronary closure.

n Two months since coronary closure, fasting blood sugar at time of coronary closure 140 mg.

o Three and a half years since coronary closure.

becomes evident that soon after the occurrence of a coronary closure the finding of an abnormal sugar tolerance curve is the rule. Of the nine cases in which a significant interval existed between the time of coronary closure and the dextrose tolerance test, only three gave an abnormal response. That 67 per cent normal curves were found in this group in which an interval was permitted to elapse while universally abnormal curves existed in the acute group, would argue against the existence of a latent diabetes as the predominant factor and speak for a temporary mechanism.

We believe that a disturbance involving the vegetative nervous centers of the brain, as has also been suggested by Hausner and Hoff<sup>1</sup> is the important factor. The transient nature of the disturbed carbohydrate

<sup>1</sup> J. Hausner and F. Hoff: *Med. Klin. Wochenschr.* 1933, 79, 1933.

tolerance and its occurrence in cases in which neither pain nor shock was prominent would be consistent with this explanation. The appearance of glycosuria in numerous types of brain disorders, such as concussion, hemorrhage and tumor, would lend support to this belief. In this connection mention should be made of Hausner and Hoff's<sup>18</sup> finding an edema of the medulla and lower pons in patients with coronary closure dying early in their attack. These investigators were able to produce the same type of brain edema in the majority of their ligations of the coronary arteries in dogs. The careful observation of cases of coronary thrombosis for medullary manifestations, and the correlation of these changes with the results of studies of the carbohydrate metabolism, may offer important evidence on this point.

A detailed discussion of the importance of the finding of a diminished sugar tolerance during coronary closure would lead too far afield and must be left for a future time. However, one cannot help but note some of the clinical implications. Insulin has been shown to be a drug that must be used with the greatest care in coronary closure.<sup>19</sup> It is therefore most important to realize the existence of an underlying altered carbohydrate metabolism in these cases and to differentiate carefully coronary thrombosis with transient hyperglycemia and glycosuria from coronary closure and true diabetic acidosis, and from diabetic acidosis with electrocardiographic changes.<sup>20</sup> As Scherf<sup>21</sup> has pointed out, the question of a true diabetes mellitus cannot always be settled with certainty at the time of the attack of coronary thrombosis. Easily understood are instances in which diabetic patients went into coma at the onset of coronary closure,<sup>21</sup> as well as the marked improvement in their diabetic status toward the end of their attack.<sup>22</sup> Our study reemphasizes the importance of doing blood sugar estimations when the urine is negative for sugar. The importance of finding the presence of true diabetes is brought out by Root and Graybiel.<sup>10</sup> They found that the prognosis of angina pectoris is worse in the diabetic patient and that those diabetic patients who died in the first year of their angina had received very inadequate treatment for their diabetes.

#### SUMMARY AND CONCLUSIONS

1 Glycosuria and hyperglycemia often occur during the acute stage of coronary thrombosis not preceded by diabetes.

2 In an effort to evaluate the influence of latent diabetes on this glycosuria and hyperglycemia sugar tolerance tests were done in a series of nondiabetic cases of coronary thrombosis. All the recent cases of coronary thrombosis gave an abnormal response to the sugar tolerance test. Sixty-seven per cent of the cases of old coronary closure gave normal sugar tolerance curves. We therefore believe that the glycosuria and hyperglycemia of the acute stage of coronary thrombosis is not dependent on a latent diabetes.

3 A disturbance in the vegetative centers of the brain is offered as an explanation for the transient nature of the glycosuria, hyperglycemia and abnormal sugar tolerance.

651 St. Marks Avenue

## SELF-PERFORMED OPERATIONS

WITH REPORT OF A UNIQUE CASE

JOHN G. FROST, M.D.

AND  
CHESTER C. GUY, M.D.

CHICAGO

Wounds self inflicted in suicidal attempts, and self mutilations by the obviously insane, the religious fanatics, the malingerers and the professional beggars of certain countries, are too well known to merit comment. When these are excluded, there remains a group of individuals known to have subjected themselves to their own surgery for therapeutic reasons, either actually or supposedly indicated. Recorded cases of this type would seem to fall into one of perhaps four major groups:

1 Surgeons who have operated on themselves

2 Normal minded individuals who have been forced by severe pain or in the absence of medical attention to perform autosurgery.

3 The sexual perverts and those suffering from an acute psychosis intense sexual excitement or anger resulting in self inflicted mutilations or amputations, usually of the genitalia.

4 Those who, because of utter ignorance or feeble mindedness, have attempted the surgical correction of some obvious disease or abnormality.

#### GROUP 1

One of the first recorded cases in which a physician operated on himself was that of the well known Paris surgeon Reclus,<sup>1</sup> who in 1890 removed a tuberculous lesion of a finger of his right hand and curetted the wound, using cocaine for a local anesthetic. Reclus reported two other cases, a physician who removed his own ingrown great toe nails, and a Turkish surgeon, Mehmed-Said who resected his own scrotum for a large varicocele.

Gille<sup>2</sup> in 1933 collected several cases of professional autosurgery from the literature. These included a herniotomy under local anesthesia by a Rumanian surgeon, Fzaicou, in 1909, a similar operation by a Frenchman, Regnauld, in 1912, and appendectomies by two Americans Alden and Kane. In "Anomalies and Curiosities of Medicine" Gould and Pyle<sup>3</sup> mention a French surgeon M. Clever (?) de Maldigny, who removed a calculus from his own bladder, aided by a mirror. Probably several more similar cases have occurred. Regardless of any difference of opinion as to what might constitute the indications for a surgeon to remove his own appendix it should be noted that in the foregoing cases no question was apparently raised as to the sanity of the patients.

#### GROUP 2

Numerous references can be found to accounts of rational individuals who, driven to desperation by pain, or in the absence of medical attention, have performed autosurgery. Cesarean section by the patient herself because of intolerable pain was reported by Cowley,<sup>4</sup> and other cases have been described. Self-performed cystotomy and lithotomy because of severe pain are

known to have occurred,<sup>6</sup> and Patterson<sup>7</sup> described a Scotchman who repeatedly applied the actual cautery to his skin for relief of severe pain from hip-joint disease. Explorers and soldiers have also reported minor amputations and other surgery of necessity that was self performed because medical care was not available. Such cases are of course rare in the twentieth century.

## GROUP 3

Sexual perversion is a psychopathic state and undue meditation over the generative function has resulted on numerous occasions in self mutilation. Gerty<sup>8</sup> has seen two patients with self-performed orchidectomies, both of whom were insane. Bradley<sup>9</sup> reported the case of a man who was sexually hyperactive and a masturbator. At the age of 40 he removed both his testicles and a few years later amputated half his penis. The older literature contains records of many similar cases.<sup>10</sup>

Atypical forms of encephalitis may give rise to localized pain with delirium such as that described by Pardee<sup>11</sup> and Bassoe<sup>12</sup> and illustrated by Conn's case<sup>13</sup> in which a girl of 21 performed self mutilation of her hand. Illustrations of self mutilation by patients with various types of encephalitis have been reported recently,<sup>14</sup> and possibly many of the earlier cases were examples of the effects of a similar but overlooked form of a cerebral pathologic condition.

Another group of self castrations and mutilations have occurred in individuals who were probably sexual perverts, but this could not be definitely proved. Jeanselme and Schulmann<sup>15</sup> report the case of a boy aged 12 years, who produced total necrosis of the glans penis, probably by wrapping threads around the organ, a known form of masturbation. Batzdorff<sup>16</sup> described the case of a man, aged 55, who suffered from urethral stricture. He amputated the penis and then removed both testicles through a second incision afterward suturing the wounds. The patient put the blame for this deed on a fit of anger, but, because of the secondary castration and the patient's feminine appearance, the author believed him to be suffering from a sexual aberration.

Of greater interest are those cases of self mutilation resulting from temporary emotional upheavals in normally rational individuals. Most of the recorded cases of this nature are the results of intemperance or of anger at being impotent. Gould and Pyle<sup>17</sup> mention several examples of the former. An excellent example of this type is a case studied by Dr. J. J. Kearns<sup>18</sup> coroner's pathologist at the Cook County Hospital, who kindly supplied the following information:

A healthy man, aged 46 accumulated some money and came to the city on a long anticipated vacation. He spent the evening

drinking in the company of a prostitute and was quite intoxicated when he retired with her. For almost an hour he was unable to obtain an erection, whereupon the woman departed. Shortly thereafter erection occurred. Intoxicated and disgusted he seized a razor and with two strokes completely amputated the penis both testicles and most of the scrotum. He died of the effects of hemorrhage several hours after his removal to a hospital. Nothing in his history or physical condition would indicate any insanity or sexual aberration.

## GROUP 4

Major autosurgery performed by the ignorant or feeble-minded individual for the cure of some obvious disorder is rarely encountered. The following case concerns one such person who twice subjected himself to major surgery with eventual recovery.

A man, aged 49, a Czechoslovakian, was admitted to the Cook County Hospital at 7 p. m., Aug. 29, 1935, suffering from a self inflicted wound in the right inguinal region through which was protruding one end of the severed small intestine.

He was operated on shortly after, local anesthesia of 1 per cent procaine hydrochloride being used. Examination disclosed

Fig. 1—Infected inguinal wound nine days after self performed bowel resection. This also shows the old self performed castration scar of the scrotum at the base of the penis and the absence of the right testicle.

an irregular ragged incision about 9 cm. long parallel with and above the inguinal canal starting about 2 cm. from the root of the penis. The fibers of the external oblique muscle were cut in their long axis, and there was an opening about 3 cm. in diameter into the peritoneal cavity. An open loop of injected and edematous small intestine protruded from the wound from right to left. The mesentery was torn for a distance of about 6 cm. upward and to the left. By following this tear the other end of the intestine was found in the abdomen. It was slightly injected but not edematous and not discharging intestinal contents. Its open end could barely be brought out of the wound, and traction on it caused pain and vomiting. These observations and the appearance of the mucosa convinced us that the part of the intestine was the upper part of the jejunum, probably not more than 6 or 8 inches (15 or 20 cm.) from its origin. The peritoneum at the site of the incision was thick, tough and somewhat scarred as if it were part of a hernial sac but no true sac could be identified. About half an ounce of intestinal contents resembling undigested vegetable greens contaminated the wound but there was none found in the abdomen. The spermatic cord was not seen. Both ends of the intestine were raised where they had been severed but showed no evidence of scarring or constriction.

The operative procedure was as follows. The wound and both ends of the intestine were cleaned and debrided some-

what The mesenteric tear was freed from adherent clots and then closed with catgut The intestine was rejoined by an end-to-end anastomosis, a double row of catgut being used with a few linen tension sutures The peritoneum was closed tight with catgut and interrupted catgut sutures were used to close the external oblique fascia Silkworm-gut apposed the skin edges, and drains were inserted into the subcutaneous space and into the inguinal canal

The postoperative course was satisfactory A liquid diet was given on the fifth day and a soft diet on the seventh A superficial wound infection developed with some fever but at no time was there abdominal distention, vomiting evidences of obstruction, or peritonitis At the end of three weeks the wound was completely healed, the patient was eating a regular full diet, and the bowels were moving regularly

Figure 1 shows the wound nine days after operation, at which time the superficial infection was most marked It also shows the scrotal scar from the previous operation and the absence of the right testicle

Although the patient had been in this country twenty-one years, he spoke English poorly and the complete history was later obtained from the patient and from other sources About two months before admission he suffered from swelling and pain of the right testicle We could not discover any cause for this Three friends had had abdominal operations and had minimized their seriousness At one time he worked as a janitor for a surgeon, and he had also seen animals castrated Being unable to pay a surgeon's fee he performed a right orchidectomy on himself, using a pocketknife which he had

Fig. 2—The 115 cm loop of jejunum self removed by the patient shown in figure 1

cleaned and sharpened He insisted that his only reason for doing so was the conviction that an operation was necessary, for which he was unable to pay He was unaware that charity service was available The scrotal operation was quite painful but there was no excessive bleeding and he made no attempt to suture the wound or seek medical care It healed slowly and was still incompletely healed at one end when first examined by us

For several months he had also suffered from a right direct (?) inguinal hernia for which he was once examined by a physician who advised him to wear a truss

The morning of August 29 the hernia was causing an aching pain Encouraged by his previous success he again operated, making the incision described and apparently opening the sac of a direct hernia He pulled out a loop of intestine and finding an area that looked rotten cut it off He returned to bed but arose later and walked about 2 miles to the office of Dr Norbert Leckband who ligated two bleeding vessels and sent him by ambulance to the Cook County Hospital where the operation described was performed about eleven hours after the injury

Dr Leckband inspected the patient's home and found much blood in the kitchen and on the bed He also found the resected loop of intestine (fig 2) which he kindly delivered to us It consisted of a segment of upper small intestine (jejunum) which after fixation in formaldehyde measured 115 cm (about 4½ inches) in length There were small hematomas in the serosal coat but both gross and microscopic examinations revealed no chronic lesion or evidence of incarceration or strangulation

September 19 the patient was transferred from the surgical service to the Psychopathic Hospital, where he was studied for one month Stanford-Binet mental tests resulted in his being given an intelligence quotient of 41.5 and a mental age of 6 years 8 months This would classify him as a high grade imbecile or a low grade mental defective His basal age was 4 years, although he passed five tests at year 5, three tests at year 6, five tests at year 7, two tests at year 8, and one test at year 9 He was cooperative attentive and polite His employer was interviewed and reported that he had worked in a green house and nursery for fifteen years, living in a small house on the property He was a good worker and dependable, took good care of his living quarters and prepared his own meals He drank occasionally but never became noisy or troublesome His employer and neighbors regarded him as a simple minded individual but not insane He had a wife and two children in Czechoslovakia and was on a list of aliens to be deported His employer was perfectly willing to have him return and the patient was discharged to be under his observation Comments and diagnoses by the attending staff of the Psychopathic Hospital on the patient were as follows

Dr Clarence Neymann "Mental defective, not committable, a grand example of what a primitive mind will do under certain circumstances" Dr Morris Braude "Probably feeble-minded by our standards but not by his own—not committable" Dr Ralph Hamill "Mental defective, as good as any" Dr Francis J Gerty "Feeble-minded, not committable"

#### COMMENT

This case would seem to be unique in medical annals, as none other quite like it has been recorded to our knowledge One somewhat similar, but probably belonging in group 3, was described by Osinga,<sup>19</sup> who examined the body of a Javanese boy, aged 13 years, who had cut open a scrotal hernia and resected two portions of small intestine The boy was apparently normal mentally until a scrotal hernia developed, which caused mental disturbances because of his fear that he would not "attain manhood" It was during a period of depression that he operated on himself with a penknife His cries brought relatives, who carried him to a distant hospital, but he died on the way of hemorrhage, about four hours after the mutilation

The case here reported would seem to be an outstanding example of group 4 previously mentioned The patient had no demonstrable psychosis or sexual perversion His self-performed operations were undertaken for what seemed, to his simple mind, to be good reasons The case is also remarkable in that the patient completely recovered after two separate self-performed major operations, castration and bowel resection, the former without any medical attention and the latter with surgical anastomosis eleven hours after the injury

**Loss of Appetite and Vitamin B**—In cases of severe deprivation of vitamin B the loss of appetite becomes a serious matter In fact the condition of vitamin B deficiency is very largely one of starvation from loss of interest in food Often the lost appetite has been restored with dramatic promptness upon giving vitamin B either in the form of a natural food or of a concentrate It is a true effect upon appetite as a function of the body and not merely a matter of making the food appetizing for when the vitamin is given separately the experimental animal will return with appetite to the same food which it had previously refused To what extent it is feasible and desirable to stimulate the appetites of patients by administration of artificial concentrates of vitamin B is a problem for the physician—Sherman H C Food and Health New York Macmillan Company 1934

PERMANENT PIGMENTATION FOLLOW-  
ING APPLICATION OF IRON SALTS

FOR THE TREATMENT OF IVY POISONING

EUGENE F. TRAUB, M.D.

NEW YORK

AND

JOSEPH S. TENNEN, M.D.

STAMFORD, CONN.

In 1873 White<sup>1</sup> first called attention to the use of iron salts in the treatment of ivy poisoning. In 1886 Browning<sup>2</sup> described the use of ferric chloride in the treatment of rhus poisoning, but its popularity was greatly advanced by the work of McNair<sup>3</sup> in 1921

Fig. 1—Front view of patient showing one of the largest solid areas of pigmentation.

Many others<sup>4</sup> have attested the usefulness, harmlessness and efficacy of preparations of iron salts in both the treatment and the prophylaxis of rhus poisoning, some authors have gone so far as to suggest the remedy as the first choice in the chemotherapy of rhus dermatitis.

The prevalence of rhus poisoning and the apparent rarity of complications in cases treated by iron salts prompts the report of these with their unusual sequelae.

## REPORT OF CASES

CASE 1—Miss M. F.,<sup>5</sup> an American aged 46, a writer presented herself for consultation to one of us (J. S. T.) Sept. 10, 1935, with evidence of an asymmetrical bilateral and irregular group of pigmented lesions, located on the face, neck, upper part of the chest, and forearms. The lesions were fairly circumscribed, uniform smooth and slightly depressed varying from 1 to 2 mm. in diameter, and one large lesion on the left side of the upper lip measured 3 by 4 cm. The lesions varied

from a light brown to a deep copper color. They showed no evidence of infiltration and were noninflammatory. No subjective symptoms were present.

Aug. 14, 1935, the patient was exposed to various leaves and grasses in a wooded section of the country. When she sat down to rest she noticed 'hive-like lesions' on the left forearm preceded by needle-like pains. The next morning she noticed a 'cluster of red spots' on the left side of the neck and over the left side of the upper lip. A calamine ointment was then applied until the next day, when her face and neck began to swell. August 16, wet dressings of a ferrous sulfate solution were prescribed and applied to the lesions for twenty-four hours, without relief of symptoms. This was discontinued and wet dressings of a 5 per cent solution of ferric chloride in a half and half mixture of alcohol and water were ordered, and she was also advised to puncture the vesicles that had formed in the interim. After applying the ferric chloride solution to the lesions which now were denuded of epidermis the patient states that her skin took on the appearance of a colored person's with a diffuse discoloration and pigmentation of the affected parts. The use of this solution was then discontinued and a calamine lotion used until the acute stage had completely subsided, leaving the pigmentation described.

With a punch biopsy instrument a small piece of tissue was removed from a pigmented area on the left forearm. The histopathologic report on this tissue was as follows:

There was a slight edematous vacuolization of many of the prickle cells and a moderate edema and dilatation of the blood vessels of the upper corium. The inflammatory response was slight. A large number of chromatophores was to be found about the blood vessels and between the collagen fibers of the upper corium. Perl's stain showed blue granules in the chromatophores. The diagnosis was dermatitis with deep seated pigmentation.<sup>6</sup>

The remaining laboratory studies were essentially negative. A blood count revealed platelets, 310,000; hemoglobin, 85 per cent; grains of hemoglobin, 12 grains per hundred cubic centimeters; total red blood cells, 4,000,000; total white blood cells, 7,000; differential count: lymphocytes, 45 per cent; polymorphonuclear leukocytes, mature, 52 per cent; monocytes, 1 per cent; eosinophils, 2 per cent; and basophils, 0 per cent. The red blood cells appeared normal.

The temperature was 98 F., the bleeding time one and one-half minutes; coagulation time four minutes; the tourniquet

Fig. 2—Lateral view showing punctate spots of pigmentation marking sites of previous vesicular eruption.

test negative, the blood culture, negative after two weeks and the sedimentation time fifteen minutes in one hour (slightly above the normal rate). The fragility test showed that hemolysis began at 0.4 per cent and was complete at 0.375 per cent (normal).

CASE 2—Mrs. L. S., aged 38, a housewife born in the United States was seen privately in September 1925 by one of us (E. F. T.) because of a pigmentation of the skin of the face.

<sup>6</sup> From the Pathological Laboratory of the Skin and Cancer Unit of the New York Post Graduate Medical School and Hospital (E. F. A. Bartel, M.D., and Elmer Whitney, A.B., M.S.).

neck and arms following treatment for a dermatitis venenata (ivy) with iron salts. The patient stated that her family physician had treated her early in August of that year for a typical attack of ivy poisoning, using a 5 per cent solution of ferric chloride in 50 per cent alcohol. The areas of pigmentation, which occurred rather extensively on the locations mentioned, failed to disappear when the skin was peeled, for which strong doses of ultraviolet rays were used. More radical measures were not undertaken because of the danger of permanent scar formation. The pigmentation was permanent.

Fig 3—Lateral view showing punctate spots of pigmentation marking sites of previous vesicular eruption

Through the courtesy of Dr George Miller MacKee<sup>7</sup> we are privileged to report briefly four additional cases of pigmentation that came under his observation about fifteen years ago, shortly after the published account of good results in ivy poisoning with the use of the iron salts. He was careful to note that in each instance there had been a severe dermatitis venenata caused by *Rhus toxicodendron*. In each case the eruption was acutely vesicular and exudative in areas. It was his impression that the resultant pigmentation, which was apparently permanent, occurred only in the areas that were eroded at the time the iron preparation was applied as a wet compress.

#### COMMENT

McNair<sup>8</sup> believes that part of the remedial value of iron chloride in *rhus* dermatitis may be due to its ability to form a layer of precipitated and denatured protein on the injured surface, which acts as a protection against the penetration of the poison. He also states that the coagulation effect on protein and the irritant properties of iron chloride cause the lesions to become slightly depressed and darkly colored but result in no scarring of itself. The possibility of the ferric chloride penetrating the tissues and becoming fixed by them has apparently never before been reported. The course of events in these cases apparently is similar to the production of tattoo marks. Although there was some slight difference in the intensity and color of the pigmentation in the different cases, a rather deep golden brown pigmentation seemed to be the striking and characteristic feature in all of them. The pigmentation was exceedingly conspicuous and disfiguring, and as the lesions were to be found chiefly on the exposed parts of the body, that is, the face, neck and arms, the cosmetic defect was a serious one. The deep location of the pigment between the collagen fibers of the upper corium (case 1), indicates that little spontaneous improvement is to be expected and practically assures

the permanence of the lesions. Furthermore, the widespread distribution of the lesions, especially those involving the face and neck, precludes any attempt at removal without the great risk of leaving undue and unpleasant scarring. The fact that it is possible for such accidents to happen at all makes one hesitate to advocate the indiscriminate and widespread use of this type of treatment for a disorder that is usually easily controlled by other remedies entirely devoid of the danger of sequelae. The use of iron salts to be applied as a lotion, compress or wet dressing in any vesicular, bullous or exudative dermatoses should be discouraged, because the accident could occur equally well in the treatment of eruptions other than from poison ivy.

#### CONCLUSION

- 1 Unusual sequelae have occurred in cases of *rhus* dermatitis treated with iron salts.
- 2 There have been cases of widespread permanent pigmentation as a result of the treatment.
- 3 The medical profession is made aware of the fact that ferric chloride is not as harmless as it has been led to expect.

Fig 4—Section of skin removed from one of the pigmented areas showing the deposit of pigment both deep in the epidermis and in the upper corium

- 4 Examples of the kind herewith reported are probably comparatively rare.
- 5 It has been demonstrated that the pigment was deposited around the blood vessels and between the collagen fibers of the upper corium.
- 6 The use of iron salts applied as a lotion, compress or wet dressing should be discouraged in all vesicular, bullous and exudative dermatoses.

A TWENTY-FIVE-YEAR-OLD ERROR  
IN MEASURING A GIANT

CHARLES D HUMBERD, MD

BARNARD, MO

The case of modern giantism which is most frequently cited is that of John Turner, aged 36, the former driver of a brick-wagon, who is item 32 (surgical No 25947) in Dr Harvey Cushing's monograph.<sup>1</sup> Numerous essayists have pointed to this record as that of an outstanding specimen among the "tall boys," so he has become a rather permanent fixture in the literature on giants. Original references to Turner's case can be found nowhere else in print, however, although his personal history here states that "of late he has been an inmate in various hospitals." Dr Cushing records that this giant's height, measured after death, was 8 feet 3 inches (251.5 cm). I am convinced that this measurement was in error by at least 1 foot, perhaps more, for the reasons which follow.

Cushing's text presents two good full length photographs of the nude and barefooted giant, as figure 220 on page 163 and figure 224 on page 166. An inspection alone shows that this patient's elongation was quite apparently that of the infantilism-eunuchoid, non-acromegalic type. To one who has studied circus giants and applied a tapeline to them it is evident from these photographs that Turner, though he was huge, was far short of 8 feet in height. In the write up of the physical examination the doctor states that "his height is estimated at about 8 feet." It is known that the eye always overestimates the exact height of giants—exhibition giants take advantage of the public's credulity, for it is axiomatic that no giant (or no dwarf) ever told the truth about his dimensions! The majority of them, too, customarily do a bit of tinsel falsifying in the number and the size of their immediate relatives.

Several assorted measurements of Turner are available in the text on page 166.

A Each of his clavicles was 21 cm in length.

B The arm measured 110 cm from the acromion to the fingertip. But because the fingers in both photographs are flexed this dimension cannot be used. However the length from the base of the median metacarpal to the tip of the middle finger was 27 cm. By difference, this leaves an acromion metacarpal length of 83 cm.

C The humerus measured 47 cm from its tuberosity to the external condyle.

D The radius was 37.5 cm in length. (Note C + D or 47 + 37.5, = 84.5 cm, compare measurement B, which is given as 83 cm.)

E The length of the flexed middle finger from knuckle to tip was 17 cm. (Note that the roentgenogram figure 225 is stated to be natural size but on it this finger measures at most only a scant 15 cm; this measurement has been checked against three different copies of the plate to discount any error from paper shrinkage. On this plate the length of the index finger is 12 to that of the middle finger as 132 mm 144 mm or as 11 12. So the index finger, which can be nicely measured as extended in figure 220 was 15.5 cm long.)

F The femur measured 62 cm from the great trochanter to the knee joint.

Other measurements of Turner can be extracted from the account as follows:

Occipitofrontal circumference of the head 61 cm

Width of shoulders between tips of the acromion 36 cm

Scapular spines 20 cm and vertical length of the scapulae 25 cm

Circumference of the middle finger at the first joint, 10 cm

The nail on this finger was 2.3 cm long

Circumference of the pelvis, 109.5 cm

Circumference of the left knee, 58.5 cm

Circumference of the ankle, 48.5 cm

Circumference of the great toe, 13.5 cm

Measurements of the sella turcica 22 by 27 cm.

Total weight of body, 275 pounds (124.8 Kg)

Individual organs had the following weights: brain 1,884 Gm, heart, 520 Gm, pancreas, 70 Gm, spleen, 1,000 Gm, kidneys, 700 Gm, and testes 15 Gm.

When figure 220 is studied carefully it will be noted that the giant is stooped though his head is erect. If

Fig. 1—Reproduction of photograph especially posed in counterfeiting of Cushing's figure 220. The newspaper editor on the right has the same height as Dr. Crowe (5 feet 8 inches (173 cm)). The giant is 21 years old, weighs 180 pounds (81.6 Kg) and is 6 feet 7 inches (201 cm) tall; his face somewhat resembles Turner's and might suggest an infantilism type of gigantism but he has none of the stigmata of this disorder. It will be noted however that he appears to be almost as tall as 8 feet 3 inches (Turner).

a pair of dividers is used to take off the dimensions in this photograph and the points of the instrument are then measured against a scale, the results will be as follows:

The giant's height in this illustration is 152 mm

A Each clavicle here measures 16 mm

B The acromion metacarpal length is 65 mm.

C The humeri are each 32 mm long

D The radii are each 29 mm

E The left index finger is 12 mm

F The femur is 48 mm

<sup>1</sup> Cushing, Harvey: The Pituitary Body and Its Disorders. Philadelphia: B. Lippincott Company, 1912, pp. 16, 10.

Solving each of these proportions gives

A 16 mm	21 cm	152 mm	199 cm
B 65 mm	83 cm	152 mm	194 cm
C 32 mm	47 cm	152 mm	195 cm
D 29 mm	37.5 cm	152 mm	196 cm
E 12 mm	15.5 cm	152 mm	196 cm
F 48 mm	62 cm	152 mm	196 cm

The same photograph also shows Dr S J Crowe, whose height it is stated was 5 feet 8 inches (173 cm). The doctor is not standing erect here, and a careful experimental posing of a man of this height and due attention to the perspective or foreshortening leads me to deduct 8 cm from his stature because of his posture

Fig. 2.—The same pair 6 feet 7 inches (201 cm) and 5 feet 8 inches (173 cm)

In the photograph it is 130 mm from the top of Dr Crowe's head to the floor which gives

130 mm	165 cm	152 mm	193 cm
--------	--------	--------	--------

The same chair appears in both figures 220 and 224, and the legend for the latter calls it a "usual 18-inch chair" Eighteen inches=46 cm In figure 220 the seat of the chair is 36 mm from the floor So

36 mm	46 cm	152 mm	194 cm
-------	-------	--------	--------

All these final figures coincide very closely, so it must be concluded that their weighted mean, 195 cm, or 77 inches (6 feet 5 inches), represents Turner's height quite exactly in the stooped position of this photograph

If a man of 8 feet 3 inches (99 inches) bows himself over until his height is lowered to 6 feet 5 inches (77 inches) he would appear very much more stooped than this photograph shows, for this seven ninths of his height would be the equivalent of a man of 5 feet 8 inches (68 inches) stooping over until his head is less than 53 inches (4 feet 5 inches) from the floor, i e, 99 77 68 53 A quick test of such a stoop will show at once that Turner has not bent himself to any such extent, for it puts one's spine quite nearly horizontal

Turning now to figure 224, one finds Turner seated in a chair, and his posture is fairly erect Again with dividers and a scale one can take off these dimensions from the photograph

From the crown of the head to the left trochanter,	47 mm
From the left trochanter to the left knee,	32 mm
From either knee to the floor at the heel,	31 mm
Photograph's total height, if Turner were standing,	110 mm

And now the measurements of this photograph

B The arm, from acromion to metacarpals,	43 mm
C The left humerus,	24 mm
D The left radius,	19 mm
F The left femur,	32 mm
X The height of the chair's seat,	23 mm

If these proportions are analyzed by the measurements just quoted, the result is

B 43 mm	83 cm	110 mm	212 cm
C 24 mm	47 cm	110 mm	215 cm
D 19 mm	37.5 cm	110 mm	217 cm
F 32 mm	62 cm	110 mm	213 cm
X 23 mm	46 cm	110 mm	220 cm

From these it can be concluded that Turner's height when "straightened out" almost erect was their average, 216 cm or 85 inches, which is, incidentally, a very impressive height

A comparison can also be made with figure 246, on page 183 Here a woman 67 inches (170 cm) tall holds the same two chairs, and the tops of their backs are just at the level of her trochanters This height strikes Turner below his trochanters, just the length of one of his clavicles, or, in figure 220, 16 mm below the trochanter Here the height of the right trochanter is to his whole height as 84 152, assuming that his knees are bent just about as much as his shoulders are stooped So we have

84	—	16	84	170 cm	210 cm
----	---	----	----	--------	--------

210 cm = 82 3/4 inches, or 6 feet 10 1/4 inches, if Turner had the bodily proportions of the woman But he was a bit longer legged, proportionally

Really an 8-foot giant, or even one of 7 feet 6 inches, no matter how misshapen, would in the poses of either figure 220 or 224 appear far more bulky and vast Circus giants can't use these ordinary opera chairs so comfortably

As to the sources of the error, what occurred, in all likelihood, is that on the autopsy table Turner's full stretched height, thoroughly straightened at knees and hips and with the head thrown far back, was hastily measured by either Dr Crowe or Dr Sharpe with an ordinary foot rule ("under most inauspicious circumstances," says the text), and it was recorded as 8 feet 3 inches, instead of an actual 7 feet 3 inches The figure 251.5 cm was of course obtained by multiplying 8 feet 3 inches (99 inches) by 2.54, which is the usual conversion factor for inches to centimeters The read-

ing undoubtedly should have been 7 feet 3 inches, or 87 inches, which is equivalent to 221 cm

Turning back to figure 220, Turner, it is easy to see, has stooped over so that his height of 7 feet 3 inches (87 inches) is reduced to the calculated 6 feet 5 inches (77 inches), and the photograph clearly shows him bent over by this amount

Cushing is not the first to err in 'measuring' a giant. The "8 feet 10 inch" giant who was examined after his death from diphtheria at the Willard Parker Memorial Hospital, New York by Dr Douglas Symmers,<sup>2</sup> was one of the two Hugos, and he was but 230 cm (7 feet 6½ inches) tall when Launois measured him a few months before Topinard's celebrated Finlander, "283 cm or 9 feet 4 inches tall," is proved by Langer<sup>3</sup> to have been the Finnish giant Daniel Cajanus who died in 1749. The bones of Cajanus are in the Leyden Museum, and his real height was 222 cm, his femur measures 61.5 cm, or just 0.5 cm less than Turner's, whose twin he actually was in height. Symmers probably accepted a press agent's statement, Topinard's error arose from a mistaken idea of the equivalents of certain national standards of length.

Thomas Hasler (not "Hessler," as Cushing calls him), described by Buhl,<sup>4</sup> was 227 cm tall, his skeleton was mounted and is still to be seen in the museum of pathology. His right femur measures 67 cm (Turner's was 62 cm), the left was somewhat shortened by an old fracture of its neck.

The 19 year old giant at Bushire, Persia, described as 10 feet 6 inches (3.2 meters) tall by Prof D. H. Fuchs<sup>5</sup> actually measured 220 cm (7 feet 2½ inches) when he became patient 1084 at the Imperial Hospital of the Imperial Health Department at Teheran, Persia, according to a complete copy of his hospital record lately sent me by Hon. Charles C. Hart of the U. S. legation at Teheran.

The skeleton of the unknown Kentucky giant, in the Mutter Museum at Philadelphia, has a total height of 230 cm. The clavicles are 21.2 cm long. The humerus, 47.5 cm, and the radius 36 cm are practically the same as Turner's, the femurs, 65.5 and 66.6 cm respectively, right and left, exceed Turner's. Turner's femurs are also shorter than those of Cornelius Magrath, 217 cm tall, whose skeleton is in Dublin, and of Charles Byrne, the Irish giant, 231 cm tall, whose osseous framework was surreptitiously salvaged by John Hunter for the Museum of the Royal College of Surgeons at London. The tallest giant now on exhibition in America is the acromiégalic "Jack Earl" (Jacob Ehrlich of El Paso, Texas), who measures 7 feet 7½ inches (233 cm) tall, his trochanter-knee length is 68 cm.

Comparisons alone would compel one to say that if Dr Cushing's figure of 8 feet 3 inches for the giant's height were correct poor Turner must have been very strenuously and ruthlessly unjointed when he was measured after his death in January 1911! So I repeat my conviction that he was only 7 feet 3 inches tall.

I have never been able to find an absolutely reliable account of a human being who has ever attained as much as 8 feet (244 cm) in height.

## THE WATERHOUSE-FRIDERICHSEN SYNDROME

### A REVIEW OF THE LITERATURE AND A REPORT OF TWO CASES

E. E. AEGERTER, M.D.

NEW YORK

The disease now known as the Waterhouse-Friderichsen syndrome was recognized as an entity by Little<sup>1</sup> in 1901. He published a report of four cases of his own and in reviewing the literature found eight other cases which he stated had been "hitherto unclassified." In his series he may have included at least one that was a purpura of a different etiology. In 1911 Waterhouse<sup>2</sup> in England reported a case and reviewed fifteen others. He described the syndrome and gave an accurate account of the symptomatology and pathology. Friderichsen<sup>3</sup> in 1918, in Germany, published a report of two cases of his own and gave a comprehensive review of the twelve cases reported by Little and sixteen other cases collected from the literature at large. In 1934 Bamatter<sup>4</sup> published a report of thirty-eight cases, two of which were his own. In a rather thorough search of the literature I have found reports of fifty-five cases that seem undoubtedly to belong in this category and shall report a recent case of my own and one case from the records of the Willard Parker Hospital which in history, symptomatology and pathology give the typical characteristics of the disease.

**CASE 1**—A white boy aged 7 years well developed and well nourished, according to the mother, had been unusually healthy and strong. He had had a hemangioma of the left auricle at birth which had been given several radium treatments by competent therapists. He had had measles at 2 years, pertussis at

4 years and mumps at 5 years. He had been in apparent good health up until 5 p m on the day of onset of this illness. At that time he complained of pain in his knee. There was no history or evidence of trauma. Shortly afterward he complained of malaise and refused to eat his supper. At 10 30 he vomited, complained of weakness and asked to be lifted back into his bed. He slept throughout the night, but at 6 30 a m his mother was attracted by the child's color. He appeared bluish all over his body. She found that he had been incontinent of urine and feces during the night. The child was stuporous and irrational. His breathing was heavy. A physician was summoned and at 10 o'clock he found the child semicomatose and cyanotic, with a beginning purpuric rash and a weak and rapid pulse.

He was admitted to the hospital at 10 50. The respiratory rate was 36, and his breathing was labored. The pulse at the wrist was imperceptible, the apical pulse was rapid but regular. The skin showed a startling cyanosis. Over the entire body excepting the palms, soles and scalp there was a macular purpuric rash the areas varying from a few millimeters in diameter to palm size. They were frequently confluent. These areas were almost solid over the back and the surfaces of the extremities that touched the bed. Scattered over the body were

Section of adrenal under low power showing destruction of medulla and fascicular layer of cortex by hemorrhage

numerous petechiae. The conjunctivae and mucous membrane of the fauces and pharynx were deeply injected. The neck was stiff and Kernig's sign was present in both legs. The temperature on admission was 106 F. The lungs were clinically normal. There was a marked somatic hyperesthesia. A spinal tap was done. The fluid was crystal clear under normal pressure, contained 5 mononuclear cells per cubic millimeter, had a normal albumin, globulin and sugar content and grew no organism on culture. In attempting a blood examination, great difficulty was experienced in obtaining a sufficient amount of blood from a needle puncture wound. Enough for a smear was extracted by the technician. The differential count showed 42 per cent polymorphonuclear leukocytes and 58 per cent lymphocytes. About 75 per cent of the former showed vacuoles in the cytoplasm, approaching the size of the nuclear lobes. The temperature rose to 107 F, respirations became more labored the cyanosis deepened the heart sounds became more faint and the patient died at 11 40 fifty minutes after admission and nineteen hours after the initial symptom. Antemortem and postmortem blood cultures produced a profuse growth of *Micrococcus meningitidis*. Cultures made from the brain post mortem grew the same organism.

At autopsy petechiae were seen in the mucosa of the mouth, larynx, stomach and intestine. Small hemorrhages from 1 to 3 mm in diameter were found in profusion throughout the

peritoneum, pleurae and pericardium. The lungs, kidneys, spleen and liver showed marked congestion with beginning toxic changes in the two latter. The thymus was large, weighing 38 Gm, and hyperplastic. The vessels of the surface of the brain were engorged, the brain was wet and heavy but there was no overt meningitis. The pituitary was deeply congested. The adrenals presented the picture of major interest. They were extremely large, 8.5 by 3 by 2.5 cm, appearing almost as large as the kidneys, weighing 15 and 18 Gm each. They were a deep purple and the capsules were tense with blood.

CASE 2—A white boy, aged 5 years, well nourished and well developed, was admitted to the hospital at 2 30 p m, in November 1928. The past history revealed that other than pneumonia at 3 years, the child had been perfectly healthy until the onset of this illness on the afternoon of the preceding day. The child complained of headache. He was found to have a fever. He vomited.

On admission the patient was cyanotic. The respirations were shallow. The pulse was imperceptible at the wrist and the apical pulse was 168 per minute, the heart sounds were distant. The temperature was 107.6 F. There were scattered rales over both lungs and a petechial rash was present over the entire body. The pupils were dilated and did not react to light. The head was retracted and the back rigid, and the extremities were spastic. A spinal tap was done. The fluid showed an increase in tension, a "large increase" in cells, with 98 per cent polymorphonuclear leukocytes, a few gram-negative diplococci mostly extracellular, a four plus albumin and globulin reaction and a reduction in sugar content. Meningococcus was grown from the spinal fluid. Many of the petechiae in the skin developed into ecchymoses. The child died two and one half hours after admission, about twenty-four hours after the onset.

At autopsy, petechiae were found in the pleurae, pericardium and serosa of the peritoneum and mesentery. The surface vessels of the brain were injected. The lungs were congested. There was a beginning purulent pericarditis and meningitis. The mucosa of both the small and the large intestine showed petechial hemorrhages. The thymus was large, weighing 19 Gm. The liver and spleen showed moderate toxic changes. No hemorrhage was noted grossly in the adrenals but under the microscope they showed advanced congestion and definite hemorrhage especially in the fascicular layer. They weighed 10 Gm each.

#### SYMPTOMATOLOGY

The history and symptoms of case 1 are so frequently repeated in the reports of other cases that one is compelled to feel the importance of recognizing the Waterhouse-Friderichsen syndrome as a disease entity. By far the majority of the cases occur in patients under the age of 1 year, though it is seen not infrequently in adults. Herrick<sup>6</sup> has seen many cases in army practice. Of the fifty-seven cases under discussion, fifteen of the patients, or 26 per cent were under 6 months of age. Twenty-nine, or 52 per cent, were 1 year or younger, and forty, or 70 per cent, 2 years or younger. Of the fifty-seven patients there were six adults, three of whom were over 50. Of the forty-seven cases in which sex was mentioned, twenty-six of the patients were males and twenty-one females.

The typical history states that the patient was in perfect health until the onset of the disease. Of those reviewed, the only cases without sudden onset were complicated with other conditions, which might easily have altered the characteristic early signs.

The initial symptom may be restlessness, headache or malaise but is more likely to be referred to the gastro-intestinal tract. Abdominal pain is mentioned frequently enough to make its occurrence more than coincidence. Thirty-one of the histories revealed vomiting as an early symptom. This was found to be as frequent in adults as in children and infants. Loss of

6 Herrick, W. W. Case of Purpura Fulminans. J. A. M. A. 76: 22 (Jan. 1) 1921 (ca. es. 21-22).

appetite, a flushed face, and perhaps a moderate fever may be the only signals to warn the parent of the child's impending condition. The patient soon becomes stuporous. This may be mistaken for healthy slumber. It is not infrequent to find the patient when he retires complaining of feeling below par and, the following morning, discover him comatose and moribund.

Cyanosis is usually noted about ten or twelve hours after the onset. It is so startling that it attracts immediate attention. This is frequently the first symptom that impresses the gravity of the condition on the mind of the relative or friend and brings the patient to the physician. Twenty-seven of the reports mention cyanosis as an outstanding feature of the symptomatology. The lips and nails of the patient are blue and the skin is livid. Two reports mention alternation of cyanosis with pallor. In one patient a peculiar mottled appearance was evident, especially over the face and hands.

Soon after the cyanosis has manifested itself, petechiae may be noted scattered over the trunk, face and extremities. Their onset is sudden and they increase in size with astonishing rapidity into a vivid, purple macular rash. The mother of our patient watched these "spots" develop while giving the patient a bath. In a small proportion of the cases the hemorrhage into the skin does not advance beyond the petechial stage. Out of the fifty-seven cases studied, thirteen showed neither petechiae nor macular hemorrhage. As the areas increase in size they become confluent and the skin takes on a blotchy appearance, some of the areas being the size of the palm or larger. Over the contact areas, i. e., the buttocks, back and extensor surfaces of the arms, the entire surface is involved so that it assumes the appearance of postmortem lividity. The rash remains until death, usually from six to ten hours later.

At this time the patient is found to be stuporous or semicomatose. One may usually find moist rales scattered over the chest, and the respiratory rate may be increased. In thirteen cases dyspnea was recorded and in a considerably fewer number stertorous breathing and Cheyne-Stokes respirations were noted. The patient may be incontinent. One or more convulsions were listed in twelve of the reported cases. Symptoms of early meningeal involvement are not uncommon at this time. This may be manifested by headache, altered reflexes and a feeling of profound weakness. It is of interest to note that, of the patients who received spinal taps, in only six were there abnormal manifestations. In three there was an increase in cells, in six the meningococcus was isolated from the spinal fluid and in four there was an increase in tension. There is a characteristically septic spiking temperature, which may range from subnormal to 108 F. Early in the disease the increase in pulse rate is proportionate to the rise in temperature, but as it progresses the rate mounts as the circulatory system fails. The rhythm was affected in only one case, but the quality is generally found to be poor and fluctuating. The radial pulse usually becomes imperceptible at about the period of the development of the rash, and at this time also the heart sounds are heard to be indistinct and of poor quality. In three cases injections of epinephrine seem to have caused very temporary improvement in the cardiovascular picture. The blood pressure may be found to be low.

A leukocytosis would be expected. This is mentioned in only seven of the reports. A shift to the left in the

cells of the myelogenous series was noted by Bamatter. Two reports mention difficulty experienced in expressing enough blood for counts and smears by the usual needle-prick method. This was true in our case. The technician finally contented herself with only enough blood to make smears. No Gram stain was done on these smears. Most of the cells were vacuolated and showed other signs of degenerative change. Unfortunately the smears were discarded before a thorough search for organisms was made.

Other signs and symptoms mentioned in five or less reports are a low surface temperature with high mouth and rectal temperatures, muscle flaccidity, low blood sugar, chills, tremor, cough, edema of the lower extremities, strabismus, elevation of the nonprotein nitrogen of the blood, and rigidity of the abdominal muscles.

The importance of finding the organism in the blood stream is stressed by McLean and Caffey.<sup>7</sup> In a series of cases of meningococcal meningitis presenting purpuric exanthemas, they were able to demonstrate intracellular gram-negative organisms in 83 per cent. They made a puncture wound through one of the hemorrhagic skin lesions and from the blood expressed they made smears which they stained by Gram's method. In a series of sixteen of their cases, in which smears and blood cultures were taken simultaneously, the former were positive in thirteen and the latter in ten. This method was used by Netter, Salamer and Wolfson<sup>8</sup> in 1916. They believe that the hemorrhage is due to the presence of meningococci around the vessels.

#### PATHOLOGY

The most constant pathologic condition at autopsy is massive adrenal hemorrhage. In the fifty-seven cases studied, all but two came to postmortem examination, and of the fifty-five cases fifty-two showed bilateral adrenal hemorrhage, three showed unilateral adrenal hemorrhage (all on the right side), and in only one was hemorrhage not mentioned. In one case the capsule had been ruptured, resulting in a hemorrhagic peritonitis. In our case the glands were immense and of a necrotic purple. The capsules were tense and, when opened, grossly resembled blood cysts. No normal glandular tissue could be made out on either side. Under the microscope it was seen that in most places the medullary tissue had completely fallen away and in others was replaced by extravasated blood. Around the capsule there remained a fringe of recognizable cortical tissue. As these cells approached the fascicular layer, they became more widely separated and compressed by blood dissecting in from the medulla. In most places there was complete obliteration of all three glandular layers.

Twenty-three reports mentioned small hemorrhages into the serosa of the peritoneum, pleurae or pericardium, or all three. Fifteen mentioned injection of the superficial vessels of the brain, and six noted pulmonary congestion. Fifteen reports recorded enlargement of lymph nodes or Peyer's patches, or both, and nine mentioned a large thymus. The latter was true in case 1 in which the thymus of a 7 year old child

A New Case of Hyperacute Purpura with Cerebro-meningitis. Recognition of Its Meningococcal Nature During Life by Microchemical Examination. *Brit J Child Dis* 11: 104 (April-June) 1917 (case 23).

weighed 38 Gm Rabinowitz<sup>9</sup> notes that status thymolymphaticus has often been associated with an insufficiency of the chromaffin system. A few reports mention hemorrhage into the mucosa of the gastrointestinal tract. This, according to McLean and Caffey, may account for the abdominal pain and diarrhea sometimes seen.

It is interesting to correlate the pathologic changes found with the more or less characteristic clinical and laboratory manifestations in this disease. Such symptoms as hypotension, a feeling of weakness, low blood sugar, muscle flaccidity, rise in the nonprotein nitrogen of the blood, vomiting and circulatory collapse have long been accredited to the functional failure of the adrenal glands. Rogoff<sup>10</sup> states that the experimental animal may suffer a loss of both adrenal medullas and one cortex without radically influencing his life and health, and that there is "no good evidence that epinephrine plays a role in the maintenance of normal blood pressure." The functional correlation between the adrenal medulla and cortex is uncertain. It is known that in the lower forms they exist as two separate bodies and that removal of both cortices in experimental animals invariably causes death. Loeb<sup>11</sup> clearly shows that the adrenal gland exerts a controlling influence on the metabolism of sodium ion excretion, depleting the blood of both sodium and chloride. Concurrent with this loss in sodium is a relative dehydration through the kidneys. Thus the actual blood volume may be diminished, which conceivably might result in shock with its resulting chain of symptoms. There is no proof that death in the Waterhouse-Friderichsen syndrome is due to adrenal failure rather than to toxicity caused by the invasion of the blood stream. It is of first importance, therefore, to note what happens to the sodium metabolism in this disease. If there is a marked fall in the blood sodium concentration, one may assume that death is probably due, in part at least, to the collapse following adrenal destruction.

The chain of signs and symptoms that characterize the Waterhouse-Friderichsen syndrome is doubtlessly caused by a bacterial invasion of the blood stream. Up until 1916, the number and variety of organisms cultured from the blood, adrenal gland and skin lesions, including the streptococcus, the staphylococcus, colon bacillus *Bacillus pyocyaneus* and *Bacillus Friedlander*, suggests either that this relatively constant chain of symptoms is caused by numerous different and unrelated organisms or that the methods of culture were faulty. Since almost universally the literature after 1916 subscribes the cause to *Micrococcus meningitidis*, one is more inclined to believe the latter. The splendid work of MacLagan and Cooke,<sup>12</sup> McLean and Caffey, Bamatter and several others leaves little doubt that the disease is most frequently caused by the meningococcus. That some of the symptoms may be caused by other organisms is no less certain. After reviewing the literature, one cannot help but feel that the meningococcus is the sole cause of the syndrome, but only accurate bacteriologic methods, employed in a larger series of cases, will settle the question definitely. Should it be

found that the meningococcus is the only organism causing the disease, the name of the syndrome should be changed to fulminating meningococcemia.

When one realizes the preference of the meningococcus for localization on the brain and meningeal surfaces and considers that the origin of the central nervous system, adrenal medulla and skin is from the same embryologic anlage, one is even more prejudiced to the meningococcus theory.

#### DIAGNOSIS

If treatment with adrenal extracts and sodium chloride proves to be of value in the Waterhouse-Friderichsen syndrome, it will be necessary to distinguish this condition from the rapidly fatal, acute, fulminating cerebrospinal fever. The differentiation may be difficult. The symptoms of adrenal failure and the relatively negative spinal fluid observations are the points on which diagnosis must be made, and even these may be masked or changed. It is known that at least some acute meningitides begin as an invasion of the blood stream and that some fulminant meningococcemias show meningeal localization before death. Indeed, some writers believe that all cases of meningococcemia would go on to a purulent meningitis were it not for the intervention of death.

Differentiation from other conditions should not be difficult. The differences in courses should save the traumatic adrenal hemorrhage seen following birth injuries and purpuras of varying etiologies from confusion with it. Out of eleven cases of adrenal hemorrhage that came to autopsy at the Willard Parker Hospital, death was caused in four by toxic diphtheria, in two by the Waterhouse-Friderichsen syndrome, in two by scarlet fever, and in one each by anterior poliomyelitis, meningitis (*Streptococcus hemolyticus*) and pneumonia.

#### PROGNOSIS AND THERAPY

The prognosis of the disease has, to date, been universally fatal. The duration is rarely longer than twenty-four hours. In a few cases, death has terminated the disease after forty-eight hours. In each of these cases, hemorrhage into one adrenal only is recorded. Therapy, of course, must at this time be largely theoretical. If a rapid loss of sodium ion from the blood stream, followed by fluid depletion, is a result of the adrenal destruction, it would seem rational to replace these elements as rapidly as possible. This could best be done by intravenous injection of sodium chloride solution. It would be interesting to note the effect of large doses of adrenal cortex extract and, since epinephrine seems to increase the potency of cortical extract in adrenalectomized animals, it would seem advisable to administer this drug also. The intravenous use of large doses of antimeningococcus serum would seem consistent with the best principles of treatment. If the infection might be combated with serum, and sodium chloride, fluid, cortical extract and epinephrine given to replace the loss resulting from adrenal failure, and supportive treatment carried out with blood transfusions and intravenous dextrose, it is not inconceivable that some of these patients may in the future be saved.

#### SUMMARY

The Waterhouse-Friderichsen syndrome was first accurately described in the literature in 1901. Since that time it has been recognized in England and Germany as a disease entity. The symptomatology includes sudden onset, malaise, restlessness, and often

gastro-intestinal symptoms. These are followed shortly by lethargy, which rapidly deepens into coma. High fever, weak, rapid pulse, intense cyanosis and purpuric hemorrhages into the skin are characteristic. The disease is usually fatal in from sixteen to twenty-four hours. Massive, bilateral adrenal hemorrhage is the most common postmortem observation. The etiology is probably a fulminating meningococcemia. Suggested therapy includes adrenal cortex extract, epinephrine, sodium chloride, fluids, antimeningococcus serum, dextrose and transfusions.

Foot of Fifteenth Street

## CONGENITAL BONY TEMPOROMANDIBULAR ANKYLOSIS AND FACIAL HEMIATROPHY

REVIEW OF THE LITERATURE AND REPORT  
OF A CASE

LESTER W. BURKET, DDS

Member of the Dental Study Group, Yale University School of Medicine  
NEW HAVEN, CONN.

Bony or fibrous ankylosis of the temporomandibular joint is not a clinical curiosity, but a bony ankylosis of this articulation occurring in the new-born associated with maxillary and mandibular hemiatrophy is of sufficient rarity to warrant a report.

### REVIEW OF THE LITERATURE

Numerous cases of bony intra-articular temporomandibular ankyloses, discovered in the early years of life, have been reported.<sup>1</sup> In all instances in which the ankylosis was discovered within the first year of life or even in those instances in which it was discovered later without a definite history of postnatal trauma there was a history of a difficult forceps delivery. Langenbach,<sup>2</sup> prior to 1903, reported a case of bilateral bony ankylosis resulting shortly after a difficult forceps delivery. At the sixth year of life, arthroplasty was performed and a satisfactory functional result was obtained. Ballantyne<sup>3</sup> cited several cases of hemiatrophy of the mandible and maxilla and stated that this anomaly was often accompanied by ankylosis of the temporomandibular joint, however, no actual case of temporomandibular ankylosis is reported in this complete work. Brash<sup>4</sup> reported a case of facial hemiatrophy with malformation of the ear, but no mention is made of any temporomandibular joint involvement. Canton<sup>5</sup> saw a child, the sixth of eight normal children, who presented atrophy of the left side of the face, the maxilla and mandible all being involved. The ear was malformed, and the usual auditory canal was replaced by two small fistulas.

### ETIOLOGY

The etiology of temporomandibular ankylosis is generally ascribed to infection or trauma. Bony ankylosis has been known to result from otitis media, dento-

alveolar abscesses and complications following scarlet fever,<sup>6</sup> gonorrhea, and even typhoid, in the majority of cases, however, trauma was the direct etiologic factor. Ivy<sup>7</sup> believed that the so-called congenital ankylosis was usually the result of traumatic injuries received at birth and should not be regarded as a true congenital abnormality. Brophy<sup>8</sup> in his extensive work on oral surgery failed to mention the existence of such a condition, nor did Arlow<sup>9</sup> or Gladstone.<sup>10</sup> Blair<sup>11</sup> believed that the so-called congenital ankylosis was "very unusual" and when present was due to trauma shortly after birth or during delivery. He believed that at first a false ankylosis or fibrous connective tissue fixation occurred which then became partially converted into osseous tissue, or that by the use of the forceps in delivery the base of the cranium was fractured in the region of the temporomandibular joint and ankylosis thus resulted. In my opinion, ankyloses arising from birth injuries are not in the true sense of the word congenital.

### PATHOGENESIS

Hemiatrophy of the mandible and maxilla must be carefully distinguished from hypoplasia or interference of growth of the mandible resulting from early ankylosis. The hemiatrophy of the mandible and maxilla found at birth is more likely explained on a trophic basis, whereas that occurring after birth is explained on a dysfunctional basis. Postmortem studies<sup>12</sup> of a patient with progressive hemiatrophy of the face commencing at 12 years revealed definite changes in some of the nerve fibers supplying the aforementioned structures. Underdevelopment of the maxilla and mandible and ankylosis of the temporomandibular joint might be explained by pressure, amniotic or otherwise, acting on the region of the first branchial arches causing arrest of development of the parts formed from this branchial segment. This is evidenced in a case reported by Ogston,<sup>13</sup> in which a unilateral hemiatrophy of the mandible was associated with failure of development of the auditory structures also derived from this arch.

### DIAGNOSIS

Unexplained cyanotic attacks<sup>14</sup> or inability or difficulty in normal nursing may be the first indication of this condition. With bilateral bony ankylosis the mandible cannot be moved, but with a unilateral ankylosis a slight degree of movement or sense of movement is often experienced on examination. Diagnosis is usually made on the basis of developmental inequality of the two sides of the face if the condition is of long duration. In all cases a roentgenologic examination is necessary for the establishment of the diagnosis and to determine the extent and location of the bony union if one exists. Immobility of the mandible in itself is not pathognomonic of bony ankylosis.

## TREATMENT

Temporomandibular ankylosis was the first condition to direct the surgeon's attention to the necessity for arthroplastic intervention. Excision of the head and neck of the condyle was first performed by Professor Humphrey of Cambridge in 1856.<sup>15</sup> Wilms established a joint in front of existing cicatricial tissue in 1858. Verneuil<sup>16</sup> in 1860 performed an arthroplasty of the temporomandibular joint and even interposed a flap of the temporal muscle and fascia between the bony fragments. Helferick in 1893 reported several successful cases, although he interposed only muscle tissue between the fragments. Osteotomy of the body or ascending ramus of the mandible was attempted. While the operation was less difficult, the functional results were far inferior to arthroplasty as near the joint itself as possible. In 1915 Ricket and Schmidt, who had previously employed ivory joints, used a skin flap to keep the bony fragments separated. Brophy used a method partaking of both osteotomy and arthroplasty, introducing gutta percha between the bony fragments which, in the few weeks time this tissue was allowed to remain, served to form a hygroma. The gutta percha was usually removed after four weeks. Ivy, Blair, Murphy<sup>1</sup> and Lyons<sup>17</sup> have all modified and added minor refinements to the original operation of Verneuil, which is today the accepted method. The different operations vary principally in the type of incision employed and the exposure of the joint obtained.

Perhaps no other arthroplasty operation is as successful as that of the temporomandibular joint. The component parts of the newly formed joint are firmly held in position by the scar tissue and the strong muscular sling formed by the masseter, internal pterygoid and other masticatory muscles. Even functional stress applied to the joint during mastication may be lessened by the presence of food between the teeth. Even when arthroplasty is delayed for many years the results are striking, and apparently the ankylosis of one side of the jaw produces no pathologic changes in the uninvolved one. Cruveilhier, cited by Brophy, reported the case of a woman, aged 89, who had had an ankylosis of the left temporomandibular joint since she was 1 year of age. The right joint functioned satisfactorily after operation, although it has been immobilized for eighty-eight years.

Ankylosis occurring in the first few years of life, provided sufficient nourishment can be obtained, is best treated after 6 years of age, at which time the cooperation of the patient, so essential to a satisfactory functional result, can be perhaps earliest secured. Moreover, the first permanent molars are usually erupted at this time, enabling the placing of an orthodontic appliance to stimulate development of the small mandible. Reeducation of speech may be necessary, but this is usually accomplished within two months after operation, provided no other abnormality is present.

## REPORT OF CASE

A woman, aged 27, had given birth to three children, the first two being normal and the third child having clubbed feet and other developmental abnormalities the nature of which were unknown. It died at 1 month of age. The Wassermann reaction of the mother was negative.

She was admitted to the New Haven Hospital Oct 16, 1934, because of labor pains which had begun the preceding night and disappeared during the day, to reappear in the evening. The expected date of delivery was October 28. There were no pains after noon of the day of admission. A medical induction of labor was begun October 17 with castor oil, quinine and 1 soap-suds enema, but this failed to produce uterine contractions and the patient was discharged on this day from the hospital.

Labor pains were again experienced November 6, and the mother was readmitted to the New Haven Hospital November 7, at 4 20 p. m. she was spontaneously delivered of a 3,200 Gm boy, the subject of this report. Approximately 3,500 to 5,000 cc of amniotic fluid escaped after the membranes ruptured. At birth a malformation of the left side of the face was noted.

On closer examination it was noted that the left side of the face below the zygomatic arch was sunken and no superior border or ascending ramus of the mandible could be felt, nor could the left temporomandibular joint be palpated. The horizontal ramus of the mandible was present but rudimentary. The jaws were in apposition with only a cracklike aperture between the maxilla and the mandible on the right, but on the left the soft tissues were continuous between the two jaws, beginning at a point 1 cm to the left of the midline. The right half of the jaws could be separated with a tongue depressor for about 0.5 mm. The left eye and facial muscles did not move. Just anterior to the left ear was a small pedunculated wart-like growth. Small portwine spots were observed on the cheek and other portions of the body. Roentgenologic examination of the abnormality revealed general aplasia of the left ascending ramus and condyle of the mandible. The left temporomandibular joint could not be definitely visualized.

November 8 the infant was taken to the operating room. The face was prepared with soap, water and 5 per cent solution of trinitrophenol. The lateral portions of the upper and lower lips were infiltrated with a small amount of procaine hydrochloride. Silk traction sutures were placed in them to facilitate exposure of the oral cavity. Examination of the maxilla and mandible at this time revealed fusion of the left alveolar processes from a point 1 cm from the midline to the retromolar area. A diathermy needle was used to transect the soft tissues, but it was further necessary to use a small chisel to separate a number of bony trabeculae which joined the alveolar processes. When these were separated it was possible to open the child's mouth almost 1 cm, and the condylar movements were felt to be practically normal. The tooth bud of the lower left deciduous canine was exposed during the operation and removed. There was no extensive bleeding. The infant stood the procedure well.

November 9 a slight depression was noted in the left supra-orbital ridge and the left eye appeared half closed. On the 14th a distinct but slight muscle weakness was noted of the lower facial muscles on the left. The left eye was never opened as widely as the right. November 16 a distinct difference in the size of the pupils was first noted, the right pupil always being larger than the left even in bright light. There were no recorded observations prior to this date on the size of the pupils. The left ear drum was examined but no abnormality was noted. By December 12 the mandible could easily be opened 2 cm. A slight enophthalmos was observed on the left and Horner's syndrome was suggested. The patient was then discharged from the hospital and was not seen until Jan 9, 1935, when he was readmitted to the outpatient department with the jaws again firmly fused. At this time no movement of the mandible could be obtained, but an anterior cleft approximately 0.5 by 3 cm remained through which adequate nourishment could be obtained.

It was decided to postpone operative procedures until the child was 5 or 6 years old, unless feeding difficulties necessitated an earlier operation. The patient was again discharged January 29 after a period of observation, to be followed through the outpatient department.

The patient was again seen February 27, when there was a definite Horner's syndrome on the left. He was brought back again May 13, with a complaint of difficulty in feeding. At this time the upper and lower left first incisor teeth were erupting, the right centrals were not visible through the mucous membrane. The right pupil failed to react to light, remaining dilated at all times. Roentgenograms failed to indi-

cate clearly the exact point of ankylosis nor could the left temporomandibular joint be satisfactorily visualized August 27 all the upper and lower deciduous incisors were erupted The ankylosis of the mandible and Horner's syndrome remained unchanged

## COMMENT

This particular anomaly is in itself very rare, and this case presented several interesting features Ivy<sup>18</sup> has not heard of a similar case Ogston<sup>13</sup> in his comprehensive discussion of congenital malformations of the lower jaw mentioned that bony ankylosis is often associated with congenital hemiatrophy of the face but did not cite any case Brophy<sup>5</sup> stated that in a larger number of cases of congenitally small mandibles there was usually present at birth some degree of ankylosis Numerous cases of bony ankylosis have been reported following in every instance a difficult forceps delivery or an early postnatal trauma It will be remembered that in this instance delivery was at full term and spontaneous Ballantyne<sup>3</sup> stated that the defect may be due to pressure, amniotic or otherwise, acting on the region of the first branchial arch, causing imperfect development or irregular arrangement of the structures arising from this transitory structure Between 3,500 and 5,000 cc of amniotic fluid, a considerable hydramnios, was present in this case The possible effect that the premature labor pains and the attempted medical induction of labor might have had in the production of this anomaly must be considered More fully developed mandibular and maxillary structures have been seen in seven months fetuses than was observed on the side showing the anomaly It would seem likely that the factor responsible for this defect had been acting for some time prior to the premature labor pains This assumption is in agreement with Charles's<sup>19</sup> study on the growth of the mandible

Numerous writers have repeatedly associated progressive hemiatrophy occurring after birth with some trophic nervous disorder Vichow<sup>20</sup> went so far as to call the condition "neurotic atrophy" of the face If one assumes a trophic disturbance responsible for this anomaly, certain discrepancies are evident on an anatomic and physiologic basis Of two large series of cases reported,<sup>21</sup> the majority showed no anhidrosis, no change in the size of the pupils, no difference in the temperature and no unusual growth of hair Likewise no changes in the orbicularis oculi muscles or the quantitative flow of saliva were noted The evidences of atrophy were found in the skin, in the connective tissue and in the fat and bones The muscles, even those supplied by the fifth nerve, were affected only in a minor degree The muscles supplied by the seventh nerve were unaffected Many cases showed marked hemiatrophy of the tongue The skin usually had a glossy appearance characteristic of trophic disturbances

In most of the reported cases the usual syndrome of cervical sympathetic ganglion injury was not present, and in Bramwell's<sup>12</sup> case no evidence of injury to this structure was observed on postmortem examination He later found an interstitial neuritis of all branches of the fifth nerve most markedly the second division The motor and sensory ganglions and the descending root of the fifth nerve were unaffected No changes were observed in the twelfth nerve A peripheral neuritis was observed about the radial nerve Bramwell

believed that the pathologic changes found in this case did not satisfactorily explain the hemiatrophy

The subject of this report showed undoubted evidence of a typical Horner's syndrome, as shown in the accompanying illustration This suggested that a trophic dysfunction might be responsible for the hemiatrophy at birth However, it was not later reflected in the dental development, as the deciduous incisors on the affected side erupted prior to those on the unaffected side and within the normal eruption time for these teeth

A case of hemihypertrophy, as contrasted to atrophy, has been observed<sup>22</sup> in which at birth all the structures of the involved side, including the tongue, showed a precocious and excessive development The right lower permanent incisors and right first permanent molars erupted at 3 years of age and were larger than normal At 6 years the corresponding teeth on the other side of the face were just erupting or were not visible

Infant at age of 5 weeks

A trophic disorder occurring late in the development of the infant might not produce changes in the size of the temporary teeth, however, one would expect delayed eruption of these teeth which was not present in the case reported It must be remembered that in a disease such as congenital syphilis, for example, with its constitutional implications, the deciduous teeth are rarely involved Therefore it is perhaps too early to make any definite statement concerning the dental structures in this case<sup>23</sup>

As regards the mode of therapy in this particular case, it is possible that reankylosis could have been prevented by the insertion of a fascial or muscular slip between the bony fragments In adults, ankylosis has been found almost always to recur when tresser or muscle is not placed between the fragments in spite of the best cooperative efforts of the patient

Provided adequate nutrition can be maintained, further operative procedures are not contemplated until the patient is 5 or 6 years old, when an arthroplastic operation will be performed. Orthodontic treatment will then be practical and will aid in stimulating further development of the ankylosed side of the face and in correcting the asymmetry.<sup>24</sup>

## SUMMARY

A full term spontaneously delivered male infant showed true congenital bony ankylosis in the region of the left temporomandibular joint and alveolar ridges associated with maxillary and mandibular hemiatrophy. Labor was not abnormal, but a moderate hydramnios was present. Lysis of the fibrous and bony fixations was performed twenty-four hours after birth, which permitted fairly normal mandibular movements. Bony ankylosis recurred in two months, however, a sufficient anterior aperture remained to permit adequate feeding. No report of a similar anomaly has been discovered in the literature.

## GLOSSODYNIA

SHERMAN F. GILPIN, M.D.

Fellow in Neurology the Mayo Foundation

ROCHESTER, MINN.

A discussion of the symptom known as glossodynia is of academic rather than practical importance, from the standpoint of the physician, because such cases are rather infrequently seen. A search of the records of the Mayo Clinic reveals only forty-eight such cases. From the standpoint of the patient the disease is of utmost and paramount concern, however, as it is most distressing and incapacitating. This may be attributable to the fact that this symptom predominantly affects people whose threshold for pain is relatively low. Because of the extreme distress incident to the condition, because of the inadequacy in coping with it, and to stimulate interest in the subject, an attempt has been made to determine, if possible, some of the factors in its etiology and the means by which some patients have obtained relief, as well as any other information pertinent to the problem.

When one attempts by a perusal of the literature to obtain some knowledge of this subject one is struck by the paucity of material. Oppenheim<sup>1</sup> in his textbook of nervous diseases devotes only a small paragraph to the condition. Throughout the literature a like neglect is evident. Many articles purporting to consider diseases of the tongue make no mention of the various functional disorders. This is not surprising, of course, since neurologic diseases in general are looked on with indifference by many members of the medical profession.

Among the earliest references to glossodynia were those of Buisson<sup>2</sup> in 1854, Schwimmer<sup>3</sup> in 1886 and Magitot<sup>4</sup> in 1887. Butlin and Spencer<sup>5</sup> in their epochal work on the diseases of the tongue devoted considerable space to this disorder and mentioned as

the causes (1) a neuropathic disposition, (2) dyspepsia or a gouty diathesis, and (3) infection producing reflex burning or pain. Oppenheim gave the best consideration from the neurologist's point of view, he described the disease as

paresthesia, particularly a burning and prickling sensation on the tongue extending perhaps to adjacent membranes. It may be continuous, paroxysmal, and may even disturb the sleep. It has been observed particularly in women of advanced age but is not very common. The teeth were almost always absent, a neuropathic predisposition is generally present, a gouty diathesis may also tend to cause it, cancerophobia is often present. Often it cannot be decided, however, whether hypochondriasis evoked the paresthesias or vice versa. Nothing is found on examination. It is a persistent disorder and may be an initial symptom of tabes dorsalis and of dementia paralytica. Similar disorders may occur elsewhere. I observed a urethrodynia in one of my patients. Glossodynia should not be confused with xerostomia. The treatment is a psychic one. Local treatment by cocaine, silver nitrate and so on may be recommended. Electricity may also be tried.

Sluder<sup>6</sup> in 1918 offered the opinion that lingual tonsillitis plays a causative part in painful tongue or glossodynia. Dean<sup>7</sup> in 1922 and Sluder<sup>8</sup> in 1923 wrote of the relief of the disease by cocainization of the nasal, sphenopalatine or Meckel's ganglion. Dean's patient was apparently permanently relieved by injection of 95 per cent alcohol with 5 per cent phenol into the ganglion.

Engman<sup>9</sup> in 1920, in reporting a group of twelve cases, attributed the symptom to a fear of carcinoma. All his patients were considered to be psychoneurotic and all of them had an intense fear of carcinoma. His therapeutic suggestion was contained in one word, "reassurance."

Beall<sup>10</sup> in 1922 reported four cases in which he felt that the condition was dependent on faulty diet. Two of these patients recovered when milk, cream and meats were added to their diets. He raised the question as to whether these were cases of early pellagra and he also felt that the condition was the result of a diet poor in protein. In the discussion of his paper, mention was made of relief obtained in two cases by the administration of hydrochloric acid and in three others by the administration of alkali.

McPhedran<sup>11</sup> in 1927 reported six cases of glossodynia. In four of these cases the patients were past the menopause, and all his patients were of a nervous temperament. All had had repeated serious illnesses and half of them also had undergone major operations. All presented themselves because of lingual symptoms. In none of these cases could there be found anything objective on examination. All were living under high nervous tension and reported that excitement, worry and loss of sleep accentuated their discomfort. Any improvement seemed to result from improvement in general health.

Marshall<sup>12</sup> in 1928 drew attention to the papillae foliatae, a row of small vertical projections of mucosa

on the sides of the tongue immediately anterior to the attachment of the palatoglossal folds. These, he said, have no pathologic significance and yet, when discovered by the patient, may cause grave worry.

Seller<sup>13</sup> in 1928 commented on cases in which burning tongue was associated with hyperacidity. He recommended alkalis and a suitable diet as the proper treatment. He postulated that the burning is a reflex from the stomach, by way of the vagus nerve to its nucleus in the floor of the fourth ventricle, and thence to the nucleus of the trigeminal nerve and down the latter nerve to the tongue.

Morelli<sup>14</sup> in 1929 confirmed Seller's observations and called attention again to the relief incident to alkaline and dietary therapy. He confirmed also a further observation by Seller that, by producing a moderate hyperacidity, he could bring on the symptom of burning tongue and likewise relieve it by the administration of alkalis and by regulation of the diet.

Michael<sup>15</sup> in 1931 again called attention to the cancerophobia that is "usually present." He found the pain to be constant or inconstant, as the case might be, with a duration varying between months and years, and with periods of freedom for as long as several months. As to etiology, he mentioned, first, a psychoneurosis, second, local causes, such as artificial dentures, third, hypo acidity or hyperacidity, and, fourth, pernicious anemia. He felt that local applications are of little avail. In the discussion of this paper, mention was made of myxedema as another cause of burning tongue.

Montgomery and Culver<sup>16</sup> in 1932 found that the date of onset is usually not known. They found also that in half of their thirty-two cases a change of appearance in the tongue was noted at the site of burning, that is, the papillae were enlarged and reddened or purple. Their patients characteristically drew attention to this change. These writers mentioned reflex causes from the digestive tract, tonsils and teeth, mechanical causes from rough teeth, the effects of sweets and fruits, and the abuse of the use of tea or coffee as possible etiologic factors. They felt that smoking had no effect.

As had been mentioned previously, this group of patients seen at the clinic numbered forty-eight. As others have found, the majority of sufferers were women, thirty-seven of the forty-eight patients seen at the clinic were women. Of the whole group, thirty-five, or nearly three fourths, were more than 50 years of age. The average age of the whole group was 54.3 years. The ages of the male patients varied between 27 and 73 years, and the ages of the female patients varied between 20 and 72 years. There was a larger percentage of the female patients in the upper age group than the opposite sex showed.

Because one or two writers have felt that there was some connection between migraine and glossodynia, I have attempted to determine the incidence of the former disease in this group of cases. Only ten of the forty-eight patients, or, roughly slightly more than a fifth of the group, gave a history of migraine. At first glance, this is a seemingly low incidence as the proportion of individuals in the general population who suffer from migraine is considerably greater. When one con-

siders, however, that nearly 75 per cent of the patients in this series of cases were past 50 years of age, the seeming discrepancy is understandable for, as is well known, migraine tends to disappear after the age of 50 years. No connection, therefore, could be determined between these two conditions.

Another factor which it seemed reasonable to suppose might be a powerful etiologic agent is that form of mental disturbance known as depression. The frequency with which patients suffering from affective disorders are liable to be hypochondriac and to suffer from somatic delusions made this supposition sound very tenable. It was interesting, therefore, to note that only five of the forty-eight patients could reasonably be classified as being depressed, nevertheless, the incidence of mental depression is higher among those who suffer from glossodynia than it is among the general population.

As one goes over the history of cases in which glossodynia has been the diagnosis one obtains the impression that, in addition to the fact that the patients are generally individuals who are well up in years, some of these patients have signs of definite sclerosis of the cerebral vessels. This is an impression which also has been gained by many neurologists of wide experience. In eleven of these forty-eight cases there was evidence of arteriosclerosis of the central nervous system. Here again, therefore, is another possible factor in the production of glossodynia.

As mentioned previously, certain writers have felt that there is a connection between the gastric acidity and glossodynia. In the sixteen cases in which gastric analysis was performed, the values for the gastric acidity were normal. In five other cases the values for the free hydrochloric acid in the stomach varied from 8 to 16, according to the method of Topfer. An acidity was present in only three cases, and in only one of these cases was there any anemia whatever. This was the result of an extensive carcinoma of the stomach. Four years after examination another patient who had achlorhydria, reported that the burning was still present but that many other symptoms, which included burning in the rectum and vagina had abated. There was no reason, therefore, to think that pernicious anemia had developed. In the third case, in which hydrochloric acid was absent from the gastric secretion, the patient reported two years after her first visit to the clinic that her tongue was no better. She failed to mention any other symptoms present at the time of writing the letter. It is needless to say that the appearance of the tongue is widely different in glossodynia and in pernicious anemia.

Cancerophobia has been indicted by one writer as the cause of glossodynia. It so happened that this fear was present in all of his twelve cases. A comparable relationship was not found in the group of cases under consideration. Only eight of the forty-eight patients expressed this fear which in some cases amounted to a phobia and it is difficult to determine whether this fear or the burning came first. A few seemingly had acquired the burning first. One of these also had a dread of pellagra. Two patients had a fear of syphilis, which played a very active part in their histories. This small incidence of patients who have the intense fear of carcinoma known as cancerophobia is worthy of emphasis. Most of the writers comment on the extremely high percentages of individuals so afflicted.

Another point which most writers have felt worthy of mention is the condition of the teeth. Most patients

whose tongue, palate or mucous membranes are the seat of a burning discomfort have of course, had their teeth examined. As so often happens in other conditions, doctors and dentists advise extraction rather frequently on empirical grounds in these cases. Consequently, it was not surprising that of the forty-eight patients in this series twenty had lost all or many of their teeth. Twelve of the twenty were completely edentulous. Twenty-one still retained the dentures with which nature provided them. In seven cases no record of dental examination was noted.

I will now consider what is perhaps the most significant aspect of this discussion, namely, the neuropathic predisposition. Thirty-seven of the forty-eight patients complained of various functional disorders, in addition to the glossodynia. When a physician designates a symptom as functional, he lays himself open to a possible considerable amount of criticism. He is especially vulnerable because such an opinion is founded on his interpretation of symptoms voiced by the patient whose understanding of the same words may be entirely different. This is especially true when symptoms are vague and hard to describe. Be that as it may, it is assumed and maintained, although with not too great certainty, that thirty-seven of the group were psychoneurotic individuals whose many and varied symptoms classified them as such from the outset. These other neurotic symptoms included burning of the legs, continuous headache, a drawing sensation from the stomach to the rectum, continuous pain in the cheek, generalized aching of long duration, burning in the vagina and rectum, a feeling as of a lump in the throat, discomfort in one apparently normal tonsil, and the taste of pus in the throat. Gastro-intestinal symptoms, presumably functional, also should be mentioned with this group.

Perhaps one of the best evidences of the fact that glossodynia is a psychoneurotic manifestation is the way in which some of the patients report that they received relief from their distress. One woman, while still at the clinic, received treatment for varicose veins. She had had a bitter taste, and burning in her mouth, tongue, pharynx and nose, for two and a half years. When the doctor injected a drug into one of her veins, she said that she collapsed and feared that she was "gone." The doctor then injected something in her arm and she recovered. By the time she reached her hotel room, the burning in her tongue was gone and at the time that she replied to our letter of inquiry, two years following her visit to the clinic, she still had had no return of the glossodynia.

Another patient reported that no physician had been able to help her. She, however, finally hit on the scheme of chewing spruce gum, for which she sent half way across the country. This form of therapy, surprisingly enough, resulted in complete relief of her pain. These instances, it seems, are fairly strong evidence that suggestion was the significant factor in the treatment and, as such, could only have resulted in relief of a condition which was psychogenic in origin.

Through subsequent visits to the clinic or letters of inquiry, it was possible to learn further about the course of the disease in twenty-five cases. Of the twenty-five cases, complete recovery was reported in eight. Five other patients felt that they were somewhat better than they had been. Three others had found that they had discovered the cause of their discomfort. Thus, one man reported that as long as he refrained from smoking he had no burning, another

patient, a woman, could avoid the burning by excluding starches from her diet. Still another woman had found that by eliminating strawberries, rhubarb, pineapple and highly seasoned foods she, too, was free from the pain. The rationale of this is none too clear, since the glossodynia had been continuous. In nine of the twenty-five the condition was either worse or not better. One of the patients had experienced relief following the extraction of her upper teeth. Another found that by holding some chewing gum or a piece of slippery elm bark in her mouth she could obtain partial abatement. Still another individual, on a subsequent visit to the clinic, made no mention of the burning, and this apparent recovery was perhaps the result of the fact that a pain in the face, which she had complained of coincident with the burning tongue, had become worse. It was therefore probably a case of the one distress overcoming perception of the other. One patient, on a second visit to the clinic, reported that a chiropractor had relieved her burning tongue. Several apparently improved without any treatment except reassurance, encouragement and the passing of time.

As to the duration of this condition, the figures in this group are somewhat unreliable for the reason that, as Oppenheim has pointed out, the date of onset is rather vague in the minds of most of these people. In only eight of these cases could the duration be even approximated. The longest duration was nineteen years and the shortest two years. In five of the eight cases the condition had been present approximately two years.

Finally, it should be emphasized that in none of these cases were there found any local or general positive physical manifestations except for an occasional bad tooth and achlorhydria, which was present in three cases. The burning in this series involved the tongue and the mucous membrane of the mouth, cheeks, lips, pharynx, palate and even of the nose. The discomfort included not only burning but such sensations as a metallic or bitter taste in the mouth, prickling, sticking, an acid taste, and a feeling as if a hot iron had been placed on the parts affected.

#### SUMMARY AND CONCLUSIONS

The following points seem worthy of final iteration. More women are affected than men, and the disease has its onset more frequently beyond the age of 50 years. There is a high incidence of other psychoneurotic symptoms accompanying this manifestation. A fair proportion of patients also suffer from arteriosclerosis of the central nervous system and a small proportion suffer from depression coincidental with this burning, painful tongue. Cancerophobia is present in a few cases. The teeth have been removed in approximately half of these sufferers. Complete relief may be expected in about a third of such cases and partial relief may be expected in another third. Relief may result from various forms of psychotherapy alone, as local treatment apparently is of no avail.

---

**The Common Eel**—The common eel of our rivers has its spawning groups in the Atlantic Ocean near Bermuda. Here the eggs are deposited and the young eels hatch and must then swim all the way back to the U. S. to grow up. European eels of the closely related species also visit nearly the same locality to spawn. But somehow the young of the two species sort themselves out—the young of the American species requiring a year to reach home shores, and the other requiring three years to reach England and France.—Bell, F. T. *Fish and Their Management*, *Tells* 1:32 (April) 1936.

OXYGENATION IN RELAPSING  
AMEBIASIS

REPORT OF CASE

MEYER GOLOB, MD

NEW YORK

Though it is a solitary instance, I believe this case presents several features which make its reporting incumbent on me. That amebiasis is a protracted and recalcitrant malady is of negative concern to this discussion, but when recrudescence occurs after a period of veritable clinical arrest the condition assumes a coercive character, calling for a most exhaustive therapeutic armamentarium.

An incidence of only fifty-five cases of amebic dysentery in the population of New York City of more than seven million is insignificant, but a death rate of five out of these fifty-five cases is too high to escape attention. I am of the opinion that it is the delay in proper diagnostic approach which is conducive to ineffective therapy when diagnosis is finally established. When confronted with a doubtful case of mucous colitis, one should treat for amebiasis until the condition is proved otherwise. It is likely that the favorable result reported from the use of antiamebic agents in cases of mucous colitis have occurred in patients who had an undiagnosed amebic infestation. Delay in diagnosis is synonymous, in most cases, with delay in therapy, an accentuated aggression of *Endamoeba histolytica* on the intestinal mucosa, and a host depleted of vigor in a vain effort to combat a harmful dweller in the colonic tract.

The salient points in this case are as follows:

A S, a woman, aged 26, single, was admitted to the hospital Jan 5, 1935, with a diagnosis of hemorrhagic colitis.

The history pertaining to a bowel syndrome dated back to April 1934 when its three months' duration was marked by an elimination frequency of from six to seven times a day. The sanguinous stools were ascribed to the old popular diagnosis of "bleeding piles." A lull in symptomatology followed, but after several months diarrhea recurred. Loss in weight, secondary anemia and asthenia dominated the clinical picture. Nonspecific therapy without clinical amelioration effected her hospitalization. Repeated examinations of the feces revealed the ameba in vegetative and cystic forms.

The conventional specific treatment was instituted. Emetine, injected intramuscularly, was in the vanguard alternating with arsenicals and iodochlorhydroxyquinoline, properly spaced. The response was spectacular. The patient was discharged symptom free, March 8. Careful observation and amebicidal therapy were continued. The patient had enjoyed splendid health when out of a clear sky in the latter part of May the bowel symptom returned in all severity. Acute, fulminating diarrhea gravis was a pertinent and descriptive term for the condition. Proper spacing of arsenicals brought no results. The administration of powdered ippecac root in the form of enteric coated capsules, with at least 40 grains (2.6 Gm) being brought into play at one time, was discontinued because of marked nausea unaccompanied by evidence of efficacy. The patient took a downward course. Two blood transfusions were given with but meager improvement in the general condition. Surgical intervention was hesitantly considered.

At this phase of an obdurate malady I analyzed the facts of the history as follows. With the second admission to the hospital the case was considered as a relapsing stage of chronic amebic dysentery. Diagnosis in such cases in the absence of live motile parasites, is made from the resting or cystic forms. Wet stool specimens disclosed no amebae but cysts were found. The conventional therapy, properly spaced was administered with a progressively worse response on the part of the patient who was literally cemented to the bed pan. The dominating

picture consisted of true anorexia, progressive asthenia and gross emaciation. Depleted resistance was added to a syndrome of nervous depression, resignation and episodes of crying spells.

Amebic hepatitis and amebic abscess were ruled out. Tenderness in the right lower part of the abdomen with no soreness elicited over the liver region suggested a feeding focus of amebic infection. Exploratory laparotomy was suggested in a "nothing-to-be-lost" attitude. Repeated search for tuberculosis and bacillary dysentery yielded negative results. Microscopy of the biliary aspirates (Meltzer-Lyon method) disclosed rare pus cells, a moderate number of red blood cells, many squamous and cuboidal cells, but no amebae. The patient went through this test heroically in hopes of obtaining relief. I was convinced of the inadvisability of repeating the procedure in this case, and questioned the possibility of an anaerobic spore-bearing organism's being the enemy.

A proctoscopic examination brought into view a classic ulcerative picture with profuse bleeding. A barium sulfate suspension enema revealed 'ulcerative colitis and ileocecal incompetence.' With the patient sinking rapidly there was no time for culture study of feces in an effort to establish fine, precisional diagnosis. Empirical therapy, like exploratory laparotomy when diagnosis is obscure, was urgently called for and instituted.

## TREATMENT

High regard must be given to Dr Joseph Felsen<sup>1</sup> for his splendid presentation concerning the use of colonic irrigation with strong oxidizing agents. It occurred to him that "perhaps pure oxygen in amounts sufficient to alter materially the gaseous tension in the intestines might prove more effective and less distressing than the fluid irrigations." The results he obtained by the use of oxygen in idiopathic ulcerative colitis were encouraging. The case under discussion did not come within the definition of the syndrome of idiopathic ulcerative colitis because the parasitology had been well established. We were confronted, however, with a mucopurulent sanguineous exudate in a case of relapsing amebiasis that proved recalcitrant to a varied and specific therapy. Under such circumstances, the end result of pathogenesis deserved all attention—an ulcerative colitis calls for treatment. Colonic irrigation with various amebicidal agents was not only working great hardship on a weary and exhausted patient but had brought about a prolapse of the rectum which occluded the anal ring. All attention was focused on reducing the marked edema of a protruding vulnerable mucosa. Except for symptomatic therapy, all amebicidal agents were discontinued. Careful analysis of the case justified my conclusion that I was dealing with a case of symbiosis of a pathogenic macrobic micro-organism with a harmful parasite. Paulson<sup>2</sup> asserts, in ulcerative colitis, that the term idiopathic precludes the presence of pathogenic parasites. "Yet," he writes, "the simultaneous appearance of amebic dysentery and ulcerative colitis has been claimed to occur as distinct entities in some cases by virtue of the concomitant occurrence of three conditions (1) the isolation of *E. histolytica* (2) the feeling that the etiology of ulcerative colitis has been ascertained, and (3) the presence of types of ulceration seen by rectosigmoidoscopy said to be characteristic for each of these conditions." He reasons, "it would seem to be in error to deviate from the accepted teaching, namely, that the infection by *E. histolytica* be regarded as primary and the involvement of ulcerative colitis as secondary."

The case under discussion presents proof of priority of disorder in the two roentgenologic studies of the colon. During the first attack in January 1935 the

report read "marked spastic colitis" and in August 1935 "ulcerative colitis." Examination of the roentgenograms gave undebatable evidence of primacy of diseases namely, the infection by *Endamoeba histolytica* as primary and the involvement of ulcerative colitis as secondary. Kiefer's<sup>3</sup> study of forty cases of ulcerative colitis is in agreement with Paulson's contention. Kiefer found that 74 per cent of the cases showed a positive Craig test for *Endamoeba histolytica*, and in many of these cases antiamebic treatment yielded favorable results. It is conceivable that the success of ipecac therapy in mucous colitis may have occurred in patients afflicted with unrecognized amebic infection. Paulson is right in his assertion that "etiology and therapy should not be confounded clinically." The art of medicine must often be separated from the science of medicine, and the therapy chosen must be that of most efficiency, regardless of etiology. Ileotomy was considered, but the condition of the patient made such intervention extremely inadvisable. Further, while acute septic symptoms might be relieved, the damaged colon would not regenerate. I therefore chose to treat the case as a secondary ulcerative colitis, based on a mucosa made vulnerable by the ameba, an environment in which even normal colonic dwellers, saprophytes, become violent and pathogenic.

I feared to administer the recommended dosage of oxygen ("seven hours of oxygen per day administered every other hour between 8 a. m. and 9 p. m. provided a gaseous content of approximately 1,750 cc., or almost 2 liters")<sup>1</sup> because the ulcerated areas and copious oozing of blood indicated danger of perforation. We commenced with a dosage clinically comfortable to the patient (shown in the accompanying table) given in alternate hours between 8 a. m. and 8 p. m. Nocturnal administration of castor oil enabled better toleration of the distention caused by the incoming oxygen. No belching was noted. The expulsion of debris, mucus and coagulated blood from the wall of the intestine permitted ready access to the incoming oxygen. No rule as to the duration of oxygenation could be observed, however, dosage and frequency being governed by tolerance of the patient.

The response to oxygenation was spectacular. The patient's appetite assumed an avacious aspect. In

addition to a liberal tray she enjoyed large sandwiches brought by her mother—an act of devotion which was detected and allowed. It is interesting to note that the red cell sedimentation rate receded from 31 mm. to 19 mm. for thirty minutes. Her markedly dehydrated clinical picture improved rapidly. This, of course, might be attributed to intravenous administration of 5 per cent dextrose in physiologic solution of sodium chloride. This therapy is synergistic, but dextrose did not destroy the pathogenic micro-organisms. A heavily coated tongue and offensive breath cleared. Bowel movements became fewer, and improvement in the patient's general condition was marked. Hydrochloric acid

therapy was instituted long before gastric analysis revealed an achlorhydria, on the principle that an inhibited gastric secretion is part and parcel of general debility. The hydrochloric acid was not administered as an antiamebic. The ameba passes through the stomach uninjured by free hydrochloric acid. But a basic part of antiamebic therapy is the strengthening of the general condition of the patient. As a high caloric diet calls for a high hydrochloric acid value, and, as noted, general debility implies low hydrochloric acid or achlorhydria, administration of hydrochloric acid, following a gastric contents test, is indicated in amebiasis.

The patient was discharged from the hospital Aug. 17, 1935, and was placed on vioform.

#### CONCLUSION

A solitary case does not permit the drawing of a definite conclusion. The facts are here presented. The favorable results derived from oxygenation in a justly labeled "colitis gravis" stemming from amebiasis warrant its report. If those who are confronted with similar cases employ colonic oxygenation, case reports and series studies will give cumulative evidence of its therapeutic effectiveness. Survey of the literature disclosed no reference to colonic oxygenation in amebiasis.

Unfortunately the vagaries of the patient's family have prevented a close follow up. The main argument of this report, however, is not that a cure was obtained but that development from tumult to quiescence was achieved by harmless oxygenation of the colonic tract.

## Clinical Notes, Suggestions and New Instruments

### BRADYCARDIA DUE TO SPONTANEOUS HYPOGLYCEMIA REPORT OF A CASE

ALEXANDER PIERCE ORMOND, M.D., AERON, OHIO

The cardiac response seen most commonly with hypoglycemia is an increase in the ventricular rate and in the minute volume.<sup>1</sup> Various degrees of tachycardia are seen quite commonly both in patients who have received an overdose of insulin and in patients with spontaneous hypoglycemia. Harris<sup>2</sup> reports a rather extreme example. His patient at times had a cardiac rate of 200 beats per minute. During one bout of tachycardia it was discovered that her blood dextrose was 56 mg. per hundred cubic centimeters. Administration of dextrose raised the blood dextrose to 84 mg. per hundred cubic centimeters and at the same time dropped her heart rate to normal.

I have not been able to find in the literature any reference to the occurrence of bradycardia with hypoglycemia. Harris<sup>3</sup> stated that although he had not observed bradycardia with spontaneous hypoglycemia, he did recall one diabetic patient in whom bradycardia followed insulin overdosage.

#### REPORT OF CASE

J. A. F., a man, aged 27, had rather frequent colds, and a sore throat every winter until 1929. He had influenza in 1918. Otherwise he had remained well until 1930, when he had two attacks of stomach trouble lasting several weeks. In September 1931 he had a more severe attack and sought the advice of a physician. These attacks were characterized by sour stomach, "heartburn" and the belching of gas, beginning about two hours after meals. There was no pain or nausea. He was examined thoroughly but nothing unusual was found. Gastrointestinal x-ray studies showed nothing abnormal except the appendix.

which was linked, somewhat enlarged at the tip and remained filled at the end of seventy-two hours. The patient stated to me that at this same time he became weak and nervous toward the end of his day's work, his heart fluttered, raced and sometimes seemed irregular in rhythm, and he had several fainting attacks but never bit his tongue. He refused appendectomy, quit his job as clerk in a grocery store, and went to his father's farm. Within two months the symptoms had disappeared and after six months he resumed his work, remaining well for nearly three years. Dec 15, 1934, he began to have epigastric distress, with burning, gnawing and "gas" occurring three or four hours after meals. Relief could be obtained by taking food or sodium bicarbonate. Dec 29, 1934, while at work he had pain in the right lower quadrant of the abdomen. Dr H V Sharp examined him at home, finding some tenderness in the epigastrium and in the right lower quadrant. The temperature was 98.4 F. There was no rigidity, nausea vomiting or abnormality of bowel action. Rectal examination revealed no tenderness. Because the conditions found were atypical and the history resembled that of peptic ulcer, a modified Sippy regimen was prescribed, and the next day all abdominal distress and tenderness had disappeared. Jan 5, 1935, while at work, the patient had a sinking spell and felt faint. When examined, the abdomen apparently was normal but the pulse rate was only 42 per minute. At this time I was called because of the bradycardia. The patient was 66 inches (168 cm) tall weighed 128 pounds (58 Kg), was well nourished and was apparently normal except for infected tonsils, slight internal strabismus of the left eye and a bradycardia of 43 per minute. The heart size and sounds were normal. The blood pressure in millimeters of mercury was 115 systolic 70 diastolic. The attempt to sit erect caused him to become faint, but he was weak, nervous and apprehensive even when lying down. He volunteered the theory that his "nerves upset him." Because of the history of nervousness and fainting, relieved by the taking of food I suspected hypoglycemia and prescribed one tablespoonful of Karo syrup with each feeding of milk and cream. It was not possible to hospitalize him. Two days later, when seen at my office he was enthusiastic about his recovery, stating that he felt better than he had been feeling in months. The pulse rate was 72 per minute the blood pressure was 122 systolic, 75 diastolic. He performed the stair-climbing test (twenty-seven trips over two steps, each 9 inches high, in ninety seconds) without the slightest evidence of distress or faintness. At the end of this

that hour the patient complained of feeling very faint, but his pulse rate was normal. An electrocardiogram taken when his pulse rate was 53 per minute, showed no evidence of myocardial damage or abnormalities of rhythm. The PR interval was at the upper limit of normal, 0.20 second.

A diagnosis of hyperinsulinism was made, the Sippy regimen was discontinued, and the patient was placed on a diet composed of protein 60 Gm, carbohydrate 120 Gm and fat 150 Gm daily, divided into six feedings. He also was given phenobarbital one-fourth grain (0.016 Gm) every four hours. On this regimen the abdominal distress did not return, there was

#### Dextrose Tolerance Test, January 15

Sixth hour	50 mg per 100 cc

no cardiac abnormality and the patient felt perfectly well except under unusual stress of work or worry. Because of the emotional strain connected with his job, in May 1935 he returned to the farm near Birmingham Ala. I referred him to Dr Seale Harris,<sup>4</sup> who wrote "The patient is greatly improved since going on the diet, and came in to see me just because you told him to come." A dextrose tolerance test was made by Dr Harris (curve B on the chart). The pulse rate was 72 per minute. The basal metabolic rate was plus 18 per cent. Dr Harris believes that hypopituitarism may be a factor in his case because of a decline in the patient's sexual powers. The patient wrote me Oct 6, 1935 that he is working again and said "I am following the diet carefully and am glad to say that I am steadily improving and can hold out to do my work real good."

#### COMMENT

This patient probably had an attack of hypoglycemia in 1931 with spontaneous recovery from his symptoms. During that attack he had indigestion, tachycardia and possibly also extrasystoles. His second attack three years later was characterized by abdominal distress simulating that of duodenal ulcer, by weakness by nervousness and by bradycardia.

The cause of this bradycardia is purely speculative. Cannon, Melver and Bliss<sup>5</sup> in 1924 working on cats with denervated hearts concluded that the increase in heart rate during hypoglycemia resulted from a discharge of epinephrine by the adrenal glands in response to some sympathetic stimulation. Ernestine Riseman Stern and Alexander<sup>6</sup> in 1935 found also an increased cardiac output apparently due to the same mechanism. However, when the adrenals were intact the cardiac minute volume decreased and they concluded that hypoglycemia per se has a deleterious effect on the myocardium. Dworkin<sup>7</sup> in 1931 working with unanesthetized intact cats demonstrated that hypoglycemia causes central vagus stimulation as well as sympathetic adrenal excitation the antagonism of these two effects maintaining a relatively constant heart rate.

exercise the blood pressure was 160 systolic 90 diastolic and the pulse rate 80 per minute. After one minute the blood pressure was 135 systolic, 90 diastolic pulse rate 80 after two minutes, the blood pressure was 122 systolic 80 diastolic pulse rate 76. This exercise did not bring out any abnormality of the heart sounds and the results indicate an apparently normal myocardium. The blood count and urine analysis were normal. The blood Wassermann and Kahn reactions were negative. Jan 15 1935 Dr F C Potter performed a dextrose tolerance test using 175 Gm of dextrose per kilogram of body weight (curve 1 on the chart). The Folin and Wu method of blood dextrose determination was used. The third hour value of 21 mg per hundred cubic centimeters was checked because of the unusually low reading and was found to be correct. At

When the patient omitted just one meal there was no decrease in the cardiac rate, but he would have hypoglycemic symptoms consisting principally of nervousness and fatigue for about two hours, followed by a return of euphoria. Inspection of his dextrose tolerance test (curve A) shows the reason near the third hour, when the blood dextrose was low, hepatic glycogenolysis, which the Coris and Buchwald<sup>8</sup> have shown is due to an increased epinephrine secretion, raised the blood dextrose at least temporarily. In order to decrease the heart rate for the purpose of making the electrocardiogram, it was necessary that he refrain completely from carbohydrates for thirty-six hours. During that period he felt constantly miserable, weak and nervous. It is possible that the store of glycogen in the liver was lowered by this starvation to a point at which there could be no increase of blood dextrose from that source, a state of constant hypoglycemia being the result. It is possible also that this constant hypoglycemia caused an overstimulation of the adrenals, with eventual relative exhaustion of the supply of epinephrine. A combination of central vagus stimulation with myocardial depression due to the hypoglycemia evidently overbalanced the antagonistic sympathetic-adrenal effect, bradycardia being the result. Theoretically this may have been due to a lowered output of epinephrine.

#### VIABILITY OF SPERMATOZOA IN THE CERVICAL CANAL. PRELIMINARY REPORT

FRANCES I. SEYMOUR, M.D. NEW YORK

This is the report of an interesting observation that I made on the viability of a specimen of semen obtained from a donor and introduced into the cervical canal of five different patients on the same day by means of a cannula.

It is interesting because a great deal of work has been done on the  $pH$  of cervical secretions, and the variation of the  $pH$  in the cervical canal. I refer to cases other than those infected with such conditions as gonorrhea, confining my reference to these five cases presenting normal healthy cervixes.

Dec 10, 1935 five patients were artificially inseminated from one donor. The semen was deposited by a cannula against the internal os. The uterus was not entered and very little pressure was used during insertion so as to avoid any forcible opening of the internal os. In cases 1 and 2 there were large cervical plugs of mucus presenting at the external os. These were left in situ. The cannula was introduced between the cervical plug and the cervical wall. A tenaculum forceps was used to straighten the canal. About 0.1 cc was used in each case after the specimen had been well shaken. Daily examinations were made of all five patients and a sterile earloop,

#### State of Viability of Spermatazoa in Five Cases of Artificial Insemination

Case No.	Dec 10 3 hrs	Dec 11 40	Dec 13 60	Dec 14 110	Pregnancy Obtained
1	Very active	Dead			Pregnant
2	Very active	Sluggish	Sluggish	Dead	Pregnant
3	Dead				None
4	Very active	Active	Sluggish	Sluggish	Pregnant
5	Sluggish	Sluggish	Dead	Dead	None

small size was introduced and withdrawn and the fluid examined microscopically. The observations are recorded in the accompanying table.

The pregnancies were ascertained by the Friedman test in conjunction with the usual examination and symptomatology.

These inseminations were made on the twelfth day after and including the first day of the patient's period so that in case 4 the spermatozoa were still alive on the sixteenth day.

Patients 3 and 4 had been inseminated the previous month with semen from a different donor, which had not caught. In

each instance the spermatozoa were dead on the forty-five hour examination done at that time.

The spermatozoa of the donor used in the test referred to herein have the greatest viability in the cervical canal of any donor so far recorded. As brought out in the table, at the 110 hour examination, on the fifth day, the spermatozoa were alive in case 4 and were still attempting to penetrate some pus cells that were introduced on the slide. Their movements were sluggish but there was life.

## Therapeutics

### THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.

CHICAGO

NOTE—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The articles will be continued from time to time in these columns. When completed, the series will be published in book form.—Ed.

#### THE THERAPY OF NONTUBERCULOUS LUNG ABSCESS

IN COLLABORATION WITH DR. RALPH BOERNE BITTMAN  
Associate Professor of Clinical Surgery, Rush Medical College  
University of Chicago

The symptoms, clinical course and physical manifestations of lung abscess point to two diverse methods of origin. The first occurs as a result of the blocking of a bronchus by an infected clump of material, the second as a result of an infection in the interstitial pulmonary structure. The first might be called a bronchial abscess, the second an interstitial abscess. A large number of lung abscesses arise as a combination of the two conditions, but usually one form or the other, that is, the bronchial or the interstitial, predominates.

A classic form of bronchial abscess is the one arising shortly after some operation on the upper air passages. This abscess is usually situated in the right lower lobe, is accompanied sooner or later by copious expectoration, and roentgen examination discloses a more or less circular opacity with a well defined fluid level in it.

The classic form of an interstitial abscess is the one secondary to some generalized infection elsewhere in the body or in the lung itself. It may be situated in any part of the lung fields. The early roentgenogram shows a hazy irregular opacity without a fluid line. (It is taken for granted that all chest plates are taken with the patient either in the upright position or lying on his side.) The patient usually has a high fever. There may be no sputum or, if sputum is present, instead of being foul smelling and purulent it is odorless and mucoid. Sooner or later such an interstitial abscess usually breaks into a bronchus. After bronchial drainage has been established there is usually an improvement in the general condition of the patient, the temperature falls, and the sputum becomes copious and foul.

For the sake of therapy it is best to subdivide lung abscesses into the acute and chronic forms. An acute lung abscess is one of recent origin and, excepting for an occasionally well situated bronchial abscess that can

<sup>8</sup> Cori, G. T., Cori, C. F., and Buchwald, K. W. Mechanism of Epinephrine Action. Changes in Liver Glycogen and Blood Lactic Acid After Injection of Epinephrine and Insulin. *J. Biol. Chem.* 86: 375-388 (March) 1930.

be reached by the bronchoscope, it cannot be treated specifically. A chronic abscess, on the other hand, is one in which the pathologic changes have been fairly well established and, in this form, surgical treatment can often be successfully applied.

#### DIFFERENTIAL DIAGNOSIS

These forms of lung abscess must be differentiated for purposes of treatment from

(a) *Tuberculous cavity* If a tuberculous cavity is present, tubercle bacilli will always be found sooner or later on repeated examinations of the sputum. Continued absence of these organisms points in favor of a nontuberculous cavity. In addition, physical and x-ray signs of tuberculosis are much more apt to be found in the apex and on both sides of the lung. Pulmonary abscess is more usually limited to one lobe, most commonly the right lower lobe.

(b) *Bronchiectatic cavity* Contrast medium x-ray examination will differentiate a bronchiectatic cavity from an abscess, for in the former condition the cavity becomes well outlined by the adventitious shadow while the contrast medium seems to avoid a lung abscess, so that the dense contrast medium shadow will usually be outside the lung abscess shadow. It may even be surrounding it.

(c) *Carcinoma cavitation* When a patient of "cancer age" develops signs and symptoms of lung abscess without the history yielding the usual etiologic factors for the development of lung abscess, carcinoma must be thought of. The same principle applies to empyema, which is also not infrequently a sequel of thoracic carcinoma. The differentiation is made by roentgenography and bronchoscopy.

(d) *Abscess due to aspiration of foreign body* This is also suggested by the history and the diagnosis made by roentgenography and bronchoscopy.

#### PROPHYLAXIS

Prior to operations on the mouth and pharynx, the best possible oral hygiene should be employed. Disease of the teeth and the gums should be taken care of in a routine manner, and an antiseptic mouth wash, such as the Antiseptic Solution of the N. F. VI, should be used as a routine.

During tonsillectomy the following precautionary measures will help to prevent lung abscess: anesthesia below the point of abolishing the cough reflex; keeping the head lower than the body; keeping the pharynx clear of mucus and blood by means of a suction tube; and prompt ligation of all bleeding vessels.

Following operations of any kind, aspiration of vomitus must be prevented by constant attendance of a nurse until the patient can clear his throat voluntarily; coughing should be encouraged (not checked by opiates) and, if respiration is feeble, hyperventilation of the lungs by carbon dioxide-oxygen inhalation is indicated to prevent atelectasis.

*Bronchoscopic aspiration*—When during or shortly after an operation in the nose, throat or mouth the patient shows signs of pulmonary involvement (cough, cyanosis, possibly early fever) and later the roentgenogram shows atelectasis of a part of the lung, a bronchial embolus should be suspected. Then an immediate bronchoscopy is indicated. If the bronchoscopy reveals a plug in one of the main divisions of the bronchus, this plug can be removed by suction and the symptoms usually subside almost immediately. Unfortunately, as

a rule the bronchial plug lodges in one of the smaller inaccessible bronchioles out of reach of the bronchoscope.

#### TREATMENT

Lung abscess is one of the few kinds of abscess in which "nature" should be given every possible chance for evacuating the pus before surgery is resorted to. To draw correct indications for details of treatment, one must differentiate between the following three kinds of pulmonary abscess: (a) acute lung abscess, (b) chronic lung abscess and (c) multiple lung abscesses.

*Acute Lung Abscess*—This is to be treated along symptomatic lines, for the great majority of acute lung abscesses heal without the necessity of surgical procedure, and surgery in the presence of an acute lung abscess has a prohibitively high mortality rate. The following indications are present:

1 *Rest* Absolute rest must be employed not only during the febrile stage but also as long as there is x-ray evidence of the presence of an abscess. The patient's position should, however, be changed from side to side. This rest treatment should be accompanied by the diet and hygiene usually employed in fever (q. v.).

Paralytic (intestinal) ileus (q. v.) is apt to be a concomitant of almost any type of chest infection, hence the abdomen must be carefully observed.

If the patient is cyanotic he should be placed in an oxygen tent or receive oxygen through a nasal tube introduced into the pharynx. As, however, the shallow breathing resulting from the increased oxygen tension might interfere with a beneficial cough, it may be wise to remove the tent for short intervals.

If the patient is restless, morphine should be given in guarded doses, but the cough reflex should never be greatly impeded with sedatives.

2 *Resistance* One should aim to increase resistance. Transfusion of whole blood is undoubtedly the best "tonic" at the physician's disposal for the septic patient.

Neosarsphenamine should be given whenever spirochetes and fusiform bacilli are found in the sputum. It should be administered at the earliest possible moment and in rather small "tonic" doses (0.15 Gm intravenously) every other day, the effects being carefully observed. Heroic doses may harm the patient. In the late stages, little benefit is to be expected from this treatment. It is not a specific agent in this condition.

Hematinic or cardiotonic therapy may be demanded by the condition of the blood or the circulation.

Vaccine and serum therapy has, in general, been absolutely disappointing.

3 *Bronchial drainage* One should favor bronchial drainage. This means that checking the cough by means of morphine, codeine or any other antitussive is to be excepting possibly temporarily in the early stages when pain and insomnia threaten to exhaust the patient.

Postural drainage, i. e., assuming that position which results in maximum expectoration should be resorted to whenever the opening into the bronchus is large enough to secure good evacuation, and it should be continued for as long a period (from five to twenty minutes) and undertaken as often (five or six times a day) as the patient's strength and inclination permit.

Considerable experimentation may be required to determine the best position, but efforts to discover it are decidedly worth while. In abscesses of the upper lobe it may be the semireclining posture. In abscesses

of the lower lobe it may be secured by a complete head-down position, with the patient's hips and legs across the bed. Occasionally lying on the back over an inverted chair is effective. Postural drainage not only facilitates healing but may do away with the harassing cough during the day as well as the night.

In abscess of the lower right lobe, for example, the best postural drainage is usually obtained by lowering the patient's head until he is almost upside down. To get the patient in this position, one should have him lie across the bed and place a pus basin on the floor at the side of the bed and then have him swing over the bed until his elbows are resting on the floor on each side of the pus basin, with only his hips and legs remaining on the bed. In this position he will often expectorate huge quantities and thus drain himself thoroughly. Naturally, very sick or elderly patients with cardiac or arteriosclerotic changes may not be able to tolerate this position, and a compromise between the best possible position for drainage and that tolerated by the patient must be sought.

There are patients who find it easier to get up material from the bronchi when they are sitting up in

#### PRESCRIPTION 1—*Aromatic Inhalation Fluid*

R	Oil of eucalyptus	8 00 cc
	Oil of pine needles	8 00 cc
	Oil of betula	8 00 cc
	Tr of benzoin	to make 100 00 cc

M Label Add from 1 to 2 cc to hot water in a tea kettle to the spout of which a rubber tube has been attached the patient taking the free end of the tube in his mouth to inhale the steam

#### PRESCRIPTION 2—*Creosote Carbonate Emulsion*

R	Creosote carbonate	7 50 cc
	Tragacanth in fine powder	0 75 Gm
	Syrup	25 00 cc
	Alcohol	6 25 cc
	Compound spirit of orange	6 25 cc
	Distilled water a sufficient quantity	to make 100 00 cc

Mix ingredients in the order named and make an emulsion

Label From one to two teaspoonfuls in milk three times a day after meals

Each teaspoonful (5 cc) contains 0.375 cc of creosote carbonate

bed than when they are lying down. This is because pulmonary ventilation is facilitated by the upright position. In such patients it would be this position that should be resorted to for postural drainage.

Definitely contraindicated is drainage in the inverted posture in very sick patients, especially if they are cyanotic or have high fever, rapid pulse and a low vital capacity. In such patients the inverted posture may actually result in death.

It should be understood, of course, that postural drainage is of no value until the abscess has broken into a bronchus and that, indeed, it is of much greater importance in bronchiectasis than in lung abscess.

Bronchoscopy is chiefly of diagnostic value, but it may also permit removal of granulation tissue or otherwise increase the size of the opening so that the abscess drains more freely through the bronchial tubes. When this can possibly be accomplished, it is much to be preferred to surgical drainage through the chest wall. Hence bronchoscopy should always be employed before surgical opening of the abscess is done, but used otherwise, as an attempt to cure the disease, it is unsurgical. It cannot be carried out often enough to keep the abscess drained, and it may cause a spread of the inflammation. To be of value in the treatment of any abscess, drainage must be continuous or as nearly continuous as possible and a weekly or semiweekly emptying of any pus cavity is of little value.

4 Fetor of sputum. One should antagonize fetor of sputum by means of (a) Vapor inhalation. The Compound Creosote Inhalant (Recipe Book), consisting of equal parts of chloroform, alcohol and creosote may be inhaled from a chloroform mask and in as great a concentration and as continuously as the patient will tolerate. If this proves irritative, (b) steam inhalation, possibly flavored with an aromatic inhalation fluid (prescription 1) may be resorted to, provided it does not cause a feeling of "stuffiness" in the chest. (c) Taking creosote carbonate in ascending drop dosage, from 5 to 15 or more drops shaken up with hot milk, three times daily after meals, or preferably in the form of an emulsion of Creosote Carbonate (prescription 2 from the new edition of Recipe Book), may possibly be of service in lessening fetor, but it must not be employed to the extent of interfering with appetite and digestion or of damaging the kidney. (d) A mouth wash that is strongly flavored, e g, the "N F Dentifrice" (to be prescribed by this title), used immediately each time after the patient has expectorated his foul-smelling sputum, is usually very desirable. One puts into warm water a few drops of this dentifrice, enough to produce a slight turbidity, and thus secures maximum efficiency in the form of an aromatic mouth wash at minimum expense.

5 Roentgen irradiations. These may prove a useful adjunct by clearing up surrounding pneumonic consolidation and favoring liquefaction and early rupture of the abscess into the bronchus.

6 Collapsotherapy. This must be employed with discrimination. It may give rest to the inflamed part. It reduces the size of the cavity that requires obliteration, provided there is no dense abscess wall and there are no adhesions. The collapse may be induced by partial pneumothorax or, if the abscess is in the lower lobe, by phrenicectomy. The selection of cases for this type of therapy requires great care and should be made by one of large experience. The danger of empyema is increased by the use of artificial pneumothorax.

*Chronic Lung Abscess*—1 Surgical drainage. The presence of a more or less dense abscess wall that prevents the success of collapsotherapy indicates surgical drainage. Without it such patients are liable to develop anemia and cachexia, amyloidosis and clubbed fingers, osteoarthropathy and metastatic (e g, cerebral) abscesses. Impairment of proper aeration of blood—cyanosis—is the rule, and there is constant danger of fatal hemorrhage or of a perforation of the abscess with production of pyopneumothorax or mediastinitis. One must therefore not wait too long. When the patient's general condition is obviously deteriorating in spite of all efforts to improve it, one of the following operative procedures is indicated: (a) the one-stage operation, (b) the two-stage operation, (c) bronchoscopic drainage. Accurate localization by means of preliminary x-ray studies is essential before one can decide on the mode of approach. The one great difference between an abscess of the lung and an abscess elsewhere is that the approach to the lung abscess lies through an easily infected potential space, the pleural cavity. If the pleural cavity is obliterated and the lung fixed at the site of the abscess to the chest wall, as it often is, the drainage of such an abscess becomes as simple as the draining of any other subcutaneous collection of pus. If an attempt, however, is made to drain a lung abscess through a nonobliterated or free pleural

space, not only will the lung retract from the chest wall but the now huge pleural cavity will become infected, resulting in a massive empyema.

It is axiomatic that no lung abscess may ever be drained externally until after the pleural space at the site of drainage has been obliterated.

(a) Immediate drainage. It frequently happens in lung abscess situated in the periphery of the lung that the pleural layers will become adherent one to the other as a direct result of the underlying infection. Thus when it becomes time to drain the abscess, the pleural cavity being already obliterated, the drainage can be carried out through simple incision as if the abscess were in the chest wall.

After exposure by resection of a portion of a rib, the abscess is then opened by means of slow coagulation with the diathermy knife or cautery. One must of course, beware of using an explosive general anesthetic, such as ether or ethylene, during such an operation. On the other hand, the plunging of a forceps or of the finger into the cavity is dangerous. It may then be necessary to pack the cavity for the first twenty-four or forty-eight hours because of the occasional free hemorrhage. If electrocoagulation can be used, this may be prevented. The drainage channel is best maintained by a large red rubber tube. Red rubber tubes are x-ray opaque, which is often a decided advantage. Drainage must be continued until the abscess cavity has become obliterated.

(b) Two-stage operation. If adhesions have not been naturally formed, because the inflammatory process is in the depths of the lung far from the visceral pleura or because of the presence of an exudate, or for any other reason, it becomes absolutely essential as the first step in external drainage to obliterate the pleural space at the site of proposed drainage by artificially producing adhesions.

As soon as a "window" has been made into the chest by means of rib resection and before the pleura is incised, one should carefully look for respiratory movements of the lung. If these are present, a nick is made into the pleura, and, at once, gauze is packed into the opening and against the lung. After a week or ten days the packing is removed and the abscess entered as in the immediate drainage operation.

(c) Bronchoscopic drainage. Abscesses near bronchi may occasionally be reached through the bronchoscope.

From what has been said it is obvious that a chest must never be "needled" to make a diagnosis of lung abscess, as such a procedure will probably result in a complicating empyema.

2 Supportive measures. Adequate diet, plenty of bed rest, securing peace of mind and—if possible—a dry, equable climate are important adjuvants to favor the healing of the abscess even after surgical drainage.

*Multiple Lung Abscesses*.—In multiple embolic abscesses in different parts of the lung, surgical therapy is impossible. It is only when multiple abscesses are confined to one lobe and they have become chronic that cautery lobectomy is indicated. After a large part of the chest wall overlying the lobe has been taken away and firm pleural adhesions have been established one advances the cautery, eating out in successive operations more and more of the lung until all the abscesses have either been opened or eradicated. Thoracoplasty may finally expedite the healing. Occasionally, instead of cautery lobectomy, a one-stage lobectomy may be indicated.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT  
HOWARD A. CARTER, Secretary

### KAISERAIRE FILTER VENTILATOR NOT ACCEPTABLE

Manufacturer: H. S. Kaiser Company, Chicago

This ventilator is marketed under the claims that it removes the pollen that causes hay fever and retards and prevents various diseases by preventing germs from entering the rooms and offices in which people live and work.

The filter mat, which is removable, consists of several layers of small paper tubes of decreasing diameter arranged in staggered "herring-bone" fashion, i. e., the first layer of parallel tubes is offset to the right, the next layer, which is smaller in diameter is offset to the left, the next to the right, and so on through the entire mat. This arrangement is suggested so that the air laden with dust and pollen, in order to pass through the entire filter, would have to travel in a zigzag manner. Small particles of matter, having inertia and believed to move in straight lines, would presumably adhere to the wall at the point of impingement. The filter mat is very heavily coated with a thick, very pungent oil, to which the dust and pollen particles are expected to adhere. Air is forced through the filter by means of two fans of the ordinary blade type.

In a laboratory acceptable to the Council, this unit was examined. It was installed in an ordinary bedroom window with the usual precautions taken as to sealing of cracks between unit and window and window-casing. Slides coated with a thin layer of petrolatum were exposed in various parts of the room which was closed for three twenty-four hour periods before the testing of the unit was begun for its pollen removing efficiency. During the last period the unit was operated continuously for twenty-four hours and at that time several slides were exposed at the outlet ducts of the unit. In the course of these three periods, no pollen grain was found on the slides exposed. However, there were numerous dust particles found on the slides which were exposed both in the room and at the outlet ducts of the unit.

At the intake of the filter, while it was in operation, 0.25 Gm of pollen of the giant ragweed (*Ambrosia trifida*) was suspended in the air. The pollen was released within a distance of five feet of the intake. Slides were exchanged in front of the outlet ducts at five minute intervals for a period of one hour, at the end of which time the slide was left for twenty-four hours. Then, at the end of the twenty-four hour period, a fresh supply of slides was placed before the outlet ducts again and allowed to remain for another twenty-four hours. The slides removed within five minutes showed the greatest number of pollen granules, twenty-one per unit area of 18 sq. cm. counted. As the time increased, i. e., toward the end of the hour slides exposed for five minutes showed an average of only three pollen grains per unit area counted. The slide for the first twenty-four hour period, which was placed before the outlet duct at the end of the one hour run, showed only seven pollen grains per unit area. The second twenty-four hour slide showed three pollen grains per unit area counted but, as the outside air by this time probably was almost free from the suspended pollen, doubtless these grains were blown off of the points where they had adhered initially.

Slides exposed in rooms in which dust was settling showed a total of eleven pollen grains per unit area counted for the first twenty-four hours, which represents eleven grains per cubic yard of air, and two grains per cubic yard of air for the second twenty-four hour period.

The pollen counts obtained are high when compared to the counts obtained on other types of filters, such as those of felt or cellulose. The pollen counts indicate a percentage of efficiency for this filter which may afford the very mildly sensitive hay fever subject some freedom from symptoms, but they indicate inadequateness of the filter for the severe type of case in which symptoms are manifested with pollen counts as low as two and three granules per cubic yard of air. The filter would be ineffective, also, in localities where very highly

antigenic pollens are found. As the filter admits dust particles up to 20 microns in diameter, it will admit pollen that is usually much smaller.

One objection to the unit is the highly pungent odor that is given off by the oil. This is most irritating and, in the opinion of the Council, would be a decided drawback to most persons with asthma and to many hay fever sufferers. Pungent, penetrating odors frequently aggravate such sensitive individuals, and a massive dose, such as one is subjected to with this unit, may be harmful to many patients.

In the opinion of the Council, the Kaiseraire Filter Ventilator does not possess adequate efficiency for removing pollen from the air, the volume of air it displaces is insufficient for comfort, and the presence of a pungent, penetrating odor is considered objectionable and possibly harmful to sensitive individuals. Therefore the Council on Physical Therapy voted not to include the Kaiseraire Filter Ventilator in its list of accepted devices.

## Council on Pharmacy and Chemistry

### REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENT  
PAUL NICHOLAS LEECH Secretary

#### THE STATUS OF CERTAIN QUESTIONS CONCERNING VITAMINS

As a result of the increasing importance of questions concerned with vitamin containing foods and medicinal preparations, the Council on Pharmacy and Chemistry and the Committee on Foods of the American Medical Association appointed a joint cooperative committee for study of this field with instructions to report to the two parent groups. The Cooperative Committee consisted of Prof. W. E. Anderson, Dr. E. M. Bailey, Dr. K. D. Blackfan, Dr. S. W. Clausen, Dr. Morris Fishbein, Mr. Raymond Hertwig (resigned Dec. 31, 1935), Dr. P. C. Jeans, Dr. P. N. Leech, Dr. E. M. Nelson, Dr. W. W. Palmer, Dr. G. F. Powers, Dr. L. J. Roberts, Dr. M. S. Rose and Dr. Torald Sollmann.

At a meeting in Chicago October 18-19 the Cooperative Committee arrived at conclusions which have been considered by the Council and the Committee on Foods. The following is a summary of the Council's decisions based on the Cooperative Committee's recommendations which has been authorized by the Council for publication for the information of physicians, manufacturers and the public. Certain other recommendations of the Cooperative Committee will be published by the Committee on Foods.

**Lay Advertising of High Potency Vitamin Preparations.**—In the deliberations of both the Cooperative Committee and the Council it was brought out that considerations of the varying potency of oils, concentrates and crystallized preparations together with those of proved clinical effectiveness and recommended dosage combine to make impossible a categorical ruling on this subject. The Council decided that it would consider vitamin products for advertising both to the public and to the profession on the basis of the general principle that advertising to the public of vitamin preparations for prevention of disease [but not for the treatment of disease] shall be permitted provided the dosages are within the established concentrations which are considered safe, also that the Council shall not accept for sale to the public concentrates or pure forms of vitamins when the facts as to dosage are not available or when the daily dosage recommended is beyond that considered safe. Furthermore that usefulness and necessity as a prophylactic must be established.

The Council in its annual meeting later, adopted the following specific rulings based on the foregoing decisions:

1 Cod liver oil and preparations made by the addition of therapeutically indifferent substances to the untreated oil such as emulsions and malt preparations may be advertised to the public if the prescribed daily dose provides at least 6,250 units

of vitamin A and 625 units of vitamin D. Those are the numbers of units provided by two teaspoonfuls of cod liver oil complying with the N. N. R. standard.

2 Preparations of vitamins A and D other than those included under 1 may be advertised to the public if the prescribed daily dose provides not more than 10,000 units of vitamin A and not more than 1,000 units of vitamin D.

3 Preparations of vitamin A which do not contain a therapeutically significant quantity of vitamin D and for which no recommendations for vitamin D are made may be advertised to the public if the prescribed daily dose provides not more than 10,000 units of vitamin A.

4 Preparations of vitamin D which do not contain therapeutically significant quantities of vitamin A and make no representations for vitamin A may be advertised to the public if the prescribed daily dose provides not more than 1,000 units of vitamin D.

**Dosage of Cod Liver Oil.**—The vitamin A potency (as well as the vitamin D potency) of the official cod liver oil is now higher than that of the cod liver oil on which was based the dosage heretofore recommended in N. N. R. (namely, for infants 3 teaspoonfuls and for adults 6 teaspoonfuls daily). In addition, the lower limit of vitamin A potency per gram of the cod liver oils accepted for N. N. R. is higher than that of the official oil. In view of this the Cooperative Committee considered whether or not a corresponding reduction should be made in the recommended dosage on the basis of vitamin content. It was pointed out that the recommended dosage for infants is largely empirical, though it corresponds to the widest general practice. It was further pointed out that the adult need of vitamin D (except in certain instances) is problematic and that there is a lack of data on the basis of which to determine an adult dosage of vitamin A. The Cooperative Committee referred the question back to the Council for categorical decision. The Council, after considering the report of the Cooperative Committee's deliberations, set the dosage of cod liver oil for infants at two teaspoonfuls daily. This is in effect the dosage statement which will appear in N. N. R. 1936.

**Presence of Antioxidants as Preservatives Particularly in Halibut Liver Oil and Other Fish Liver Oil Preparations.**—At its February 1935 meeting the Council took the following action in reference to antioxidants that manufacturers of accepted products be informed that under conditions of ordinary usage there does not appear to be necessity for use of hydroquinone for the proper preservation of cod and halibut liver oils and that, until more convincing evidence in favor of the practice is submitted, it may not be permitted (Abstracts of Minutes of Annual Council Meeting, THE JOURNAL, June 1, 1935).

Representatives of three firms have requested the Council not to place into effect this ruling. It was the contention of the representatives of these firms (1) that hydroquinone aided in preserving vitamin A activity during the interval between the refining of the oil and the filling of it into bottles or capsules, (2) that after the consumer obtained the fish liver oil he may have used it (particularly when in bottles) in such a manner that the air would increase rancidity and reduce vitamin A potency of the oil. The three firms presented briefs the purpose of which was to show that the use of hydroquinone per se was harmless. Among the arguments in favor of the use of hydroquinone was the statement that its use as an antioxidant over a period of years without reports of fatalities constituted a confirmatory mass experiment.

The Cooperative Committee on Vitamins considered this evidence and came to the conclusion that the firms had failed to demonstrate that under ordinary conditions of use the oxidation which halibut liver oil undergoes is serious, that the matter seemed to involve largely a controversy between certain patent-owning interests.

The Committee pointed out that it is as important to know whether or not the product formed by oxidation of hydroquinone, possibly quinhydrone, is injurious, as it is to know whether hydroquinone itself is injurious. The Committee felt that the mass experiment involved in the use of this antioxidant over a period of years without report of its causing agranulocytosis or similar conditions was of some weight as evidence.

in favor of its harmlessness. The Cooperative Committee emphasized, however, that this was not sufficient evidence of the harmlessness of the use of hydroquinone.

It was the consensus of the Committee that the previous action of the Council should stand but that it be not enforced for another six months in order to permit firms opportunity to gather evidence of a worthwhile nature and that in the meantime no claims for stabilization shall be made.

The Council approved the conclusion of the Cooperative Committee and voted to extend the time for the submission of evidence by the firms for a period of six months.

*Use of Carbon Dioxide as a Preservative and as a Means of Increasing Palatability*—The Cooperative Committee considered this question as the result of claims made by a certain firm for its cod liver oil which is impregnated with carbon dioxide. It was felt that there has not been adduced evidence to warrant permitting a statement that carbon dioxide under ordinary conditions of usage remains dissolved in fish liver oil for a sufficient length of time to impart any change in palatability.

The Cooperative Committee recommended that firms be asked whether or not they have been able to obtain any better evidence to warrant the claim that carbon dioxide when used in fish liver oils increases palatability and prolongs stability, and that in the meantime such claims be not recognized until these firms can produce the satisfactory evidence requested.

The Council adopted the recommendation of the Cooperative Committee.

*Prophylactic and Therapeutic Claims Permissible for Vitamins A, B (B<sub>1</sub> and G), C and D*—The Cooperative Committee adopted for further consideration a statement of permissible claims for each of these vitamins which had been formulated by the Council's referee for vitamin preparations. These statements were considered by individual members of the Cooperative Committee and referred back to the Council's referee, who submitted a revision of the statements to the Council. The Council considered them further and adopted the following statements, which are to appear in N N R 1936.

### Vitamin A

The term 'vitamin A' has been applied to any one of several substances or to a mixture of them producing a certain demonstrable specific physiologic effect. It seems to have been definitely established that there are at least five substances which can produce to some degree this characteristic response in the animal body. These are vitamin A itself, alpha, beta and gamma carotene and cryptoxanthin. The last four of these the precursors of vitamin A, are produced in the plant kingdom, and ingestion of these substances by most animals results in varying degree (depending on the species of animal and the precursor fed) in the formation of a compound having the empirical formula  $C_{55}H_{100}O$  and to which no other name than vitamin A has been ascribed. The extent to which the different precursors of vitamin A can be converted to vitamin A by different species of animals has not definitely been established. The exact function of vitamin A has not been established but the pathologic picture which results from varying degrees of deficiency has been the subject of extensive investigation.

The claims recognized under vitamin A shall be recognized under the precursors of vitamin A only under conditions specified for Carotene (New and Nonofficial Remedies 1936).

*Allowable Claims*—1 Evidence for the significance of vitamin A in human nutrition is based on the fact that a characteristic eye disease, usually called xerophthalmia results from a deficiency of this vitamin.

2 It is generally agreed that the first symptom or at least one of the first clinical symptoms of vitamin A deficiency is night blindness or nyctalopia. For this type of night blindness vitamin A is a specific. Cases of nyctalopia exist which do not respond to treatment with vitamin A. These may be due to congenital defects or to other conditions than vitaminosis A.

3 Present indications are that vitamin A is an aid toward the establishing of resistance of the body to infections in general only when there has been an exhaustion of body reserves of the vitamin and the ingestion of vitamin A is inadequate. It certainly has not been shown to be specific in the prevention of colds, influenza and such infections nor has it been demonstrated that ingestion of vitamin A for in excess of that necessary for normal body function and readily obtained from a properly selected diet is an aid in preventing various types of infections.

4 A deficiency of vitamin A results in a retardation of growth when body stores of the vitamin have been depleted but it must be borne in mind that vitamin A is no more important in contributing to normal growth than any one of the other vitamins, the essential elements or amino acids. Statements conveying the impression that vitamin A is more important in promoting growth than other food essentials are therefore considered misleading and objectionable.

5 There is at the present time inadequate evidence to warrant the claim that the ingestion of sufficient vitamin A will prevent the formation of renal calculi in man.

### Vitamin B (Complex)

The term 'vitamin B' should not be used loosely.

Ample evidence indicates that two or more physiologically active substances play a role in relation to numerous phenomena formerly explained in terms of vitamin B alone. At least two substances have received general recognition in this connection; the existence of others has been reported but the evidence submitted has not been accepted as convincing by all investigators in this field. The differences between the various products referred to is now substantiated by chemical evidences. Thus the crystallized antineuritic vitamin of Jansen and Donath and of at least four other investigators, is a nitrogenous compound of defined composition; the so-called vitamin G appears to belong to the flavine group of compounds that have been extensively studied by Kuhn and others. There is no satisfactory evidence that the flavines have any definite relationship to the development or cure of pellagra.

It seems desirable therefore to insist that claims shall refer clearly to one or more of the following:

- (a) Vitamin B<sub>1</sub> and/or
- (b) Vitamin C (B<sub>2</sub>) and/or
- (c) The undifferentiated mixture of these present in many foods which might be referred to as vitamin B complex or undifferentiated vitamin B.
- (d) Reference to Pellagra preventing value shall be limited to products which have actually been tested for such value and shall not be based on so-called vitamin G assays with rats.

It shall be understood that the terms in (c) above refer not only to vitamins B (B<sub>1</sub>) and G (B<sub>2</sub>) but also to other alleged members of the vitamin B complex. If some other alleged member of the complex is being referred to, the statement might be allowed provided the investigator, who has alleged the existence of the new factor, is cited.

*Allowable Claims*—1 Vitamin B<sub>1</sub> may be cited as of value in correcting and preventing anorexia of dietary origin in certain cases.

There are many causes of anorexia, some referable to infections and the reactions thereto, others to organic disorders, and still others related to faulty diet. Where there is no rather obvious cause of anorexia in question other than a possible dietary one, it is permissible to claim that vitamin B<sub>1</sub> may be of therapeutic value when the condition to be treated is due to a deficiency of that vitamin.

2 Vitamin B<sub>1</sub> is of value in securing optimal growth of infants and children.

Citations in the literature support the claim that a sub-optimal supply of vitamin B<sub>1</sub> results in limitation of growth.

3 Vitamin B<sub>1</sub> is of value in correcting and preventing beriberi.

The consensus of the students of beriberi is that this disease is due primarily to an insufficient supply of vitamin B<sub>1</sub>. There are conditions which probably could be designated as latent beriberi; it does not seem wise at this time to attempt the formulation of a definite statement covering such conditions other than that presented in item 5.

4 Because vitamin B<sub>1</sub> is a dietary essential its administration in concentrated form is of value in some conditions where difficulty in utilizing ordinary foods in the usual way is encountered.

The present status of research on the clinical use of vitamin B<sub>1</sub> for specific diseases other than beriberi and for infant feeding is such that definite claims for therapeutic value in relation to such diseases cannot be recognized. Its use may be indicated, however, in such restricted conditions as pernicious vomiting of pregnancy, tube feedings through a jejunal fistula and the like, because the above permitted statement applies to such conditions and gives an intelligent basis for such therapy.

5 Claims for concentrates of vitamin B<sub>1</sub> offered for clinical use should state the potency in terms of the International Unit. The term concentrate or synonym will not be recognized if the product does not exceed a

potency of 25 International units per gram (or per cubic centimeter), or if it is a natural product which may have been subjected to a process of deliydration

6 In connection with medicinal foods acceptable for N N R, the claim that a food is valuable because of its vitamin B<sub>1</sub> content may be made only if it provides in the quantity of food consumed daily at least 200 units of vitamin B<sub>1</sub>.

Any food preparation having less than such an amount cannot be regarded as a noteworthy medicinal source of the vitamin. In the light of present knowledge the daily requirement for vitamin B<sub>1</sub> appears to be not less than 50 units (International) for the infant and 200 units (International) for the adult.

7 There are many experimental indications in the literature indicating other possible functions of vitamin B<sub>1</sub>, e. g., in influence on intestinal motility and neuritis of various types, and also indications of greatly augmented requirements when metabolism is increased as in hyperthyroidism, neuritis of various types, and infections. It seems too early to permit advertising claims for these items.

#### Vitamin C Cevitamic Acid

There is ample experimental and clinical evidence to show that vitamin C in optimum amounts is an essential dietary constituent. Suboptimal amounts result in the development of clinical and pathologic phenomena to which the descriptive term scurvy has been applied.

The chemical nature of the formerly unidentified essential food substance has been discovered. Its empirical formula is  $C_6H_8O_6$ . Vitamin C has been prepared in commercial quantities both from natural sources and through synthesis. The Council on Pharmacy and Chemistry of the American Medical Association has adopted the nonproprietary designation cevitamic acid for the crystalline vitamin C introduced as Ascorbic Acid.

*Allowable Claims*—1 Definite claims for the therapeutic value of vitamin C should be permitted only in relation to scurvy until further clinical or experimental evidence has substantiated its usefulness in other states.

2 Vitamin C is acceptable for the correction and prevention of scurvy. This effect has been established experimentally and by clinical investigation.

3 It may be permissible under certain conditions to refer to the therapeutic value of vitamin C in early and latent scurvy. Convincing clinical evidence has established that this state does occur. It would be well to emphasize the fact that the diagnosis rests, however, on the basis of roentgenologic evidences in the long bones, and possibly failure to excrete an optimum amount of cevitamic acid in the urine.

4 Dental caries, pyorrhea, certain gum infections, anorexia, anemia, undernutrition and infection alone are not in themselves sufficient indications of vitamin C deficiency but according to experimental and clinical investigation they may be concomitant signs of vitamin C deficiency. Therefore, it would be permissible to accept the claim for the therapeutic value of vitamin C in these symptomatic conditions *only when* it is definitely stated that they are the consequences of a deficiency or suboptimal amount of vitamin C or when there is a pathologic interference with assimilation of the amount necessary for the preservation of health.

5 Unless more convincing evidence is present than is now available, no claim referable to the anti-infective effect of vitamin C will be recognized. Secondary infections are characteristic of disturbances of nutrition, particularly in all vitamin deficiency diseases. It has not been established that vitamin C has a therapeutic effect which directly influences associated secondary infections in scurvy.

6 Because vitamin C is a dietary essential its administration in concentrated form is of value in conditions where difficulty in introducing orally or utilizing ordinary foods in the usual way is encountered. Vitamin C (cevitamic acid) is accepted as an essential dietary constituent in infant feeding but it should not be accepted for use in the treatment of diseases except according to the conditions mentioned above. It is generally administered in the form of a vitamin C carrying juice. When there is persistent vomiting, diarrhea or any other condition preventing its utilization in proper amounts it would be permissible to give vitamin C parenterally in concentrated form as sodium cevitamate.

7 Concentrates of vitamin C offered for clinical use must state the potency in terms of the International unit. The

International unit for vitamin C, which was formerly defined as the vitamin C activity of 1 cc of lemon juice, has now been defined as the vitamin C activity of 0.05 mg of 1 cevitamic acid (ascorbic acid). This is the quantity of 1 cevitamic acid usually found in 0.1 cc of lemon juice.

8 The claim that a food is valuable because of its vitamin C content should be permitted only if it provides a daily intake of at least 250 units of vitamin C.

9 A reasonable general statement regarding allowable claims for vitamin C would be as follows:

An optimum amount of vitamin C should be supplied at all ages for its therapeutic value in preventing the development of acute or latent scurvy.

Claims for therapeutic value of vitamin C may be accepted when the agent is described as a corrective measure for scurvy due to a demonstrable absence or a suboptimal quantity in the diet, or in cases in which it is definitely known that there is interference with the absorption of an optimal amount.

Advertising of vitamin C for such symptoms as failure to gain in weight or stoppage of growth, anorexia, anemia, infections, symptoms referable to the central nervous system or hemorrhagic conditions cannot be accepted unless it is definitely stated that the symptoms are referable to a demonstrable deficiency of vitamin C.

The cevitamic acid equivalent or potency in terms of International units should be stated in all dosage claims for vitamin C. Cevitamic acid (vitamin C) is easily decomposed in presence of certain other substances, therefore, care should be exercised against administering it (or orange juice) in mixtures, or by such procedure as to render it ineffective.

#### Vitamin D

The term "vitamin D" is applied to one or more substances which function in the proper utilization of calcium and phosphorus. Vitamin D has been produced in crystalline form as one of the products of ultraviolet irradiation of ergosterol and shown to be a sterol having the empirical formula  $C_{28}H_{44}O$ . Naturally occurring vitamin D has not been isolated, but there is evidence suggesting that it may not be identical with the artificially produced substance, and that more than one natural compound may function as the vitamin.

*Allowable Claims*—1 Vitamin D is recognized as a specific in the treatment of infantile rickets, spasmophilia and osteomalacia, diseases which are manifestations of abnormal calcium and phosphorus metabolism. Vitamin D is valuable in the preventive as well as curative treatment of these diseases. Complications such as certain renal diseases or glandular malfunction may preclude normal response to vitamin D therapy. During acute infections, especially of the gastro-intestinal tract, vitamin D may prove ineffective because poorly absorbed.

2 Direct exposure of the skin to ultraviolet light from the sun or from artificial sources results in the formation of vitamin D within the organism but the Council cannot recognize statements or implications that vitamin D has all beneficial effects of exposure to sunshine.

3 There is clinical evidence to justify the statement that vitamin D plays an important role in tooth formation and maintenance of normal tooth structure, but there is no warrant for the claim that adequate vitamin D intake will insure normal tooth structure or that adequate vitamin D intake will prevent dental caries.

4 Animal experimentation has shown that correction of an inadequate intake of vitamin D results in the more economical utilization of calcium and phosphorus and also that the undesirable effects of improper ratios of calcium and phosphorus in the diet can largely be overcome by normal intake of vitamin D. The importance of these observations in their application to man is not entirely apparent because of the lack of adequate clinical evidence showing the availability of different forms of calcium and phosphorus, but it may be stated that vitamin D has a favorable influence on calcium and phosphorus metabolism.

5 The vitamin D requirement is greatest during the period of infancy. Beyond the age of infancy the exact vitamin D requirement of man under any specified conditions is not known but it appears that the requirement during pregnancy and lactation is increased.

*Status of Vitamin E*—The Cooperative Committee recommended that the Council declare that there is no evidence to indicate that vitamin E has therapeutic merit and that the Council do not accept any vitamin E preparations.

**Molt Preparations with Cod Liver Oil and I ntersterol Claimed to Contain Vitamins B<sub>1</sub> and G**—The Council maintains that if a preparation contains vitamins B<sub>1</sub> and G as well as A and D, in therapeutic amounts, it cannot be considered acceptable, since no evidence has been adduced to show that combinations of vitamins A, B<sub>1</sub>, D and G are rational therapeutically or pharmacologically. On the other hand if the vitamins B<sub>1</sub> and G are natural contaminants in the vehicle, it is held that they are present in such small amounts as not to be therapeutically significant and claims for them may not be recognized.

The Cooperative Committee took the position that in the case of certain accepted preparations containing vitamins A, B (complex) and D the Council should not recognize claims for the vitamins B and G content in view of the insignificant amounts present. The Council endorsed the opinion of the Cooperative Committee and manufacturers of accepted products of this category have been informed that no claims for the vitamin B and G content of such preparations will be recognized and that after Jan. 1, 1937, not even the statement that these vitamins are present should be made, because of the danger of arousing false implications.

**High Potency Viosterol Preparations**—Inquiries have been received from various sources concerning the marketing of high potency viosterol preparations, particularly for use in the treatment of rheumatism. The Cooperative Committee felt that experimentation with products in cases of arthritis is susceptible to so many misinterpretations that those making inquiry should be advised to use great caution in such experiments, and that the use of very high potency preparations by general practitioners at this time is not to be commended.

Inquiries have been received from a manufacturer of pharmaceuticals and Dr. C. I. Reed whether or not the Council would suggest to the Wisconsin Alumni Research Foundation that it encourage the sale of high potency viosterol preparations to the physician by granting their licensees the privilege to market such high potency preparations.

The Council concurred in the Cooperative Committee's recommendation that the manufacturer and Dr. Reed be advised (1) that the Council is never opposed to experimental investigations under proper directions and facilities, but that the Council does not feel that there is at this time sufficient evidence to warrant the acceptance of viosterol preparations of very high potency, and (2) that it declines to suggest to the Wisconsin Alumni Research Foundation that the marketing of such high potency preparations to the medical profession by its licensees is advisable.

## NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

## TETANUS TOXOID, ALUM PRECIPITATED

**Tetanus Anatoxin**—A preparation of tetanus toxin after the formaldehyde detoxifying procedure of Ramon whereby the toxic action is greatly diminished with no loss of antigenic potency. Alum precipitation furthers this action by freeing the antigenic substance from the reaction-producing proteins of the culture medium.

**Actions, Uses and Dosage**—Tetanus toxoid is recommended for the production of active immunity to tetanus. One cc is injected subcutaneously, preferably in the region of the deltoid. Approximately three months later the second and final injection of 1 cc is given. The immunity thus produced is reasonably persistent. However, it has been shown that if some time after the original immunization a single injection of 1 cc of toxoid is given there results a prompt (within two weeks) and marked rise in the antitoxic titer of the serum. Thus in cases of injury to persons previously immunized an injection of tetanus toxoid may suffice to protect against tetanus in place of the usual tetanus antitoxin. It should be borne in mind that in these cases several weeks is required following the second injection of toxoid before immunity may be assumed to be well established. Therefore in any dubious instance the conservative course is the administration of antitoxin. Active

immunization to tetanus would appear to be a desirable procedure in the case of individuals whose work subjects them to a greater than normal hazard of the disease.

The National Drug Co. Philadelphia

**Refined Tetanus Toxoid (Alum Precipitated)**—Marketed in packages of two 1 cc vials (one immunization treatment) and in packages of one 10 cc vial (five immunization treatments).

## Committee on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BING, Secretary

### CELLU BRAND CARROTS, WATER PACKED

**Distributor**—Chicago Dietetic Supply House Inc., Chicago

**Packer**—Eugene Fruit Growers Association, Eugene, Ore.

**Description**—Canned carrots, packed in water.

**Manufacture**—Selected carrots are topped, washed, preheated to loosen the skin, mechanically peeled, inspected, trimmed, graded and hand packed in cans. Small carrots are packed whole, large sizes are diced, quartered or sliced. The cans are filled with water, heated, sealed and processed.

Analysis (submitted by distributor) —	per cent
Moisture	90.3
Total solids	9.7
Ash	0.8
Fat (ether extract)	0.3
Protein (N X 6.25)	1.0
Crude fiber	1.0
Starch (diastase method)	5.3
Carbohydrates other than crude fiber (by difference)	6.6

**Calories**—0.3 per gram, 9 per ounce.

**Claims of Manufacturer**—Choice quality carrots packed with out added sugar or salt. For use in special diets in which sugar or salt is proscribed or in quantitative diets of calculated composition.

### STEPHENS BRAND GRAPEFRUIT JUICE

**Manufacturer**—Natural Food Products Company, Orange, Calif.

**Description**—Canned Arizona and California grapefruit juice, retaining in high degree the natural vitamin C content.

**Manufacture**—Arizona and California tree ripened grapefruit is thoroughly washed, inspected, automatically cut and reamed. The juice is strained, deaerated, treated with ultraviolet rays for inactivation of enzymes, vacuum sealed and heat processed.

Analysis (submitted by manufacturer) —	per cent
Moisture	88.3
Total solids	11.7
Ash	0.4
Fat (ether extract)	0.2
Protein (N X 6.25)	0.7
Reducing sugars as invert sugar	5.8
Nonreducing sugars as sucrose	2.2
Crude fiber	0.1
Carbohydrates other than crude fiber (by difference)	8.9
Titratable acidity as citric acid	1.4

**Calories**—0.5 per gram, 14 per ounce.

**Assay**—Chemical determination (iodine titration) of ascorbic (ascorbic) acid shows 0.5 mg. per cubic centimeter.

**Claims of Manufacturer**—Practically equivalent to fresh juice in vitamin C. For all table and dietary uses of fresh juice.

### MILL BROOK BRAND EVAPORATED MILK

**Distributor**—Winner Market, Lock Haven, Pa.

**Packer**—The Page Milk Company, Merrill, Wis.

**Description**—Unsweetened evaporated milk. The same as Page Brand Evaporated Milk (THE JOURNAL, May 30, 1931, p. 1872).

## THE ARMY MEDICAL LIBRARY

William H. Welch once asserted that the Army Medical Library and its *Index Catalogue* are America's greatest gift to medicine. Sir William Osler was so grateful for its services that he gave to the library the manuscript of his farewell address delivered at Johns Hopkins University. From a small collection of books placed in the office of Surgeon General Lovell a hundred years ago the Army Medical Library has grown to be today the largest medical library in the world.<sup>1</sup>

The century of growth cannot be reviewed without reference to an incident in the life of John Shaw Billings, an army surgeon. When writing his graduating thesis at Miami Medical College, Billings had difficulty in finding statistics on the results of certain surgical operations. For six months he ransacked the libraries in Cincinnati, Philadelphia, New York and elsewhere. He became convinced that there was not a medical library in the country in which a student would find a large part of the literature relating to any medical subject. This experience led him, when the opportunity came years later to establish for American physicians a medical library and an index that would spare them the drudgery of consulting thousands of texts to find a dozen useful references. Billings began his great work of collecting and cataloguing medical literature in 1868, with a few thousand dollars left over from the Civil War hospital funds turned over to him by the surgeon general. He envisioned the greatest undertaking in bibliography that had ever been done in any scientific field. In 1876 he published a specimen catalogue of the library and submitted it to the medical profession for criticism. In style and arrangement this "Specimen Fasciculus" was practically the same as that of the *Index Catalogue* of today. Billings continued the preparation of the *Index Catalogue*, and at length Congress appropriated funds for the printing. Three complete series of the *Index Catalogue*, comprising many volumes, have been published. Volume one of

the fourth series has gone to press and will appear during 1936, to mark the hundredth birthday of the Army Medical Library. These volumes catalogue and index all the meritorious medical books, theses and articles that have been published throughout the world. In 1895, when the first series of the *Index Catalogue* was completed, Billings left the army and devoted himself to consolidating and cataloguing the public libraries in New York City and later to the organization of the Carnegie Institution in Washington.

Billings established in 1879 another monumental work, the *Index Medicus*, which provided monthly a classified record of the current medical literature of the world. Its classification was more general and less subdivided than that of the *Index Catalogue*. The *Index Medicus* was never a government publication. The subscribers were limited chiefly to medical libraries, and there were financial difficulties from the start. About 1899, when the founders could no longer continue publishing the *Index Medicus*, Osler made a plea before a meeting of the American Medical Association for physicians to subscribe in order to keep it alive. In 1903 the Carnegie Institution at Washington took over the *Index Medicus* and continued to sponsor its publication until 1927, when it was merged with the *Quarterly Cumulative Index*, which had been published by the American Medical Association since 1916. The combined index has since been known as the *Quarterly Cumulative Index Medicus*.

The amount of space occupied by the Army Medical Library in Washington during the early years was so small that the boxes of books had to be opened in the yard. Congress then appropriated \$200,000 for a building, and in 1887 the present three story building occupied by the library and museum at Seventh and B streets S.W. was opened to the public. That building has been occupied for fifty years and has long since been outgrown. The overflow of books now crowds the basement and every nook. The need for a larger building was so obvious as long ago as 1919 that Congress purchased a new site for the library at the Army Medical Center on the outskirts of Washington.

The Army Medical Library has now more than 941,181 volumes. It has about 19 per cent as many volumes as the great Library of Congress, and yet it receives about 98 per cent as large an annual appropriation for purchases. It has some of the rarest books in the world. Of about 600 medical incunabula known, it has 450. The Army Medical Library has the only known copy of some medical works. It contains a more complete file of French theses than the Library of the Medical Faculty of Paris.

In addressing the International Medical Congress in London in 1881, Billings said "If the entire medical literature of the world, with the exception of that which is collected in the United States, were now to be destroyed, nearly all of it that is valuable could be reproduced without difficulty."

## "FULL STEAM" OR CAUTION IN SOCIAL SECURITY

When the Committee on the Costs of Medical Care brought in its final report, *THE JOURNAL*<sup>1</sup> pointed out that the choice seemed to lie with the medical profession and the public as to whether or not changes in the nature of medical practice were to come by evolution or by revolution. In the years that have elapsed, the public seems wisely to have chosen to proceed cautiously and carefully rather than to order "full steam ahead." Nevertheless, proponents of socialized medicine continue to urge and to make propaganda for the revolution that the medical profession and the public want to avoid. Conspicuous among those who demand haste are Michael Davis, representing the Rosenwald Foundation, Nathan Sinai, who has at various times represented various groups, and Dr. Hugh Cabot, who seems mostly to represent himself.

In a recent discussion on the subject of social security, held in the Graduate School of Business Administration of Harvard University these three proponents of speed again stated their points of view. Dr. Cabot did not hesitate to say that the medical profession does not seem to be able to fit itself into an economic age and that it should long since have realized that it must become a business and cease to be a profession. Mr. Sinai deplored the manner in which his plans for Michigan had been opposed and indicated his impression that the medical profession in this country is an obstructionist body. Mr. Davis, who has on previous occasions stated his belief that medicine proceeds on a bicycle while civilization proceeds in an airplane, again bemoaned the delay of the American medical profession in adopting some of the plans which he and his associates of the Rosenwald Foundation have been so busily pushing during the last four years. In the course of their discussions, these proponents of socialized medicine condemned the principles adopted by the House of Delegates of the American Medical Association at the Cleveland and subsequent sessions as being planned to delay rather than to hasten progress. Any one familiar with the changes that have occurred, with the experiments that are now under way, and with the statements made by representatives of organized medicine during the past three years, will know that the allegations of these three propagandists are not warranted. The studies made by the Bureau of Medical Economics of the American Medical Association indicate that already many an ill founded and unwarranted experiment in changing the nature of medical practice has failed and disappeared. As yet there is no scientific evidence to indicate that any one of the plans now in effect represents the ideal.

The substantial progress of medicine has been brought about by a system of trial of test and experiment which is itself responsible for the substantial character of the progress. There is no more reason

why medicine should discard its scientific methods in performing social experiments than there is reason for discarding scientific methods and embarking on wishful thinking in the laboratory and faith-healing in the hospital. Reckless experimenters in the so-called social sciences may shout "full steam ahead!" The organization and structure of scientific medicine is more likely to be salvaged from the wreckage into which many of the other social and economic organizations are plunging by observing the caution which medical leaders know is imperative for a safe advance.

## CITRIC ACID IN METABOLISM

Among the more striking recent advances in nutrition are those concerned with the physiologic significance of the less well known constituents of plant and animal tissues. These substances are likely to be overlooked entirely when a dietary component is evaluated for nutritional purposes on the basis of the conventional food analysis alone. Thus the various carotenes and lycopanthine, which appear as natural pigments in plants, are now known to be precursors of vitamin A, the traces of copper, manganese and zinc occurring in plant and animal tissues and previously receiving little if any attention have been demonstrated to be indispensable for nutritive well being in the body, the small amounts of the nitrogenous base choline, which is rather widespread in food substances but which heretofore has been looked on as a pharmacologic agent with limited application is now known to exert a profound influence in certain phases of the metabolism of fat in the mammalian organism. In this category of less well known constituents of natural food substances, are certain known and doubtless other as yet unrecognized, organic acids and their salts. Malic, tartaric, oxalic, citric, benzoic and quinic acids have long been known to occur in plant saps and acid fruits and berries, the salts of some of these acids have received considerable attention because in the course of metabolism they are transformed to bicarbonate and thus promote alkalization of the body fluids. Renewed attention has recently been directed to citric acid, however, and some unsuspected facts have been discovered with respect to its metabolism.

Citric acid is a constituent of animal tissues and body fluids. It was isolated from milk in 1888 and the quantity has subsequently been found to be from 1 to 4 Gm per liter. It occurs constantly in human urine and has been found in the urine of many species of the lower animals. It is a constituent of blood, the ratio of distribution between plasma and cells in the dog being approximately 16<sup>1</sup>. Citric acid has been found in the aqueous humor, saliva, cerebrospinal fluid, the secretion of the male sex organs, and amniotic fluid. The output in urine is invariably increased by administration of alkali or of salts of organic acids that

<sup>1</sup> The Committee on the Costs of Medical Care editorial *J. A. M. A.* 99: 1950 (Dec. 1) 1932

<sup>1</sup> Pucher C. W., Sherman C. C. and Vickery H. B. *J. Biol. Chem.* 115: 235 (Feb.) 1936

increase the  $p_H$  of the urine. After meals the concentration in the urine is augmented, although this is independent of the change in reaction of the urine.<sup>2</sup> That citric acid is synthesized by the organism has been demonstrated by recent studies of Sherman, Mendel and Smith.<sup>3</sup> Three dogs were given a citrate-poor ration along with sodium bicarbonate for periods varying from eighteen to forty-five days. In these animals the excess citric acid excreted over that ingested was 5.2, 10.3 and 7 Gm. respectively over the entire experimental period. It was also observed in the course of this study that the concentration of citric acid in the urine after administration of bicarbonate was elevated to a far greater extent than was that in the blood, a fact suggesting active participation by the kidney in the process.

In further studies<sup>4</sup> the Yale investigators have shown that the body possesses a large capacity to oxidize citric acid. In different experiments in which the animals were maintained on a citrate-poor ration, amounts of from 0.5 to 2 mg. per kilogram of body weight were oxidized to the extent of more than 99 per cent. Under these conditions, i. e., when the free acid was given, there was no effect on the urinary  $p_H$ . Sodium citrate, on the other hand, produced a marked increase in the alkalinity of the urine.

The close parallelism between the excretion of citric acid and the change in reaction of the urine has suggested that it partakes in the biochemical mechanism whereby the acid-base balance of the body is regulated. Possibly it represents the end product of a type of metabolism emphasized only under certain conditions. Thus far the attempts to correlate the formation of citric acid with the metabolism of any one of the major foodstuffs have not been notably successful. The elucidation of the metabolic significance of this compound thus remains an alluring problem.

## Current Comment

### REGISTRATION UNDER HARRISON NARCOTIC ACT

Every physician registered under the Harrison Narcotic Act must reregister on or before July 1 with the collector of internal revenue of each district in which he maintains an office or a place for the treatment of patients. Failure to reregister within the time allowed by law adds a penalty of 25 per cent to the annual narcotic tax payable at the time of registration and in addition makes the physician in default liable to a fine not exceeding \$2,000, or to imprisonment for not exceeding five years, or to both. The Commissioner of Internal Revenue has been so lenient in the past in enforcing the criminal penalties provided by the act

that many physicians seem to have assumed that promptness in reregistration is not material. Year after year they have registered tardily. Since repeated warnings have failed to correct the situation, the commissioner has recently given negligent or recalcitrant physicians the choice between paying substantial sums by way of compromise in lieu of the penalties for their offenses or, as an alternative, accepting criminal prosecution, with resultant publicity and liability to fines of indefinite amounts and possibly imprisonment. This was an act of grace on the part of the commissioner, since he might have instituted criminal prosecutions without allowing the offending physicians any choice in the matter. If the course that the commissioner has adopted does not produce the desired promptness in registration, he will have no recourse other than criminal prosecution to attain that result. If tardiness in registration results in criminal prosecutions, with incidental publicity and the possibility of fine and imprisonment, physicians will recognize that ample notice has been given them.

### DERMATITIS FROM WRIST WATCH STRAPS

The number of substances that have been alleged to produce dermatitis when placed in contact with the skin of sensitive persons is not small. Within the past few months, two substances that may be present in commonly used materials, lip stick and adhesive plaster, have been added to this list.<sup>1</sup> A recent report<sup>2</sup> describes still another possible source of dermatitis-producing agents, namely, wrist watch straps. An investigation of the material was begun because of a number of complaints received by a certain watch manufacturing concern that the straps used on their watches were causing irritation of the skin. The straps on which complaints were made came from one particular lot and other straps of the same lot produced dermatitis varying in severity from an erythema to severe inflammation when tested on volunteers who worked in the factory. The leather used in the manufacture of the straps was traced to its source and the methods of tanning and dyeing were studied. It was learned that all the straps in the offending lot were dyed by a different process from those previously supplied, because of a request from the watch manufacturer for a strap of "fast black color and sweat proof," and that the dyes used contained amyl black and "Oil Yellow T" (amido azotoluene). Patch tests on volunteer factory workers were then made with samples of the strap at each stage of preparation in order to ascertain the identity of the irritating ingredient. The untreated, tanned leather did not cause dermatitis, nor did the leather after treatment with the "thinner" or with the lacquer. However, severe dermatitis was observed in a number of the subjects receiving applications of the dyed leather. Further patch tests demonstrated that the dye amyl black was inert but that the dermatitis was due entirely to the second dye, amido azotoluene. This study clearly shows that the dye amido azotoluene

should not be used in the preparation of leather for such articles as gloves, shoes, hat bands and wrist watch straps, which are worn next the skin. Such undesirable occurrences as the outbreak of dermatitis just described should afford sufficient reason for urging manufacturers to test adequately for possible dermatitis-producing effects such products as are designed to be applied to or worn next the skin before they are released for use by the public.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

### ARKANSAS

**Society News**—At a meeting of the Sixth Council District Medical Society in Prescott, recently the speakers were Drs. Grandison D. Royston on "Importance of Symptoms in Pelvic Disorders", Joseph Hoy Sanford, "Obscure Abdominal Pain—Importance of Urinary Tract Investigation", Joseph W. Larimore, "The Ileocecal Segment," and Ernest Sachs, "Early Diagnosis of Brain Tumors." All are of St. Louis.—In an exchange program, recently, members of the Pulaski County Medical Society, all of Little Rock, addressed the Sebastian County Medical Society. Drs. William V. Newman, on "Sulfur Treatment of Arthritis", Robert A. Milliken "Arthrodesis" and Henry F. ### CONNECTICUT

**Dr. Greenway to Retire at Yale**—Dr. James C. Greenway, who has been director of the department of university health at Yale, New Haven, since it was established in 1916 will retire in June and will be succeeded by Dr. Orville F. Rogers who is now assistant director of the department. Dr. Greenway graduated from Yale in 1900 taking his degree in medicine at Columbia University College of Physicians and Surgeons in 1904. Dr. Rogers has been associated with the university department of health since its organization and has been assistant director since 1921. He graduated from Harvard Medical School, Boston.

**Nearly Four Hundred Cases of Scarlet Fever**—Three hundred and ninety cases of scarlet fever have been reported to the New Britain Board of Health in an outbreak having its onset in the latter part of December. The disease ran an unusually mild form, it was stated, resulting in a large number of parents not calling a physician consequently the patients were mingling with others and spreading the disease. A daily inspection was instituted in the schools and all children found with a rash or desquamating were excluded and referred to the board of health. The board of education closed the schools for two weeks, but this action was not recommended by the department of health, it was stated.

**Study of Laws Relating to Automobile Accidents**—A temporary commission has been appointed in Connecticut to study financial responsibility laws as they relate to automobile accidents, according to the *New England Journal of Medicine*. Members of the commission are Michael A. Connor motor vehicle commissioner, John C. Blackall, insurance commissioner, and Superior Court Judge Frank P. McEvoy. Informal meetings have been held with various groups. At a meeting March 9, representative physicians from the eight counties of the state revealed that hospitals in Connecticut are losing money caring for persons injured in automobile accidents who have no means of paying for their treatment. In many of these cases, it was stated, the responsible person carries no liability insurance and the hospital has no means of collecting its costs.

### FLORIDA

**Personal**—Dr. Shaler A. Richardson, Jacksonville, has been appointed a member of the state board of health, succeeding the late Dr. Harry Dash Johnson, Daytona Beach.—Dr. James Mayey Dell, Gainesville, was recently appointed superintendent of the Florida Farm Colony for the feeble-minded to succeed the late Dr. James H. Miss Marian Telford, national chairman of safety for the congress, who is the consultant on child safety and director of field activities for the National Safety Council, is directing the work.

**Fund for Medical Aid**—A trust fund will be set up under the will of the late Addison H Gibson, Pittsburgh, to procure medical aid for impoverished ill persons and to help deserving young men obtain a college education, according to the New York Times. One half of the estate valued at about \$2,300,000, will be used to procure medical aid or hospital facilities for poor and needy persons although the trustees are also permitted to donate directly to hospitals or other institutions furnishing such aid. The will stipulates that the other half will be used for loans to worthy young men desiring a college education. A low rate of interest is to be charged in these instances the will states although this too depends on the discretion of the trustees.

**Fund for Grants in Medical Sciences**—The National Research Council announces that a limited fund is available for grants in medical sciences. Applications must be submitted to the secretary, division of medical sciences of the council 2101 Constitution Avenue Washington, D C on or before October 1 to be considered at the November meeting. At the April meeting of the committee the following grants were made:

Peter Heinbecker assistant professor of surgery Washington University School of Medicine the mechanism of the altered response of smooth musculature to exogenous epinephrine.

Albert P Krueger associate professor of bacteriology University of California Medical School Berkeley studies on the nature of bacteriophage.

Charles Phillip Miller associate professor of medicine University of Chicago the immunologic properties and toxicity of some chemically isolated fractions from meningococcus.

Carl C Speidel PhD professor of anatomy University of Virginia School of Medicine Charlottesville, observations on nerve and striated muscle fibers subjected to centrifuging at high speeds.

Ernst A Spiegel professor of experimental and applied neurology Temple University School of Medicine the function of the cortical labyrinth centers and their relation to the uncortex.

Since the funds which have been placed at the disposal of the National Research Council during the past few years for the making of research grants have been discontinued there will be no further meetings of the committee on grants in aid.

**Medical Bills in Congress—Changes in Status** H Res 460 has passed the House authorizing the Speaker to appoint a committee of five members to investigate the activities of the departments, bureaus, boards, commissions, independent agencies, and all other agencies of the executive branch of the government with a view to determining whether any such agencies should be coordinated or abolished. The House and Senate have adopted the report of the conferees on H R 11035 the war department appropriation bill, which report authorizes the reestablishment of medical units in the Reserve Officers Training Corps. H R 12527, the navy department appropriation bill, has passed the Senate. A provision in the bill authorizing an appropriation to start construction of a naval medical center in Washington was stricken from the bill by the Senate. H R 12556 has passed the House, proposing to create a Treasury Agency Service. The bill does not propose to transfer to the newly created Treasury Agency Service the functions now exercised by the Bureau of Narcotics as did the bill of which H R 12556 is a redraft but authorizes the Secretary of the Treasury to coordinate the functions conferred on the new service with the functions of investigation, detection or prevention of the violations of the narcotic laws conferred or imposed by law on the Bureau of Narcotics.

**Society News**—At the annual meeting of the American Association of Pathologists and Bacteriologists in Boston, April 9 Dr Nathan C Foot, New York, was made president and Dr Earl B McKinley, Washington D C vice president. The next annual meeting will be in Chicago—Dr Frederic T Lewis, Boston, was elected president of the American Association of Anatomists at the annual convention at Duke University, Durham N C April 11. The 1937 convention will be at the University of Toronto, Canada, April 25-27—The National Conference on Visual Education and Film Exhibition, formerly known as the DeVry Summer School of Visual Education will be held at the Francis W Parker School, Chicago June 22-25—The American Association for the Study of Goiter will hold its annual meeting in Chicago June 8-10, with headquarters at the Drake Hotel, under the presidency of Dr Julius R Yung, Terre Haute Ind. Clinics will be conducted at the morning sessions and papers will be presented by the following physicians: James B Collip, Montreal, Willard Owen Thompson, Chicago, Jacob Lerman, Boston, William T Salter, Boston, John de J Pemberton, Rochester, Minn, Saul Hertz, Boston, James H Means Boston, Frederick A Coller, Ann Arbor, Mich, James H Hutton, Chicago, Nathan A Womack, St Louis, Warren H Cole, St Louis, Henry S Plummer, Rochester, Minn, James A Lehman, Philadelphia, Arthur E Hertzler, Halstead, Kan, Thomas C Davidson, Atlanta, Ga, David Henry Poer, Atlanta, Charles H Arnold, Lincoln, Neb, Frank H Lahey, Boston, Frederick S Wetherell, Syracuse, N Y, Alfred H Noehren, Buffalo, George E Beilby, Albany, N Y, John C McCintock, Arlington Heights Ill, D Roy McCullagh, Ph D, Cleveland, and H J Perkin, Boston.

## CANADA

**Personal**—Dr James S Baxter, assistant professor of anatomy at McGill University Faculty of Medicine since 1934 will leave for England soon where he will join the staff of the University of Cambridge, Science reports.

**Dr Fleming Named Dean at McGill**—Dr Albert Grant Fleming professor of public health and preventive medicine and director of the department, has been appointed dean of McGill University Faculty of Medicine Montreal to succeed Dr Charles F Martin, who retires August 31, having reached the age of 67 years. J C Simpson LL.D secretary of the faculty of medicine and chairman of the committee on physical education will fill the newly established position of associate dean. Dr Fleming who is 48 years of age, graduated from the University of Toronto Faculty of Medicine in 1907. Last year he was appointed secretary to the health insurance committee of the British Columbia College of Physicians and Surgeons.

**Society News**—The Health League of Canada has recently been formed to replace the Canadian Social Hygiene Council and will include other aspects of public health in its program. Dr Gordon A Bates Toronto for many years associated with the original organization is director—Dr Alexander Randall Philadelphia addressed the Toronto Academy of Medicine March 3 on Obstructive Uropathies—Dr Karl M Wilson Rochester N Y addressed the Montreal Medico Chirurgical Society recently on maternal mortality—Dr Walter C Alvarez Rochester Minn addressed the medical profession of Winnipeg February 5 on "Physiology of the Gastro Intestinal

Tract"—The annual meeting of the Canadian Public Health Association will be in Vancouver, June 22-26, in conjunction with the Western Branch of the American Public Health Association and the Canadian Tuberculosis Association

### FOREIGN

**International Orthopedic Meeting**—The congress of the International Society of Orthopedic Surgery will be held in Bologna, Italy, September 21-25. The last day will be spent in Rome, where orthopedic clinics will be arranged at a new clinic.

**Dedication of Eastman Dental Dispensary**—The Eastman Dental Clinic of Stockholm, Sweden, given to the city by the late George Eastman, Rochester, N. Y., was to be dedicated April 25 in the presence of King Gustaf. This is the fourth of five European dental clinics for which Mr. Eastman gave \$1,000,000 each, the first having been opened in London in 1931. The second was opened in Rome in 1933, the third in Brussels in 1935. It is expected that the last, which is to be in Paris, will be completed early in 1937. The cornerstone was laid in July 1935.

**Congress for Experimental Cytology**—The fourth International Congress for Experimental Cytology will be held in Copenhagen, August 10-15. Subjects for the sessions will be experimental morphology, electrophysiology of the cell, experimental cell pathology and biology of irradiation, histochemical problems and cell metabolism and physical chemistry of the cell. Those desiring to present papers and demonstrations should submit the titles together with brief summaries, before June 1. They are further requested to give exact information on the nature of the material to be demonstrated and the size of lantern films and cinema films. Those who plan to attend should notify Dr. Harald J. Okkels, secretary, Institute for Pathological Anatomy, 11 Frederik 51 Vej, Copenhagen, Denmark.

**Plans Approved for Jerusalem Medical Center**—Plans with the Hebrew University in Jerusalem were recently approved by the building committee and it is expected that for the Rothschild-Hadassah-University Hospital to be affiliated construction will begin about July, according to Dr. Jacob J. Golub, New York, consultant to the committee. The new institution will be erected on a 25 acre plot on Mount Scopus overlooking the city. There will be three units, each three stories high: a 260 bed hospital, a graduate medical school and a nurses' training school. The teaching center will be named in honor of Dr. Nathan O. Ratnoff, New York, chairman of the American Jewish Physicians' Committee. Less than \$200,000 is needed to complete the building fund, it was announced recently by the fund committee of Hadassah, the Women's Zionist Organization of America, which is sponsoring the medical center.

**Society News**—The eleventh congress of the International Society of the History of Medicine will be held in September 1938 at Athens, Istanbul, Sophia and Zagreb. Subjects for discussion will be religious origins of hippocratic medicine, the hippocratic idea in modern medicine and medical folklore. At the tenth congress in Madrid in 1935 Dr. Gomoiu, Bucharest was elected president and Dr. Guart, Lyons, France, secretary.—Dr. Rudolph Matas, New Orleans, was chosen president of the International Society of Surgery at its meeting in Cairo, Egypt, Dec. 28, 1935. Dr. John Shelton Horsley, Richmond, Va. attended the meeting. The society will meet in Vienna in 1938.—The eleventh International Congress of Psychology will be held in Madrid, September 6-12.—The twenty-second annual conference of the National Association for the Prevention of Tuberculosis will be held in London, July 16-18.—An International Congress on Hepatic Insufficiency will be held at Vichy, France, Sept. 16-18, 1937, under the chairmanship of Prof. Maurice Loeper, Paris. The International Congress on Gastro-Enterology will be held in Paris, Sept. 13-15, 1937.—An International Sports Physicians' Congress will be held by the International Sports Physicians Association in Berlin, July 27-August 1, just preceding the Olympic Games.—The first International Congress of Sanatoriums and Private Nursing Homes will be held in Budapest in September.

### CORRECTION

**Marriage**—THE JOURNAL April 25, page 1510 reported the marriage of Dr. William Rudolph Hamsa of Iowa City to Miss Doris Sanborn of Scotia, Neb. recently. Instead the notice should have read Rudolph Alfred Hamsa, DDS, of Scotia, Neb.

## Government Services

### Office of Public Health Education Established

The U. S. Public Health Service announces the establishment of the office of public health education, under Asst. Surg. Gen. Lewis R. Thompson, chief of the division of scientific research. The purpose is to carry out experimental studies in health education. Its initial activities will embrace the training and instruction of young commissioned officers of the service, special instruction for educators, health officers and sanitarians from state health departments and from health departments of foreign countries and for other eligible persons, the making of studies of educational methods employed in various health agencies and in other fields of education, with a view to adapting the methods to its own purposes, and to developing new and improved methods, the making of experimental studies in mass adult education, through the use of the radio for the purpose of evaluating various methods of radio education, the filing of permanent records of available material to be a repository of authoritative information in the field of health education, preparation of a bulletin of current health information, primarily for the personnel of the service. The first copy of this bulletin, entitled "The Health Officer," has made its appearance with the May issue.

### Annual Report on Traffic in Narcotics

According to the annual report of the commissioner of the bureau of narcotics, U. S. Treasury Department, \$1,244,899 was appropriated to enforce federal narcotic drugs laws for the fiscal year ended June 30, 1935. During the year a uniform narcotic law, drafted and approved by the National Conference of Commissioners on Uniform State Laws at its annual conference in October 1932, was enacted in Kentucky, Louisiana, Rhode Island, South Carolina and Virginia. Florida, Nevada, New Jersey and New York had previously adopted this legislation. Since the report was written, twenty more states have adopted the law in its original or a modified form.

The annual report gives accounts of ninety-five seizures. The total quantity seized showed an increase of 51 per cent over the total for 1933. There is at present no lawful manufacture of prepared opium in the United States. The total quantity of morphine seized during the year was about 66 per cent less than that seized during the previous corresponding period. The illicit traffic in codeine has increased to a scale which demands notice. Up to the present, the report states, this traffic has been mostly supplied from Canada and is heaviest in the area surrounding Buffalo. Since Canadian authorities discontinued the indiscriminate sale of this drug at Fort Erie, North, Ontario, more drug addicts than usual have applied to the Buffalo City Hospital for treatment. Illicit traffickers rely increasingly on the Far East for supplies not only of prepared opium, but also of morphine, heroin, and even cocaine. The increasing use of the Central American countries and the West Indies as bases for smuggling to the United States has caused no little concern. All the Central American countries except Guatemala and Panama are so used, and in West Indian Islands, West End and Bimini are generally used. There were 158 charges of violation placed against vessels. Of fifty defendants presented for prosecution thirty-three were convicted and twelve acquitted. There were 4,742 persons reported for criminal violations, of these 1,833 were registered. Thirty-seven separate chemical analyses of morphine seizures, 110 analyses of heroin seizures and nineteen analyses of cocaine seizures were made to determine the percentage of purity. Physicians whose narcotic permits were revoked numbered nineteen for conviction, and nine for addiction. During the week ended Dec. 9, 1934 the federal bureau of narcotics conducted a national drive against violators of the narcotic drug laws, resulting in the arrest of 441 persons. The drug seized in most cases was heroin (diacetylmorphine), generally in highly adulterated form. By March 15, 1935, some 211 of these persons had been convicted and sentenced to imprisonment by either state or federal courts. To reduce the use of narcotics in race horses, state racing commissions cooperated by having special stables erected at race tracks for conducting tests by veterinarians and chemists to determine whether horses were drugged. Many of the states require at least two tests daily of horses selected by the stewards. During the calendar year 1934, a total of twenty-two thefts of order forms was reported and the unaccounted losses reported totaled 154. Growing cannabis was discovered in and around Denver, Colo., Atlanta, Ga., Jacksonville, Fla., Tulsa, Okla. and a small plot was discovered and destroyed within the city limits of Brooklyn, N. Y. In the San Joaquin Valley, California, alone about 4,000 pounds of marihuana was destroyed.

#### The Care of the War Blinded

St Dunstan's Hostel was founded for war-blinded men in 1915 by the late Sir Arthur Pearson and has had under care nearly 2,000 cases, while new cases still continue to come in. The average age of the men is a little over 45. It has been calculated that in twenty years there will still be 1,200 war blinded and that in forty years more than 400 may still be left. During the last few years there have been nearly 100 new cases—men who have only recently gone blind as the result of injuries in the war. Many have been due to mustard gas, and in the last two years fifteen such cases have been admitted. On the other hand, lacrimatory gas, though irritating to the eyes when discharged, does not seem to cause any permanent disability. Chlorine gas too, while dangerous to the lungs, does not seem to have been injurious to the eyes. Sir Arthur Pearson's main idea was to establish a hostel where blinded soldiers could be taught how to resume their places in civil life and, as far as possible, overcome their handicap. His enterprise has been a great success, largely because of the work of the welfare department which looks after practically every business, family and domestic need of each man when he is settled in his own home again. It supplies the craftsman with raw material tools and apparatus and skilled instruction. Through a special sales department it sells the work he produces. It also watches over his health and that of his family.

An institution which is performing a valuable service for the blind in general is the National Library for the Blind, the reconstructed premises of which have been opened by the minister of health. The library provides for 11,000 blind readers, of whom about 8,000 receive their books by mail. The number of volumes circulated averages 1,500 a day. The reconstructed premises will house 250,000 volumes. The library has at present 186,000 volumes, representing 15,000 complete books.

#### International Congress of Physical Medicine

The government has invited twenty-five countries to send representatives to the sixth International Congress of Physical Medicine, to be held in London May 12-16. Several countries—Belgium, France, Hungary, the Netherlands, Russia and the United States—have formed organization committees and will be strongly represented. The scientific and clinical aspects of physical medicine will be discussed in seven sections: (1) kinesitherapy, (2) hydrotherapy and climatotherapy, (3) electrotherapy, (4) radiology, (5) actinotherapy, (6) radiology and (7) the teaching and organizing of physical medicine in medical schools. The meetings will be held at the Royal Society of Medicine, the Hall of the British Medical Association and the British Institute of Radiology. There will be an exhibition of physical medicine apparatus at the College of Nursing. The president and chairman of the executive committee is Sir Robert Stanton Woods. The honorary president is Lord Horder. The secretary of the congress is Dr. Albert Eidenow, 4 Upper Wimpole Street, London W. 1.

#### Safeguards Against Poisoning

Mr. H. N. Linstead, a member of the Poisons Board, addressed the Medico-Legal Society on safeguards against poisoning. He said that 892 persons died from poisoning in Great Britain in 1934 while the average number of deaths was 815 in the last ten years. Apart from coal gas (which was responsible for 1,000 suicides annually) a spontaneous solution of

cresol was the most common poison used for suicide and was taken in 300 cases, hydrochloric acid came next, with ninety cases. The needs had been shown for additional safeguards against barbiturates. The number of analogues of barbiturals introduced into medicine ran into hundreds. Each was introduced as a safe hypnotic but soon appeared in the statistics of deaths from poisoning. Analysis of national health insurance prescriptions showed that about 1 per cent were for barbiturates. Fatalities due to them were not large but had increased, the majority were suicides and nearly all the remainder accidents. New legislation provided that they should be supplied to the public only on medical prescription.

#### ACCIDENTS IN MANUFACTURE AND SALE OF DRUGS

From time to time accidents occurred in factories in which pharmaceutical preparations were made and might give rise to widespread poisoning. A few years ago a mixture was made up in concentrated form of chloroform and strychnine. The chloroform was not dissolved in the mixture but remained at the bottom with the greater part of the strychnine dissolved in it. Owing to the control exercised by the manufacturer, no serious form of general poisoning resulted. Accidents had occurred from the sale of disinfectants in sauce or whisky bottles or even in milk jugs. They had now to be sold in sealed containers.

#### ACCIDENTS FOLLOWING MEDICINAL USE

When poisons were taken medicinally, two contributory circumstances to ill effects were idiosyncrasy and the cumulative effect of taking them over prolonged periods. The effect of the regular taking of acetophenetidin in producing toxic jaundice had led to its inclusion in the 'poisons list,' so that it had to be labeled with cautionary words. The recent attention to the part played by aminopyrine in producing agranulocytic angina had led to restrictions that would bar its use in proprietary medicines. The nitrophenols and nitrocresols were liable to produce untoward results even in medicinal doses unless the basal metabolic rate was determined. At least one death had occurred in this country from the use of one of these drugs for slimming. They could now be supplied only on medical prescription. New regulations were made to render more difficult the obtaining of poison for murder and to facilitate detection. All pharmacies had to be registered and all sellers of poisons had to be listed by the local authorities. This would facilitate the task of the police in tracing supplies. But provisions had not been made to prevent the theft of drugs from the physician's car.

#### Improvement in Radium Technic

At the British Institute of Radiology, Mr. H. S. Sontag described a technic for protecting the operator using radium. The radium is automatically conveyed by pneumatic pressure through a flexible tube while the operator remains at a distance until it is actually required. At the end of the tube is a lead cylinder 16 cm. in diameter with a conical cap for convenience of application. The radium is contained in a bobbin with rounded ends which is conveyed by the tube. When not in use the radium lies in a safe fully protected by lead, outside the treatment room. When required for treatment air pressure is applied to drive the radium along the tube. Its arrival is announced by the lighting of a small electric lamp. When the two-way valve is reversed the air in the apparatus is exhausted and the bobbin is conveyed back to the safe. The whole adjustment of the apparatus can be carried out in the absence of the radium which can be instantly brought into position when the treatment is begun. A further development of the system of pneumatic transference is that units of very small dimensions but containing large quantities of radium can be used with safety.

## Bradycardia of Digestive Origin

Five cases illustrating different types of bradycardia of digestive origin were reported by Marchal, Soulie and Roy at the Dec 20, 1935, meeting of the Societe medicale des hopitaux. These five cases demonstrated the following points

1 In Loeper's case the bradycardia was associated with ulcer of the lesser curvature of the stomach, but Marchal believes it can occur with ulcerations elsewhere, especially in the first portion of the duodenum. According to Loeper, a bradycardia can be found in cancer of the colon and in enterocolitis. Marchal observed a bradycardia in two cases of duodenal ulcer, in a case of chronic gastritis and in a case of dysenteric colitis. Thus a syndrome of neuritis of the left pneumogastric nerve gives rise to a sinus bradycardia in many different forms of ulcerative and nonulcerative gastro-intestinal lesions. The bradycardia in appendicular or colic lesions is probably due to some associated irritation of the right pneumogastric nerve.

2 The time of appearance of the bradycardia and of the attacks varies. In some cases it is observed during the period of development of the lesion and becomes more marked during periods of exacerbation of the pain or bleeding. In other cases the bradycardia precedes the localization of the ulcer and finally, as in Marchal's third case, its appearance was synchronous with that of the ulcer.

3 The type of bradycardia varies. In some, an attack may directly succeed a normal rhythm. Most commonly the bradycardia is of the sinus type without modification of the PR or AC spaces.

4 The oculocardiac reflex may be weak or of the normal type or even accentuated. The atropine and effort tests are followed by an acceleration.

5 The nervous complications usually appear in the guise of pseudoveriginous, syncopal or epileptiform attacks. The association of these with a well marked sinus bradycardia permits one to place these cases in the Stokes-Adams syndrome, but one must exclude such cases from this syndrome in which the syncope is due to severe bleeding.

## Serologic Diagnosis of Brucellosis

Julien and Laurent read a paper on the biologic diagnosis of human and animal brucellosis by flocculation of serum in the presence of a specific antigen, at the January 28 meeting of the Academy of Medicine. The diagnosis cannot be made from clinical evidence alone, only laboratory tests enable a positive or at least a presumptive diagnosis to be made. The three tests that have been employed are blood culture, the serum agglutination test of Wright and the intracutaneous reaction. Blood culture gives positive results only during febrile periods in from 10 to 15 per cent of cases. One must wait from seven to twenty days for positive cultures. The Wright test is the one most frequently employed. It happens that the use of antigens insufficiently tested and other technical difficulties results in the test being often reported as alternately negative and positive. At the recent brucellosis congress in Avignon a plea was made for standardization of the test. The sero-agglutination test becomes positive only after a certain interval (from 15 to 21 days) and becomes negative again a few months after termination of the febrile period. The intracutaneous reaction is not above criticism. The authors' flocculation reaction is carried out with the aid of an alcoholic *Brucella* antigen. The technic is simple, can be easily standardized and appears to be specific. Of 111 serums only thirty-nine from cases of proved human or animal brucellosis showed floccula-

tion. Serums from seventy-two normal individuals or those suffering from other diseases were all negative. The details of the technic of this new flocculation test are given in the Jan 28, 1936, issue of the *Bulletin de l'Academie de medecine*.

## Precautions Against Attack by Enemy Airplanes

During the past six months, the frequent trials of ear-splitting sirens make one realize that the civilian population of Paris is being trained to follow immediately the precautions outlined in a special circular distributed by the police department. In the corridor of every apartment a notice has been posted stating where to seek shelter in the neighborhood against poison gas and where the nearest fire station is located, which should be notified in case incendiary bombs have been dropped on a building. The bulletin of the police department states that no portion of France can be considered immune to aerial attack, although the larger centers of population will be involved first. A bombing airplane can transport from half a ton to a ton of bombs for a distance of 300 to 600 miles from their bases. Such modern engines of destruction can attain a speed of 150 to 200 miles an hour and can fly in all kinds of weather. Against explosive bombs a bomb-proof shelter must be sought. Against incendiary bombs every modern method of extinction is to be employed, against poison gas only a shelter especially equipped or a mask is of any avail. Attention is called to the fact that civilians should not become panicky when they hear the sirens because an elaborate system of passive defense has been organized which will go into action as soon as enemy planes are signaled approaching the frontier. Unfortunately, in inclement weather this is not easily accomplished. This was recently observed when trial attacks were made on London and Paris. Clouds so obscured the planes that a passive defense was practically impossible. The police department emphasizes that the enemy not only will attempt to destroy strategic points and large industrial points but counts on demoralization of the civilian population, hence the latter should be prepared to seek protection previously arranged. Every detail of how a civilian population can take precautions against aerial attacks is given in the police department circular.

## Professor Mocquot Appointed Professor of Gynecology

Professor Mocquot, at present associate professor in the Faculte de medecine of Paris has been appointed professor of clinical gynecology. This chair was formerly held by Prof. Jean Louis Faure, who retired when he reached the age limit in 1933, and more recently by the late Professor Proust, whose sudden death occurred in 1935.

## Hundredth Anniversary of Death of Ampere

Meetings were held at Lyons, March 5-8, to commemorate the death in 1836 of one of the founders of modern electrical science, Andre-Marie Ampere. The meetings were attended by physicists, electrical engineers and representatives of the industrial side of electricity from a number of foreign countries who read papers illustrating the applications of electricity. Ampere was born in a village near Lyons in 1775 and devoted his energies at first to a study of higher mathematics but later to all the basic sciences, especially physics and chemistry. In 1808 he was appointed professor at the Ecole polytechnique of Paris and in 1814 professor of physics at the College de France and member of the Institut de France, the latter one of the highest honors to be bestowed on a scientist in France. Ampere's most important contributions were his discovery of electrodynamics, which showed that there was an intimate relation of magnetism to electricity. He also maintained that the molecules of the body are the seat of constant internal indestructible electric currents, which act between each other and also toward ordinary current according to the laws of

electrodynamics, thus creating a starting point for present-day notions of electrophysiology and radiobiology. In 1820 Ampere called attention to the galvanometer to measure the intensity of a current by its action on a magnetized needle. Later he showed how electrical tension could be measured by the electrometer. He also discovered the astatic needle to eliminate the action of terrestrial electricity on the magnetized needle. Synchronously with Avogadro he called attention to the atomic theory. Thus the latter and electromagnetism have become the bases of many modern theories. Modern medical electricity owes a great debt to the genius of Ampere.

### Amenorrhea Among Girls in Work Camps

A large section of the young female population of Germany is lodged in the work service camps. The principal object of these camps is to indoctrinate the girls with the social and political ideals of the National Socialist weltanschauung. An equalization of city dwellers and country dwellers also is attempted. Since the medical supervisors of these camps have reported a great many cases of chronic amenorrhea, the question arises whether or not the camp regimen is in any way responsible. The gynecologist A. Mayer has expressed himself on this problem in "Erbarzt." Mayer points to the fact that in boarding schools and among servant girls, nurses, female students and female athletes, change of residence or surroundings frequently leads to suppression of the menses. He raises the question whether the *Arbeitslager* exercise an effect similar to that of any new environment or whether there is some particular influence in camp life. There are two causative complexes: (1) constitutional factors that previously existed and (2) conditional factors that originate in the *Arbeitslager*. Age is an important constitutional factor. The younger the girls the greater the incidence of menstrual irregularity. Mayer distinguishes among girls from differing environments: big city, medium sized and small town, open country. Examinations conducted by Koch in Leipzig show that the menarche begins early among girls of the larger cities and that during the last twenty years menstruation has come to begin from one to two years earlier than before. Further causes of amenorrhea are asthenic constitution, pulmonary tuberculosis and endocrine disorders involving the thyroid and pituitary bodies. The thyroid gland is held responsible for certain menstrual disorders as well as for a premature menopause. Moreover, according to Aschner, amenorrhea is more common among red haired women and also among those having marbled skin and those with debilitated sympathetic nervous systems.

Among the causes conditioned by residence at camp in addition to the psychological influence are climatic changes. Nothing definite has been determined with regard to climatic influence. Kustner has asserted that red light activates the sex hormone. Whether the change of diet leads to amenorrhea indirectly by avitaminosis is not known. It is hardly to be assumed, however, that sexual vitamins, as contained within certain plants, should be absent from the camp diet. The ergot content of flour, which in war time is a result of more complete milling conduces to 'wartime amenorrhea' certainly plays no part at present. Mayer regards the concept of an amenorrhea due to fattening as arbitrary. It has already been established that the same endocrine disturbance may lead simultaneously to an arrest of ovarian function, a suspension of the menses and an excessive deposit of fat. The question of an 'exhaustion amenorrhea' could be answered if one were able to observe such a disturbance in underexercised females following unaccustomed physical exertion. Suggestion appears to

play an important part among further possible causes of amenorrhea. Lack of privacy in common sleeping quarters at the camps certainly must give rise to a desire on the part of the camper to conceal this natural function. A powerful wish to keep menstruation from hampering one's participation in the activities and routine of the camp would act in like manner. It is recognized that voluntary influence may effect modifications in the cycle. In many regions such suggestion is connected with old symbolic customs. In Switzerland, for example, on the eve of great popular festivals, the young girls are wont to bind a bright colored ribbon about one finger or affect some other symbol in order that their participation may not be hindered by menstruation.

Perhaps the sum total of relevant somatic and psychic factors as determined by inquiries and examinations in the *Arbeitslager* for females may shed some light on the causes of the seemingly increased incidence of amenorrhea.

### The Ban on Schächten

The ban on *schächten* (slaughter according to the Jewish rite) which obtains in Germany as well as in other countries has meant a considerably reduced diet for those Jews who remain faithful to the letter of religious command. Consequently, institutions controlled by the Jewish religious community and hospitals in particular find it impossible to provide inmates or staff with abundant nourishment. According to the German legislation, warm-blooded animals must be stunned before slaughter. An electric current has frequently been used for rendering the animals senseless. If the full current is applied, as is customary, it is often strong enough to cause injury or death before the slaughter, properly speaking, has taken place. The German law does not prohibit the *schächtschnitt* (slashing of the animal's throat by the kosher butcher) as commanded by the ritual, if the animal has first been stunned. A section of Jewry is inclined to accept as kosher the meat of animals that have undergone stunning by electricity prior to slaughter by the *schächter's* knife. The utterance, before a continuation class for Jewish physicians at Frankfurt, of Dr. Gustav Oppenheim, directed the attention of the Jewish commission in Berlin for study of the *schächten* problem to the results obtainable with *electronarcosis*. Oppenheim has been able by means of an apparatus which he devised to produce long-sustained periods of narcosis in animals, which subsequently experience a complete *restitutio ad integrum*. This means that the beast may be stunned by electrical shock without any damage to its flesh. The proper religious authorities, however, have failed to understand. Perhaps the final word has yet to be spoken.

### Fate of the Prematurely Born

The program of health conservation which the Germany of today is carrying out has as its fundamental ideal the breeding of a superior race and the prevention of hereditarily diseased progeny. It should be to the interest of such a government to determine whether measures designed to preserve the lives of prematurely born infants are compatible with its political philosophy. An instructive article by Hans Henning has been published in the *Reichsgesundheitsblatt* entitled 'The Value of Preserving the Prematurely Born.' Six hundred and fifty prematurely born infants were observed at the children's clinic of the University of Frankfurt from 1925 to 1930. It was established that life expectancy was in direct proportion to weight at birth. The mortality of the premature infants in relation to weight at birth was as follows: less than 1000 Gm, 100 per cent; 1200 Gm, 98 per cent; 1500 Gm, 83 per cent; 2000 Gm, 48 per cent; from 2000 to 2500 Gm, 35 per cent. It was proved, however, that the developmental possibilities

of the surviving children were not conditioned by weight at birth. Follow-up examination of eighty-one children showed that beyond the sixth year of life no difference whatever was perceptible between the prematurely born and children born at full term. In infancy the prematurely born are especially likely to present umbilical and inguinal hernias, which, however, usually disappear as the musculature is strengthened. Almost without exception the children presented rickets. About 10 per cent showed defective intelligence and even in the mentally normal the beginning of speech and of walking came later than in children born at full term. Premature infants afflicted with syphilis almost all die. Although at the children's clinic 48 per cent of the patients admitted from 1914 to 1925 were syphilitic, the proportion was reduced to 23 per cent (or by more than half) from 1925 to 1930. Of further importance is the fact that children exhibiting retarded beginnings of speech were found in most instances to have been brought up in institutions. The monotonous environment of the orphanage lacked those stimulations to speech which are present in even the poorest family circle. There is no absolute connection between premature birth and premature death. Mortality in the first week is generally due to spinal and cerebral hemorrhages suffered during parturition. Since the question of the value of preserving the lives of premature infants can be answered in the affirmative, such preservation may be considered as within the scope of governmental policy.

March 17, 1936

### International Medical Week in Switzerland

The first "International Medical Week in Switzerland" was held at Montreux. This convention was promoted by the *Schweizerische medizinische Wochenschrift* and its editor, Prof A Gigon of Basel. The idea was to bring together in central Europe prominent foreign investigators and the leading medical scholars of Switzerland for informal professional cooperation and personal contacts. Switzerland, a neutral country, maintains five universities (besides several *hochschulen* and other separate faculties), which enjoy an excellent reputation. The Swiss universities have always been in the habit of calling foreign scholars to the professorial chairs. Also they have always emphasized the international importance of science. The total number of participants at the congress was more than 300, sixteen countries being represented. When one considers that this was the first such meeting, this attendance may be regarded as outwardly gratifying, all the more so in view of the unexpected obstacles which foreign participation encountered. These took the form not only of those stringent foreign exchange regulations in some European states which restrict freedom of intercourse beyond their own frontiers but of sudden demands and prohibitions in the matter of racial doctrine, which were based not on scientific proofs but on political considerations. These demands emanated from the German national fuhrer of medicine and were directed against the well known Viennese clinician Prof Julius Bauer, whose scholarly views on problems of race and genetics are so diametrically opposed to those of the present political leadership of medicine in the German reich. By intricate diplomatic negotiation, the ministries concerned were able to obtain an eleventh hour revocation of the ban on attendance at the convention, which had been imposed on German physicians. Still, such interferences are not conducive to good feeling, even in the case of a purely scientific congress.

The convention enjoyed the full approval and sponsorship of the Swiss government. The minister of education himself as representative of the federal council convened the gathering

and presided over the first session. The papers were submitted according to group, each daily session was devoted to a different topic.

The first day was dedicated to "General Therapy." Prof Sir Henry Dale of London discussed the "Pharmacology of Ergot." He spoke of the new alkaloids that have been isolated one after another in various quarters. A certain confusion still exists with regard to this question. Dudley and Moir isolated "ergometrine" in London. Stoll in Basel isolated "ergobasine." The isolation of an apparently similar alkaloid was recently reported from America. To all appearances, ergometrine and ergobasine are to be considered as identical substances. [The Council on Pharmacy and Chemistry (THE JOURNAL March 21, p 1008) has adopted the nonproprietary name "ergonovine" for the new oxytocic alkaloid from ergot.] After a lively discussion Dale and Stoll agreed on a joint examination of the substances in order that their identity might be finally determined. This was one of the important accomplishments of the convention.

Prof W Straub of Munich spoke of "One Hundred and Fifty Years of Digitalis Therapy." The glucosides of *Digitalis lanta* are formed in the same manner as those of *Digitalis purpurea* excepting that they are magnified by a residue of acetic acid. New glucosides to aid cardiac action can perhaps be obtained by the introduction of sugar into stearins. Straub emphasized the need for a completely organized pharmacology of the diseased heart.

The Berne surgeon Prof F de Quervain discussed "Scientific Bases for Goiter Prophylaxis."

The second day's session dealt with "Vitamins and Hormones." The Zurich chemist Prof R Karrer furnished a summary of the more recent developments in vitamin research. He stated that the customary, more or less sharp distinction between vitamin and hormone should be abolished. He pointed out that vitamin B<sub>1</sub> produces the hormone of growth in the lower fungi. In rats, mannose produces the provitamin for vitamin C, cevitamic acid. Tenuous distinctions also exist between vitamins and enzymes. The lines of demarcation between vitamins and hormones will become increasingly indistinct as our knowledge of these substances progresses.

Prof Friedrich von Muller of Munich spoke on "Recent Opinions on Obesity, How It Originates and How It May Be Combated."

Prof Ernst Laqueur of Amsterdam spoke on "Male and Female Hormones." In designating the action of sex hormones that exist simultaneously one might employ the term "synergy" instead of "antagonism." The following example supports this change. The activity of the male hormone in the seminal vesicle is increased by the presence of estrogenic substance. The older theory of counteraction between male and female hormones contains some elements of truth, the action of estrogenic substance on the prostate, for example, is hindered by a simultaneous and abundant supply of male hormone. Prof Emil Abderhalden of Halle spoke on "The Interdependence of Vitamic and Hormonic Needs in Certain States."

Prof H E Sigerist of Baltimore discussed "The Present Uneasiness in the Medical Profession." He raised the question of whether or not there is an actual plethora of physicians and concluded that, from an economic point of view, the supply is more than adequate, but insufficient if the extension of medicine into the field of individual prophylaxis and hygiene is considered.

The third day was dedicated to "Internal Medicine." The Parisian professor A Lemerre discussed septic pyemia produced by *Bacillus funduliformis*. This micro organism appears as an anaerobic saprophyte in the mouth, pharynx, intestine and genito-urinary canal. The bacillus is remarkable for its polymorphism and may produce sepsis. In several cases of

postanginal sepsis due to anaerobes observed at Paris, the causative agent was almost without exception *Bacillus funduliformis*. It attacks chiefly persons between the twentieth and thirtieth years.

Prof Egas Moniz of Lisbon next discussed 'Clinical Results from the Use of Cerebral Angiography,' a subject studied by him since 1927. In addition to its use in the localization of tumors (aneurysms and angiomas) the cerebral angiograph supplies information about the velocity of circulation, especially if several pictures are taken in relatively rapid succession.

In his newly constructed clinic Prof L. Michaud of Lausanne discussed kidney disorders. He answered the question of a relation between azotemia and chloremia by saying that no direct correlations between the two exist. He arrived at this conclusion on the basis of 190 cases, in which 1248 analyses were made.

The fourth day was devoted to "Pediatrics and Nutrition." Prof Pierre Nobecourt of Paris discussed 'Growth Insufficiencies.' Prof E. Feer of Zurich spoke on 'Specific Vegetative Neuropathy in Infants (Childhood Acrodynia), a disorder first described by him and called after him Feer's disease.'

'Cancer and Radiotherapy' was the topic on the fifth day. Prof I. Holmgren of Stockholm informed the group that he had been able to effect modifications in cancers of the stomach by the use of tuberculin and BCG vaccine. Large dosages of tuberculin were remarkably well tolerated.

Prof A. Rosset of Lausanne stressed the importance of functional radiotherapy. Therapeutic results, modifications of the sympathetic nervous system, for example may be achieved by means of the roentgen rays. Prof Emil Burgi of Berne spoke on "New Scientific Methods in Balneology."

The final day was devoted to contemporary problems. Prof F. Verzar of Basel discussed 'New Knowledge of Intestinal Resorption.' The adrenals regulate phosphorization. Since resorption of dextrose and galactose as well as of fat is effected by phosphorization, Verzar decided to investigate whether or not adrenalectomy would inhibit the resorption of fat and of dextrose. Experiments showed that in adrenalectomized animals resorption of fat was retarded in the same degree and resorption of dextrose almost to the same degree as after poisoning from monoiodoacetic acid or from phlorhizin. After injection of adrenal cortex extract, normal resorption of both dextrose and fat was resumed in the adrenalectomized animals. Prof C. Jimenez-Diaz of Madrid discussed metabolism in myopathic disorders. The Zurich psychiatrist Prof Hans W. Maier spoke on 'The Biology of Toxicomanias.' He outlined the symptoms of various addictions and the treatment and discussed the social and international aspects of the problem.

The regular attendance at the lectures was noteworthy. The audience was composed of specialists of all kinds in addition to a large number of general practitioners. Separate evening discussions were interpolated. The participants frequently would converse until midnight.

The first International Medical Week was a success. In compliance with the wishes of a large number of physicians the second International Medical Week will be held next September at Lucerne.

The management of the arrangements contributed to the success of the gathering: the official hospitality, the sumptuous outing financed by Nestle, and the hearty welcome accorded every one made it possible from the opening day for a friendly atmosphere to prevail.

#### The New Medical Clinic at Lausanne

Some time ago the New Medical Clinic was inaugurated at Lausanne with Prof L. Michaud as director. Several new institutes and clinics have been established in recent years. The Faculty of Medicine of Lausanne has aided in the modernization

of these institutions. Notable expenditures of money were made in many instances. Thanks to the sum contributed by the well known firm of Nestle, this new clinic was made possible. Located on the outskirts of the city the clinic has never been troubled for lack of space. Large airy rooms which insure absolute quiet are provided for the patients. Laboratory activities are as far removed as possible from the patients' notice. This is especially important, as it prevents the patients from feeling that they are objects of experimentation. There are 120 beds for patients, distributed over the first and second stories, on the third floor there are eighteen beds for private patients. The walls of the sickrooms are yellow. The clinic has a lecture room seating a hundred persons and a smaller room seating forty.

#### The Antivenereal Campaign

Prof Dr Edward Neuber, commissioner for the prevention of venereal diseases, stated recently that results may be obtained in the prevention of venereal diseases only if the work is done under uniform direction. The appointment of professors Lewis Nekam in 1917, Emerich Basch in 1929 and Edward Neuber in 1933 as ministerial commissioners are marks of progress in this field. Now the whole campaign against venereal diseases is centralized in the hands of these ministerial commissioners. The government reorganized the health administration in Hungary in 1924 and reformed the prevention of venereal diseases. At the meeting of the National Public Health Association in January 1925 an antivenereal committee was founded and was accepted by the ministry of social welfare and labor as a consultant body. The commissioner attaches great importance to the educational work and propaganda among the poor people and among youth. His principle is that public health laws succeed only when they meet with public understanding. It is absolutely necessary to provide medical consultation for every venereal patient and treatment for the poor. The antivenereal committee edited booklets and provided lantern slides on the symptoms of venereal diseases on the necessity of treating them and on their social importance. The commissioner was endeavoring to increase the number of dispensaries for venereal patients and to develop existing organizations in this field. These dispensaries are of great importance, and this importance will increase in the future when the new law becomes effective. Twenty-five dispensaries are now at work in the country, besides a greater number of free outpatient departments most of them work in cooperation with the National Social Insurance Institute, with the National Stephania Association and some of them with the National Public Health Institute. The obligatory premarital medical examinations encounter difficulties in this country.

Special importance is attached to periodic medical examinations in different age groups. The medical examinations carried on at Debreczin among school children of the first elementary class aimed to discover the frequency of syphilis, gonorrhea, tuberculosis, trachoma and other infectious diseases. In five years nearly 9000 school children were examined. Syphilis was found in from 4 to 5 per cent and pulmonary tuberculosis in from 20 to 25 per cent of the children. According to the new plans children with infectious diseases will be excluded from elementary schools. The periodic examinations will be made by the school physicians.

The antivenereal committee supported also the proposal made by Professor Guszmán of Budapest University for periodic blood analysis of pregnant women and antisyphilitic treatment if necessary.

## PREVENTION WORK

Dr Aladar Emodi, senior physician to the Teleia Association for the Prevention of Venereal Diseases, did pioneer work. The first social organization was established in Hungary in 1893, and this was the first movement of this kind in the world. The city of Budapest recognized the work of this association (called "Teleia") and offered it a yearly subsidy. The Teleia, under the management of Dr Emodi, surmounted many obstacles. The public at that time did not take the view that venereal patients were on an equality with other patients from the point of view of sickness benefit and drugs, but the law of 1907, proposed by Baron Szerenyi, chairman of the association, guaranteed equal treatment for venereal patients.

Venereal disease showed a great increase during the war, which stimulated the Teleia to double its energy. Dispensaries were established in several towns and effective propaganda was started. The films prepared by the association were attended by 150,000 adults, about 500,000 propaganda postcards and pamphlets were distributed. The monthly journal of the association has a circulation of 3,000 to 5,000 copies. The association reedited three booklets in popular style. Besides the Teleia, several similar associations were founded. The League Against Venereal Diseases and the Association for the Prevention of Venereal Diseases were short lived. Effective preventive work is done also by the National Social Insurance Institute and by other sickness insurance institutions, which, cooperating with other dispensaries, provide treatment for a great number of venereal patients. Remarkable work is done also by the Stephania Association, which provides dispensaries for the rural parts of the country. Propaganda is carried on also by the Museum of Social Hygiene, led by Dr George Gortvay, in permanent exhibitions in Budapest and in the country, and by lectures on Sundays in the museum.

## ITALY

## Meetings of Medical Societies

The Accademia delle scienze mediche of Naples met recently under the chairmanship of Professor Jappelli. Dr Becchini spoke on the relation between the emptying time of the stomach and the acidity of the gastric juice. The intensity of the acidity of the gastric contents can be determined by means of roentgen examination of the stomach. The emptying of the stomach after administration of 100 Gm of barium sulfate and 100 Gm of roasted meat is different in the same person when barium and meat are given simultaneously than when meat is given one hour after the administration of barium. The emptying time is less when barium and meat are given simultaneously than when there is an interval between their administration in persons with hyperacidity. The speaker advised the evaluation of the speed of emptying of the stomach, after administration of barium sulfate and meat without and with an interval, for determining gastric acidity in cases in which the stomach pump does not seem advisable.

Dr Susanna reported experiments in which he produced degeneration of the kidneys and liver of dogs and rabbits by prolonged administration of camphor. The examination of urine and the determinations of glycemia failed to show the presence of renal and hepatic disturbances during the life of the animals but the lesions were evident in microscopic studies of the organs. The pathologic alterations of the liver caused by the camphor were identical in dogs with and without biliary fistula. The speaker stated that his experiments support those who maintain that the administration of camphor is contraindicated in grave hepatic disturbances, diseases in which the oxygenation of the tissues is insufficient, diabetes and grave

forms of septicemia. The experiments prove also that camphor, administered either in small doses given for a long time or in large doses given for a short time, causes degeneration of a previously normal liver.

The Societa Piemontese di Chirurgia met recently under the chairmanship of Professor Bobbio. Dr Pescarmona discussed Comelli's sign in fracture of the scapula. The sign consists in the appearance, immediately after trauma, of a triangular tumefaction, which includes the entire area of the traumatized scapula and lasts for seven or eight days. The sign appears when the zone of spongy bone of the scapula is involved in the fracture provided, however, the integrity of the subspinal fascia is well preserved.

Dr Bobbio stated that the diffuse type of pelvic fibrosclerosis is of infectious origin, either genital or appendicular. The infection may be puerperal, gonococcal or tuberculous. Rectal disturbances predominate, frequently associated with vesical disorders and anorexia, weakness and cachexia. The differential diagnosis from malignant tumors is made by the chronic evolution of the disease and also by the clinical observations. The uterus is painful and fixed when it is felt by palpation and the rectum is deviated and stenosed. The prognosis is reserved. Medical treatment is indicated early in the development of the disease, but when changes in the rectum take place surgical treatment is indicated. Vaginal hysterectomy may be useful also in liberating the rectum. The speaker obtained satisfactory results from exploratory laparotomy followed by administration of medical treatment.

Drs Colombo and Romero reported results of studies made for the determination of chronaxia in twenty-three patients suffering from amyotrophy following articular infection and trauma. The speakers found that in all cases the chronaxia of the atrophic muscle is increased when the causal lesion is in evolution. The values of the chronaxia of the nerve are constantly normal.

## The Development of Hydrology

At a recent meeting of the *Corporazione della ospitalita*, the development of hydrology as a branch of medicine was discussed. Dr Rebucci asked for the establishment of a chair for the teaching of medical hydrology and also for the compulsory organization of centers for controlling the effects of hydrologic treatment in all thermomineral stations. The speaker emphasized the importance of preparing scientific literature about Italian mineral springs, in order to make their properties known.

Dr Vidau spoke on the importance of creating autonomous centers for the teaching of the subject. The speaker, having in mind that the establishment of a chair of hydrology meets economic difficulties at present, suggested the organization of courses the expenses of which could be covered by taxes collected, and also the organization of a high school of hydrology which would be supported by municipalities and other hydrologic centers.

Dr Quitadamo advocated the modernization of mineral springs and the reduction of expense in order to give persons of modest means the opportunity of receiving treatment when indicated.

## Congress of Dermatology and Syphilology

The Societa italiana di dermatologia e sifilografia will hold its thirtieth reunion in October under the chairmanship of Professor Tommasi. The official topics will be occupational dermatoses and the evaluation of social problems in Italy due to syphilis and gonorrhea. The second official topic will be subdivided into evaluation of the problem from a dermatographic point of view, evaluation of the problem from the point of view of production of work, economic burden of prevention, and treatment of syphilitic patients and syphilitic mothers.

## Marriages

OTTO FLOYD ROGERS JR, Bloomington Ind, to Miss Ruth Madelaine Wills of Connorsville, March 28

JAMES C DOYLE, Los Angeles, to Miss Jacqueline White of Spokane, Wash in Riverside, Calif, April 2

WALTER L THOMAS JR, Lynchburg, Va, to Miss Maisie Denhold of Durham, N C, March 10

NICHOLAS FLOYD ADAMS JR to Miss Margaret Bardelle Roberts, both of Baltimore April 24

NORVAN R INGRAHAM JR to Miss Louise Brown, both of Philadelphia, April 18

## Deaths

Carl Fredric Moll @ Flint, Mich Saginaw (Mich) Valley Medical College, 1899, member of the House of Delegates of the American Medical Association from 1926 to 1935 past president of the Michigan State Medical Society and the Marquette County Medical Society, an associate of the American College of Physicians, physician to the Michigan School for the Deaf, on the staffs of the Hurley Hospital St Joseph's Hospital and the Women's Hospital aged 64 died suddenly in Detroit, May 1, of acute myocarditis while in a taxicab

Herbert L Northrop, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1889 member of the Medical Society of the State of Pennsylvania, professor of surgery, and formerly dean at his alma mater fellow of the American College of Surgeons surgeon to the Hahnemann Hospital and Dispensary member of the consulting staffs of the Broad Street Hospital and of the Women's Homeopathic Hospital, aged 70, died, May 3, at his home in Melrose Park, of bronchopneumonia

Henry Denny Thomason @ Colonel, U S Army retired New York University of Pennsylvania Department of Medicine, Philadelphia 1882, entered the army as an assistant surgeon in 1903 veteran of the Spanish-American and World wars, was retired with rank of colonel in 1930 for disability in line of duty, formerly superintendent of the New York Homeopathic Medical College and Flower Hospital aged 77, died February 27, of coronary thrombosis

William Tweedy Getman @ Buffalo University of Buffalo School of Medicine 1901, assistant professor of obstetrics at his alma mater, fellow of the American College of Surgeons veteran of the Spanish-American War, attending obstetrician to the Buffalo General Hospital Buffalo City Hospital Millard Fillmore Hospital and the LaFayette General Hospital aged 59 died, February 20 of coronary occlusion and arteriosclerosis

Charles Crawford Hinton @ Macon Ga Johns Hopkins University School of Medicine Baltimore 1913 past president of the Bibb County Medical Society fellow of the American College of Physicians served during the World War laboratory consultant to the U S Veterans Administration and internist to the Middle Georgia Sanatorium, aged 47 died February 25, of angina pectoris

H Hershey Farnsler @ Harrisburg Pa Medico Chirurgical College of Philadelphia, 1904 member of the American Academy of Ophthalmology and Oto Laryngology fellow of the American College of Surgeons aged 57 consulting surgeon department of ophthalmology and otolaryngology Harrisburg Hospital, where he died, March 14 of acute nephritis

Christopher M Reyher, Gary Ind Northwestern University Medical School, Chicago 1906 member of the Indiana State Medical Association, fellow of the American College of Physicians formerly city health officer and president of the board of health aged 55 was killed February 12 when the automobile which he was driving was struck by a train

Albert Lee Coffield, New Martinsville W Va Eclectic Medical College Cincinnati 1911 member of the West Virginia State Medical Association past president of the Tyler-Wetzel County Medical Society formerly county health officer on the staff of the Wetzel County Hospital aged 50 died suddenly February 26 of cardiorenal disease

Thomas Rollins Marshall @ Major U S Army retired Wm Va, College of Physicians and Surgeons Baltimore 1893 veteran of the Spanish American and World wars

entered the medical corps of the army as a major in 1920 and retired in 1930 for disability in line of duty, aged 64 died, February 22, of coronary occlusion

Charles Franklin Watkins @ Billings Mont, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1901, fellow of the American College of Surgeons formerly city and county health officer and member of the city council surgeon to St Vincent's Hospital, aged 63, died, March 4, of bronchopneumonia

Tracy Earl Clark, Brooklyn Long Island College Hospital, Brooklyn, 1900, formerly instructor of chemistry at his alma mater professor of physiology and toxicology and assistant professor of materia medica, botany and pharmacognosy, Brooklyn College of Pharmacy, aged 69, died March 5, of carcinoma of the prostate

Joseph Ellmore Wier @ Evansville, Ind, Indiana University School of Medicine, Indianapolis, 1913, served during the World War member of the Associated Anesthetists of the United States and Canada, aged 52, on the staff of the Wellborn-Walker Hospital, where he died, March 16, of liver abscess and septicemia

Harry G Grable @ Kokomo, Ind, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906 past president of the Howard County Medical Society, on the staff of the Good Samaritan Hospital aged 53 died February 23, of coronary thrombosis, arteriosclerosis and gastric ulcer

Conrad Rowland Hoffman @ Glens Falls, N Y Albany (N Y) Medical College 1903 past president and secretary of the Warren County Medical Society, fellow of the American College of Surgeons aged 55 on the staff of the Glens Falls Hospital, where he died February 9, of carcinoma of the colon

George Daniel Balsbaugh @ North Manchester, Ind, Kentucky University Medical Department Louisville, 1904 president of the Eleventh District Medical Society, past president of the Wabash County Medical Society, aged 56, died, February 21, of coronary thrombosis and myocarditis

Carl A Bartholomew @ Martin Mich Detroit College of Medicine 1903 past president of the Kalamazoo Academy of Medicine for many years county coroner, aged 59, on the staffs of the Borgess Hospital and the Bronson Hospital Kalamazoo where he died February 15, of angina pectoris

Silas Rogers Corwith, Bellport, N Y, College of Physicians and Surgeons Medical Department of Columbia College New York 1883 past president of the Suffolk County Medical Society health officer of Bellport aged 77, died, February 26 of cerebral arteriosclerosis

Theodore Frank Foster, Pensacola, Fla, University of Cincinnati College of Medicine, 1921 at one time health officer of West Hartford Conn, formerly epidemiologist of the bureau of health of Knoxville Tenn aged 37, died, February 10, of bilateral polycystic kidney and uremia

Percy Augustus Perkins @ Memphis Tenn University of Virginia Department of Medicine Charlottesville 1908 fellow of the American College of Surgeons served during the World War on the staff of the Methodist Hospital, aged 52, died, February 20 of lobar pneumonia

William G Winter @ Holland Mich University of Michigan Department of Medicine and Surgery Ann Arbor 1906 fellow of the American College of Surgeons, for many years on the staff of the Holland City Hospital aged 52 died, February 9 of lobar pneumonia

Leland Vain Grady, Wilson N C North Carolina Medical College, Charlotte, 1913 member of the Medical Society of the State of North Carolina medical superintendent of the Carolina General Hospital aged 47 died February 21 in Bladenboro of pneumonia

Joseph Nicholas Bennett Garlick @ Schenectady N Y Albany Medical College 1904 president of the Schenectady County Medical Society, health commissioner of Schenectady aged 53 died February 17 in the Unitilla (Fla) Hospital of heart disease

Clifford Eugene Alexander, Duluth Minn University of Minnesota Medical School Minneapolis 1925 member of the Minnesota State Medical Association on the staffs of St Luke's and St Mary's hospitals aged 34 died in February of injuries received in a fall

John Morgan Smith Berkeley Calif University of Nashville (Tenn) Medical Department and Vanderbilt University School of Medicine Nashville 1893 aged 70 died February 8 in the Humboldt Hospital Albany of coronary sclerosis and myocarditis

**Charles H. C. Mills**, Charlotte, N. C., University of Maryland School of Medicine Baltimore, 1899, at one time professor of obstetrics and clinical gynecology, North Carolina Medical College, aged 68, died, March 5, of arteriosclerosis and heart disease.

**William Bernard Funk**, Chicago, Dearborn Medical College, Chicago, 1907, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910, aged 56, died, February 4, of chronic myocarditis and nephritis.

**John E. Cunningham**, Fowlerville, Mich., Detroit College of Medicine, 1894, member of the Michigan State Medical Society, aged 74, died, February 12, in St. Lawrence Hospital, Lansing, as the result of fracture of the hip received in a fall.

**Cornelius Francis Cooley**, Schenectady, N. Y., Georgetown University School of Medicine, Washington, D. C., 1934, aged 24, assistant resident to the Ellis Hospital, where he died, February 3, of appendicitis and peritonitis.

**Hugh Alexander McKay**, New Toronto, Ont., Canada, University of Toronto Faculty of Medicine, 1914, member of the American Psychiatric Association, superintendent of the Ontario Hospital, aged 51, died, February 14.

**Samuel Arnold Dorfmann**, New York, Baltimore University School of Medicine, 1898, aged 64, died, March 12, in the New York Post-Graduate Medical School and Hospital, of acute cholecystitis and bronchopneumonia.

**Robert Brodie Glasgow**, Burlington, N. J., University of Pennsylvania Department of Medicine, Philadelphia, 1878, aged 81, died, February 25, in the Odd Fellows Home, Trenton, of chronic myocarditis and arteriosclerosis.

**Clarence Wallace Flint**, Chicago, Chicago College of Medicine and Surgery, 1917, served during the World War, aged 46, died, March 10, in the Veterans Administration Facility, Hines, Ill., of pneumonia.

**Melvin Ellwood Beachy**, Grantsville, Md., University of Pennsylvania School of Medicine, Philadelphia, 1935, aged 31, died, January 29, in the National Stomach Hospital, Philadelphia, of sarcoma of the ileum.

**John Seymour Emans** & Gabriels, N. Y., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1892, aged 71, died, March 11, of cerebral hemorrhage and arteriosclerosis.

**Clarence Linden Lewis Jr.**, Richmond, Va., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1888, aged 71, died, January 28, in Biloxi, Miss., of angina pectoris.

**Charles Harvey Archibald**, New York, Jefferson Medical College of Philadelphia, 1890, aged 71, died, February 28, in Ashbur Park, N. J., of carcinoma due to x-ray burns of the left arm and chest wall.

**Marquis E. Daniel**, Honey Grove, Texas, Eclectic Medical Institute, Cincinnati, 1888, member of the state board of medical examiners, formerly mayor, aged 69, died, March 9, of coronary embolism.

**George Henry Bickley**, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1894, clinical professor of gastroenterology at his alma mater, aged 63, died, March 19, of heart disease.

**Robert Lawrence Piper**, Tyrone, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1892, for many years member of the board of education, aged 70, died, February 15, of uremia.

**Horace Emlen Westhaeffer**, Sunbury, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1875, aged 85, died, February 25, in the Mary M. Packer Hospital, of pneumonia.

**Mary E. Lapham**, Highlands, N. C., Woman's Medical College of Pennsylvania, Philadelphia, 1900, served during the World War, aged 75, died recently, in St. Augustine, Fla., of heart disease.

**Frank Sumner Lowell**, Cambria, Calif., Cooper Medical College, San Francisco, 1892, aged 71, died, February 11, in San Luis Obispo, of chronic pyelonephritis, cerebral thrombosis and uremia.

**Augustus Lucius Chase**, Randolph, Mass., Eclectic Medical Institute, Cincinnati, 1872, formerly member of the Board of Registration in Medicine, aged 86, died, February 28, of chronic cystitis.

**Augustus Wellington Chandler** & Rockford, Ill., Rush Medical College, Chicago, 1887, fellow of the American College of Surgeons, aged 75, died, March 24, of paralysis agitans.

**Oscar H. Kniffler**, New York, Rheinische Friedrich-Wilhelms-Universität Medizinische Fakultät, Bonn, Prussia, 1889, aged 72, died, January 27, of aneurysm of the aorta.

**Albert Anderson Long**, Kansas City, Mo., Ensworth Medical College, St. Joseph, 1913, veteran of the Spanish-American War, aged 65, died, January 19, of sarcoma of the femur.

**Joseph Clifton** & Memphis, Tenn., University of Nashville Medical Department, 1906, on the staff of the Methodist Hospital, aged 62, died, January 26, of heart disease.

**Edward Lyman Kingman** & Newtown, Conn., Yale University School of Medicine, New Haven, 1894, aged 64, died, January 1, of peritonitis and cerebral embolus.

**Hardin Davenport Irvan**, Gladewater, Texas, Jefferson Medical College of Philadelphia, 1909, aged 52, died, March 9, of injuries received in an automobile accident.

**Fred William McKibbin**, Oakdale, Calif., University of Vermont College of Medicine, Burlington, 1900, aged 61, died, February 17, of cerebral arteriosclerosis.

**Crittenden E. Keller**, San Antonio, Texas, Texas Medical College and Hospital, Galveston, 1881, aged 87, died, March 2, of arteriosclerosis and senile dementia.

**Horace W. Durnall**, West Chester, Pa., Columbian University Medical Department, Washington, D. C., 1878, aged 86, died, February 29, of chronic nephritis.

## Correspondence

### ADDISON'S DISEASE FOLLOWING ADRENAL DENERVATION

To the Editor—In THE JOURNAL, January 25, page 279, Dr J M Rogoff reported "Addison's Disease Following Adrenal Denervation in a Case of Diabetes Mellitus" While the diagnosis of Addison's disease was probably correct it should be pointed out that necropsy was not permitted and Dr Rogoff's statement that "the surgical manipulations apparently resulted in occlusion of blood vessels and degeneration of the adrenal cortex" is pure speculation Physiologists usually criticize post hoc propter hoc reasoning

The editorial (p 294), apparently based on Rogoff's one unverified case, proceeds to attack irradiation of the pituitary and adrenal areas as a treatment of hypertension and suggests by inference that this is irradiation of the kidneys, which is one effective way of producing hypertension" This statement is apparently predicated on the work of Page (*Am J Physiol* 112 166 [May] 1935) The writer appeared to be unfamiliar with Page's work or with irradiation used in the treatment of hypertension or with the significance of the different dosages used Page transplanted the kidneys to an abnormal position just under the skin From five to seven erythema doses of irradiation was then applied to each kidney We use 120 kilovolts, 3 milliamperes, 50 cm skin target distance, 2 mm of aluminum filter, five minutes On our machine this delivers 50 roentgens, about one ninth of one erythema dose and only slightly more than half as large as that used by dermatologists

It has been demonstrated that doses of x-rays large enough to damage the adrenals are not followed by any reduction in blood pressure or relief of symptoms of which hypertensive patients complain (*New England J Med* 211 952 [Nov 22] 1934) It has been proved experimentally, that with removal of one adrenal followed by the direct application of x-rays to the one remaining adrenal, it is necessary to use from ten to fourteen erythema doses before there is any sign of functional damage to the adrenal (*Am J Physiol* 93 219 [May] 1930)

Finally, there is now a series of something over 500 cases that have been treated by the method of irradiation that we use Approximately three out of four patients report symptomatic relief and a material reduction in blood pressure This has been true not only in our series but also in the hands of other workers who employ the same technic that we use So far not the slightest damage has been reported to the skin, the hair, the pituitary, the adrenals or the kidneys A number of patients have been under observation for more than three years, which seems sufficient time for symptoms of pituitary or adrenal damage to manifest themselves One case has come to autopsy The woman had had much larger doses than are ordinarily employed They were without material effect on her blood pressure Adenomas were found in the cortex of both adrenals There was no evidence of x-ray damage to the pituitary or adrenals No one can disagree with the editorial writer that the hazards of treatment should be less than the hazards of disease That principle was adopted before the irradiation method of treatment for hypertension was ever employed it has been consistently followed at all times

JAMES H HUTTON MD, E E MADDEN MD  
M J HUBENY, MD Chicago

{NOTE—The letter of Drs Hutton Madden and Hubeny was referred to Dr Rogoff, who replies }

To the Editor—The comments by Drs Hutton, Madden and Hubeny on my paper of January 25 and on the editorial in the same issue of THE JOURNAL impress me as an unconvincing clinical argument in favor of a risky empirical practice The

interpretations of the literature indicate an inadequate comprehension of the physiologic premises Page (*Am J Physiol* 112 166 [May] 1935) obviously displaced the kidney to a superficial position because he desired to irradiate only the kidney and to avoid exposure of other organs to irradiation Irradiation of the 'adrenal region' would include the kidney, which as Page showed, can produce hypertension Baird Lingley and Palmer (*New England J Med* 211 952 [Nov 22] 1934) did not claim that they damaged or attempted to damage the adrenals Pertinent interpretation of their paper should be made from their own statements that hypertensive patients are very suggestible, that there are marked spontaneous variations both in blood pressure and in the symptoms of patients with essential hypertension' Their conclusion reads 'Eight patients with essential hypertension in the late stages of the disease have been treated by roentgen radiation over pituitary or adrenals or both In the dosage used, no strikingly favorable effect on blood pressure or symptoms has been noted' Rogers and Martin (*Am J Physiol* 93 219 [May] 1930) irradiated the remaining adrenal, under anesthesia in unilaterally adrenalectomized dogs They observed that adrenal insufficiency may develop, even with smaller doses appearing some time after irradiation They also review literature of reliable experimental work by competent investigators on the great susceptibility to injury by roentgen irradiation of the mucosa of the alimentary tract, the kidneys, the pancreas and other organs

In view of the present inadequate knowledge concerning possible delayed (or immediate) injury to important structures roentgen radiation in any effective dose cannot be considered an indifferent procedure' Incidentally since experimental evidences are being considered I may call attention to the paper by La Barre (*Sang* 7 487 1933), who contends that small doses cause an increase in epinephrine secretion from the adrenals If so, this would certainly be anything but desirable or helpful in a patient with hypertension

The reference by Drs Hutton Madden and Hubeny to the diagnosis of Addison's disease, in my paper, as 'probably correct' and to my interpretation of the adrenal cortical damage as 'pure speculation,' because an autopsy was not permitted, is interesting Their implication that not the slightest damage to the adrenals pituitary or the kidneys occurred following roentgen irradiation is apparently not considered "pure speculation" Shall it be assumed that this is based on autopsy in each of the 500 cases mentioned and not on post hoc propter hoc reasoning' It would be a valuable contribution if they could suggest a more tenable explanation than mine for the cause of Addison's disease in the case under discussion I suggest a more careful perusal of my paper and of the article (reference 2) cited by me That may aid in a better understanding of the production of adrenal cortical insufficiency through traumatic and circulatory factors which lead to irreparable degeneration and also of the relation of such factors to serious or fatal adrenal insufficiency (e g, Addison's disease)

The alleged subjective improvement offered as the final and only proof of the value of roentgen irradiation of the pituitary and adrenal regions in hypertension is no more convincing than patients testimonials in the case of certain cancer cures faith cures or cures of rheumatism by toe twisting The report on Addison's disease following adrenal denervation in a case of diabetes mellitus was published by me primarily, as a warning against possible serious consequences of interfering with an indispensable organ especially when such a procedure is based on hypothetical concepts Obviously the author of the editorial in THE JOURNAL was guided by the same motive It seems evident that my report and the editorial recommendations of caution are timely, as expressed in the numerous personal communications received by me from readers of THE JOURNAL

J M ROGOFF MD Chicago

## THE DUCTLESS GLANDS—A DISCLAIMER

To the Editor —In the April issue of the magazine *Esquire* appeared an article by George Antheil on the ductless glands in which my name was mentioned. Mr Antheil is a former patient who became much interested in endocrinology. He read everything he could on the subject and made himself acquainted with some of the concepts of the field. Early this year he told me that he was contemplating writing an article on the ductless glands for *Esquire*. I told him that he would display the audacity of ignorance in writing such an article for any magazine, and that I was sure that it was bound to be full of inaccuracies and absurdities. He then asked me whether he might use my name, either my first or my last, if he decided to write such an article on his own responsibility, and I definitely refused permission. I was under the impression that our single conversation on the subject had put a stop to the writing of the article and I was astonished to hear that it had been written and published. On reading it I found it to be replete with preposterous inaccuracies and misstatements, not only scientific, but also personal. I wish to emphasize the following:

1 I did not see this article when it was written or before it was published.

2 I strongly opposed the writing of such an article.

3 There is not a single social occasion referred to, involving either men of genius, pugilists or dancers, that is correctly depicted, and the whole can be referred to politely only as "fictionized autobiography."

LOUIS BERMAN, M D, New York

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

## TUBERCULOSIS IN PREGNANCY

To the Editor —Please discuss the proper management of a pregnancy and labor of a tuberculous tertipara in the sixth month of pregnancy. She first knew of her condition three years ago. At present she has no cough fever or sputum; she has a good appetite and is gaining from 4 to 6 pounds per month. Roentgen examination shows an exudative productive lesion of a large area of the right upper lobe. On auscultation there are fine crepitant rales in the infracavicular region. Is it absolutely necessary to deliver with forceps? How long should she remain in bed during the puerperium? Is nursing contraindicated? Should BCG vaccine be used in the infant? Please omit name.

M D New York

ANSWER —Phthisiologists generally believe that the course of pregnancy and labor is only slightly effected by pulmonary tuberculosis. It is imperative, however, that a patient with pulmonary tuberculosis be under the care of both an obstetrician and a phthisiologist. Furthermore, the care on the part of the latter should continue for at least six months after delivery. Since this patient has no fever or cough or loss of weight, the prognosis is good, but in spite of this she must be carefully watched. When she goes into labor, special efforts should be made to conserve her strength, to diminish pain as much as possible and to eliminate if possible the second stage without harm to mother or baby. Hence as soon as pains are regular and strong, analgesia should be administered in the form of morphine, sodium amylal or similar drugs. As soon as the cervix is completely dilated and effaced the baby should be delivered with forceps, provided the head is engaged. In primiparas an episiotomy should be made. When the delivery can be accomplished by an easy low forceps delivery, direct infiltration anesthesia with 0.5 per cent procaine hydrochloride should be used. Otherwise ethylene-oxygen or nitrous oxide-oxygen should be used for the forceps delivery. All bearing-down efforts must be avoided in multiparas as well as in primiparas. Special hygienic care is important immediately after labor. Women with pulmonary tuberculosis should not nurse their babies; hence the breasts should be bound up snugly and fluids restricted for a few days. Nursing is prohibited both because it is a severe strain on the mother and also because it may be a means of infecting the new-born child. The length of time a patient should remain in bed after delivery depends

on her general physical condition. If there is no elevation of temperature, two weeks may be sufficient, but if fever is present the patient may have to remain in bed for many weeks and months. There is no need to use BCG vaccine in the infant.

An excellent exposition of this subject may be found in "Gynecological and Obstetrical Tuberculosis," by E. M. Jamieson, Philadelphia, Lea & Febiger, 1935.

## PREVENTION AND TREATMENT OF BRUCELLA ABORTUS INFECTION

To the Editor —Owing to the fact that several herds of cattle in this community are infected with *Brucella abortus* I am deeply interested in learning all that I can about this disease in stock as well as its effects on the human patient. 1 Will pasteurizing infected milk at 140° F for thirty minutes render such milk safe for human consumption? 2 What is known concerning the length of time these organisms can live in infected pastures where they are exposed to the sunlight and heat of summer and the freezing temperatures of winter? 3 A rather prominent dairy man in one of our larger centers is credited with the statement that butter made from infected milk quickly loses its infectivity because of its salt content. Is there any truth in this statement? 4 Am I correct in saying that when an infected bull is removed from a herd the infected cows will immunize themselves? 5 Also that an infected cow that has been given vaccine treatment over an adequate period also apparently returns to normal so far as giving birth to normal term calves? But the point in question here is whether these animals act similar to a human typhoid carrier and continue to throw off the infecting organisms causing undulant fever or whether the germs are entirely eradicated from the excreta. 6 Is the disease transmitted from the mother to the calf in cases of treated cows or in those that have apparently immunized themselves? 7 Could the consumption of infected milk by a pregnant woman cause abortion? 8 Are there any known methods of ridding an infected pasture of this contagion? 9 What is known relative to birds, rabbits and other animals transferring the disease from one locality to another? 10 Relative to therapy for human beings I have recently learned of a new treatment consisting of giving the undulant fever vaccine to a non-infected donor and then using the donor's blood or serum to treat the infected patient. I would appreciate a description of this method and your opinion as to its value as compared with the direct method of treating the infected patient with the undulant fever vaccine. Kindly omit name.

M D Missouri

ANSWER —1 Pasteurization of milk at 140° F for thirty minutes will destroy *Brucella* organisms.

2 C. P. Fitch (Report of Experimental Work in the Control of Bovine Infectious Abortion, *J. Am. Vet. Med. Ass.* 75:215 [Aug.] 1929) of the University of Minnesota states that *Brucella* organisms are not long lived outside the animal body; he believes that physical contact, especially "licking," is the principal way by which this infection is conveyed from animal to animal in the barn and paddock. In the pasture the aborted fetus and resultant contaminated food also become important factors in the spread of the disease.

3 C. M. Carpenter and Ruth Boak (*Brucella Abortus* in Milk and Dairy Products, *Am. J. Pub. Health* 18:743 [June] 1928) inoculated butter, prepared from pasteurized cream, with *Brucella abortus*, the salt content of the butter was 1.5 per cent. The organisms were still viable after 142 days of refrigeration at 46.4° F (8° C). C. P. Fitch and Lucille M. Bishop (Presence of Bacterium *Abortus* Bang in Raw Milk Butter and Ice Cream, *Proc. Soc. Exper. Biol. & Med.* 30:1205 [June] 1933) prepared butter with cream collected by gravity separation from the milk of cattle known to be shedding *Brucella abortus*. One half of the butter was salted (3 per cent) and one half was not salted. *Brucella abortus* was isolated from the salted and unsalted butter and from the buttermilk. These observers also recovered *Brucella abortus* from ice cream prepared from cream known to be naturally infected.

4 No.

5 The use of vaccines containing living *Brucella* organisms has been largely abandoned because of the danger of infecting cattle with the living organisms. Many cows continue to eliminate *Brucella* organisms in the milk for many months after all clinical evidence of the disease has disappeared.

6 If segregated from infected herds soon after birth, more than 90 per cent of the calves born from infected dams will become negative to the blood tests at from 3 to 6 months of age. This apparent immunity of calves to *Brucella* infection provides an opportunity to build up clean herds from the calves of infected animals.

7 Yes.

8 No accurate information is available.

9 No accurate information is available.

10 It is conceivable that the production of passive immunity by repeated injections of *Brucella melitensis* (*abortus*) vaccine in a noninfected donor might supply sufficient immune bodies to produce a favorable influence on the course of the disease following the transfusion of such blood to a patient with brucellosis. Vaccine therapy of patients with active brucellosis appears to produce a favorable influence in the majority of cases.

## TREATMENT OF OILY SKIN

To the Editor—Is there any special diet that influences excessive oiliness of the skin and scalp? Any suggestion as to local application will also be appreciated. Please omit name and address.

M D, Texas

ANSWER—There is no doubt that the restriction of fats and carbohydrates will lessen in some degree the production of sebum, but it is never sufficient alone to correct oversecretion. The patient must be examined thoroughly and any underlying disorder, such as anemia, constipation or focal infection, corrected.

Washing the face with hot water and soap, applying hot towels for ten minutes or more, then cold water and a brisk rub has a good effect. It should be done at least once daily, better both morning and evening. This with the use of a face powder containing 1 or 2 per cent sulfur or 3 per cent salicylic acid may be sufficient. If not, lotio alba (sulfurated potash and zinc sulfate, of each 2 Gm in 60 cc of rose water) may be applied at night after the washing and hot packs. This is to be shaken, dabbed on and allowed to dry. In the morning the face is washed as usual with soap and water. When the face becomes dry and scaly, whether generally or, as often happens, about the angles of the mouth, treatment must be suspended on the scaly area. If sulfur is not well borne, salicylic acid from 1 to 3 per cent, may be used in alcohol.

Ultraviolet exposures daily or every other day, or sun baths, have a decided drying effect. The risk of increased freckling or tanning must be taken. It is temporary. The same may be said of roentgen treatment, which in divided doses of from 37.5 to 75 roentgens each week is the most powerful of all methods and gives the most lasting effect. It should not be carried further than a total of three erythema doses (900 roentgens) for fear of late untoward effects.

For the oily scalp, lotio alba, which here may be used in double strength, 4 Gm of each of the ingredients in 60 cc of rose water, may give prompt amelioration. It should be well shaken, put on the scalp with a medicine dropper, and rubbed in with the fingers. The salicylic acid alcohol may be used in the scalp with good effect, the strength increased to 5 or 10 per cent. Ether, 10 or 20 per cent, may be added to dissolve the grease, which can be removed to some extent by rubbing the scalp with a paper towel. Frequent shampooing once or twice a week is called for. In spite of the fact that brushing and massage bring out sebum from the follicles, they should not be neglected, for their aid in increasing circulation is invaluable. Especially is this true in cases in which the hair is falling too rapidly. Sunlight exerts a beneficial effect, as does ultraviolet radiation. Going without a hat in a sunny climate or daily exposures to ultraviolet rays will be beneficial.

## PHLEBITIS

To the Editor—I have a case of severe phlebitis in the right leg which I have treated by rest, slight elevation of the leg and heat from an electric bulb. Could you please tell me if there is any other treatment that I could use ambulatory or otherwise? Please omit name.

M D Rock Island Ill

ANSWER—The treatment of thrombophlebitis in the acute stage is absolute rest in bed, elevation of the involved extremity and the application of heat, either by radiation or by moist hot packs. When the systemic temperature is no longer elevated and when edema and tenderness over the vein have disappeared the patient may be allowed out of bed. This period of active treatment is a variable one but rarely exceeds three weeks and is usually only a week or ten days. There is no value and perhaps considerable harm in keeping the patient in bed for a long period after he has phlebitis. From the clinical standpoint possibilities of detachment of the thrombus with subsequent pulmonary infarction or embolism are no greater almost immediately after the temperature is normal and edema and tenderness have disappeared than after a much prolonged period of rest in bed. After the condition is satisfactory enough to allow the patient to be up the sole problem of treatment is one of adequate support to prevent edema. The cloth bandages ordinarily used for this purpose are usually insufficient. Most satisfactory is a pure rubber bandage of moderate weight which is 3 inches wide by 15 feet long. This should be applied over a hosiery stocking beginning with two turns about the foot, making a figure eight about the ankle, and progressing up the leg to just below the knee. Such a bandage should be applied tightly enough to prevent edema and loosely enough so that it does not interfere with circulation, the symptoms of which are numbness, tingling coldness and excessive cyanosis of the toes. The bandage should be removed at midday and it is advisable ordinarily, for the patient to lie down for a while. It is then

reapplied over a dry stocking, and this procedure is repeated in the evening if the patient is active at this time. If he is inactive, he may lie or sit with the leg elevated.

Approximately one day of every month is used as a test period. The patient goes about normal activity without the use of the bandage. If edema occurs, it is necessary for him to resume the use of the bandage for another month. The bandage should never be discarded permanently until edema does not occur after ordinary activity. The period over which it is necessary to wear a bandage varies from two or three months to an indefinite number of years. If edema in the extremity is prevented by adequate bandaging, there will not be any subsequent complications, such as varicose veins, ulcers, stasis dermatitis, and lymphangitis.

## INCUBATION PERIOD IN MENINGITIS

To the Editor—How long from the commencement of the attack of epidemic cerebrospinal meningitis may the disease be contracted from the patient? What is the relative standing of the meningococcus serum and the more recently introduced antitoxin in the treatment?

THOMAS J TUDOR M D Norton Va

ANSWER—It has been estimated that the average time for meningococci to remain in the nasopharynx is about two weeks. It is probably on this basis that some states have established a minimum quarantine period of fourteen days for patients with epidemic meningitis. Meningococcus carriers are also often found to be free from the organisms within approximately two weeks. However, persistent carriers are occasionally found who continue to harbor the organisms for a period of months.

Excellent results in the treatment of meningococcal meningitis may be secured with the use of either antimeningococcus serum or meningococcus antitoxin provided the remedy chosen is given intravenously in sufficiently large doses.

Some reports have suggested that fewer complications occur among antitoxin-treated cases than among patients who are treated with one of the standard serums.

## HISTAMINE IN BLOOD

To the Editor—Kindly suggest a good chemical method for the quantitative determination of histamine in blood. Please omit name and address.

Ph D South Carolina

ANSWER—There is no good chemical method for the quantitative determination of histamine in blood. The presence of histamine is determined by the Pauly diazo reaction. A relatively simple procedure is described by MacGregor and Thorpe in the *Biochemical Journal* 27 1394 (No 5) 1934. In this test 1 cc of the solution to be tested is mixed with 1 cc of 0.5 normal sodium carbonate and 2 cc of a fresh diazo reagent is added. The latter is prepared by mixing equal volumes of 0.125 per cent *p*-nitramine in 0.1 normal hydrochloric acid and 0.37 per cent sodium nitrite. A reddish yellow color forms which reaches its maximum intensity in one minute. This color can be compared with permanent standards in a colorimeter if a quantitative estimation is desired. The method will determine as little as 0.01 mg of histamine. Other substances, such as histidine and tyrosine, also give the test. Proteins and ammonium salts interfere. The removal of these substances is time consuming and requires considerable skill to avoid loss of histamine.

Histamine may also be isolated by electrolysis (MacGregor and Thorpe) and determined by physiologic assays. The fall in blood pressure of an etherized cat is compared with the drop produced by a known quantity of histamine.

## TOXICITY OF CARBON TETRACHLORIDE

To the Editor—What information do you have on the toxicity of carbon tetrachloride when used to remove adhesive tape from the skin? When used in this manner is this material toxic excluding the local irritating effect? Please omit name.

M D

ANSWER—Chemically pure carbon tetrachloride is much less toxic than the impure drug but still four times as toxic as chloroform. Severe intoxications have occurred after its use as a dry shampoo for extinguishing fires and for dry cleaning. It is suspected that the toxic effect of some shoe dyes has been due to carbon tetrachloride rather than to other chemicals that have been blamed. As with chloroform the toxic effect is cumulative, so that small amounts repeated oftener than once in ten days even though they produce no immediate symptoms of intoxication may eventually cause serious damage to the liver. Calcium deficiency increases susceptibility to these chlorine hydrocarbon compounds. If a nurse is occupied with

dressings for several hours a day, even though the room is well ventilated, the use of carbon tetrachloride had best be avoided. See Tomb, J W, and Helmy, M M. The Toxicity of Carbon Tetrachloride and Its Allied Halogen Compounds (*J Trop Med* 36 265 [Sept 15] 1933)

#### ABNORMAL WHITE BLOOD CELL COUNTS

*To the Editor*—Recently I attended a boy 16 years old who had lobar pneumonia and whose white blood count was so high that it could not be counted with the ordinary white pipet mixture. The red pipet was used and the dilution was 1:200 by sucking the blood up to 0.5 and the diluting fluid up to 101 and then the cells were so numerous that it was almost impossible to count them. In using the medium power and counting one of the larger corner squares on the counting chamber and multiplying this by 62 and then multiplying this result by 10 for the dilution, the number of white cells was 8,896,000. I have been doing blood work for years and know that my method was correct but I have never seen anything like this and can find nothing like it in the books. Please inform me in what manner I could have made a blood mixture so that the white cells could be counted and also what you think of this excessive count. Many counts were made and they were all alike. Kindly omit name.

M D Minnesota

*ANSWER*—White counts of such a degree have not been recorded in medical literature. Was the presence of such an abnormal count confirmed by means of a stained blood smear? One of the most common sources of error in obtaining such counts is the presence of mold in the diluting fluid. Mold grows rapidly in an acetic acid diluting fluid and may easily be mistaken for leukocytes under low power. This can be avoided by the use of fresh diluting fluid or by the addition of thymol or other preservatives to the diluting fluid. If any of the diluting fluid is left it would be advisable to examine it under the microscope to rule out the presence of mold. In counting blood with high white counts, the red counting pipet is used, a dilution of 1:200 being made. The average counts of the corner fields are then multiplied by 2,000.

#### POSSIBLE DEMENTIA PARALYTICA

*To the Editor*—A man aged 48 weighing 150 pounds (68 Kg.) a railroad brakeman has had unsteady gait and has had to watch his feet for some time. When seen Oct 6 1935 he had had a spell in which there were incoordination, illusions and more or less muttering speech. The blood pressure at that time was 140 systolic 78 diastolic. The knee jerk was absent and light reflex was absent but otherwise the physical examination gave apparently normal results. The blood Wassermann reaction was 4 plus no spinal test was made. I have proceeded on the assumption that the condition is a neurosyphilis and am giving tryparsamide 2 Gm intravenously at weekly intervals. Now my questions are: What should I give him as a rest from the present treatment and how long should I keep it up? The literature available to me gives such a number of drugs that I am at a loss to know which is best. Will you kindly tell me if I am correct so far and how to proceed further? Kindly omit name.

M D Ohio

*ANSWER*—The diagnosis of this case is not neurosyphilis in the general sense. The patient probably has dementia paralytica, for which there is a specific remedy. He should be given a course of artificial fevers by means of malarial inoculations following which tryparsamide should be used. If malaria is not available, enough typhoid vaccine should be used intravenously to raise the temperature to 104 or 105 F in twelve separate treatments separated by two or three days' rest.

#### IMMUNIZATION AGAINST DIPHTHERIA

*To the Editor*—At a recent medical meeting at Dallas Texas one of the distinguished and competent speakers suggested protecting children from diphtheria (by one of the three most used materials) at the age of 18 months to 2 years instead of the 6 months to 1 year suggested by all literature that I've read during the last three years. This was a distinct surprise to me as well as to many others with whom I discussed his advice. With the published reports in view it seems to me to be had teaching even if it should become necessary to reprotect.

J D Michie M D Childress Texas

*ANSWER*—Most infants at birth are not susceptible to diphtheria. This is because of antitoxin present in the blood received from the mother. As the end of the first year of life is approached this antitoxin, for the most part, has been eliminated.

It is believed that there is greater antigenic response when little or no immunity exists than when partial immunity is present. For this reason it seems best not to administer toxoid before the twelfth month of life.

Diphtheria is infrequent under 1 year of age. From 1 to 2 years it is not rare. Therefore, it would seem better to immunize at 1 year than to wait until later unless one can have absolute assurance that the child will not be exposed to diphtheria in the meantime.

#### SENSITIVITY TO LIGHT

*To the Editor*—I have a patient who is hypersensitive to the ultra violet. She gets blistered, nervous, swollen and very toxic from the slightest exposure to the sun. Two years ago she had an excessive treatment with a General Electric house lamp and the hypersensitivity has been the result. I understand that she develops hematomorphyrin which I have treated with intravenous sodium thiosulfate but she still burns as easily as before. I will appreciate it if you can give me some information for the treatment of such a case.

L S Besson Portland, Ore

*ANSWER*—The patient was no doubt sensitive to light before she was exposed to the house lamp. One type of sensitivity to light is caused by the presence of photodynamic substances in the blood or tissues. Of these substances hematomorphyrin is one.

The patient should be carefully protected from overexposure to light through the use of black or colored clothing, excluding blue, and through staying indoors on sunny days. The patients thrive better in a dark wet climate than in a dry sunny climate because of the fact that air moisture filters off some of the sun's rays at the violet end of the spectrum. The pathologic source of the hematomorphyrin production should be found if possible and removed. If this can be accomplished the patient should improve after a period of months.

#### SKIN INFECTIONS IN BLONDES

*To the Editor*—In an adequate series on my records, red haired people and light blondes show an unusual susceptibility to furuncles, carbuncles, respiratory infections and chronic hypochromic anemia. How do you account for this? Kindly omit name.

M D New Jersey

*ANSWER*—There are some reasons for a greater susceptibility to infections on the part of extreme blondes. Their skins are apt to be drier as well as of finer texture and thinner than ordinary skins. They are therefore more easily irritated by trauma as well as by sunlight or cold wind, and the slight inflammations thus inaugurated reduce the skin's resistance to infection. The dryness of the skin means that its protective layer of lipids is deficient, and this may coincide with a deficient power of producing resistance to infection.

One form of hypochromic anemia, chlorosis, is said to occur more often in blondes, but as the discussions of the etiology of the hypochromic anemias has become more thorough the reference to blondes has been dropped. Chlorosis has become a rarity, which cannot be said of blondes. No reference has been found to a greater tendency of blondes to respiratory diseases. The same can be said with reference to furuncles and carbuncles. It is up to the doctor to present his statistics.

#### PAIN IN LIMBS AFTER CEREBRAL THROMBOSIS

*To the Editor*—I have been bedfast since 1932 following a thrombosis which caused a paralysis of the left leg and arm. The pain has been almost unbearable. Blocking of the nerves gave me relief for a short time so I am looking for something to relieve me. I will appreciate any suggestions you may have to offer.

M D, Indiana

*ANSWER*—The description is too incomplete for a definite therapeutic suggestion. Assuming that the pain is in the paralyzed limbs and not due to constriction of peripheral vessels or to joint lesions, it is most likely due to involvement of the optic thalamus. If there is a real "thalamic syndrome" there should be some impairment of superficial and deep sensibility, especially in the distal parts, as well as some ataxia. However, if blocking of nerves gave sufficient temporary relief to suggest peripheral origin of the pain, one might consider such drastic procedures as chordotomy or sympathectomy. If the pain shows no tendency to decrease and resists reasonable doses of analgesic drugs, consultation with a neurologic surgeon would seem advisable.

#### SPINAL FLUID CELL COUNT IN MENINGITIS

*To the Editor*—I have had some dispute as to the cell count in the different types of meningitis and would appreciate your sending me the latest account with the nearest number prevalent in these different forms and upon what amount of fluid is this estimate made.

Doris Solomon RN New York

*ANSWER*—The nearest number of cells per cubic millimeter in cerebrospinal fluid in different types of meningitis is as follows: tuberculous meningitis, 150; purulent meningitis of any type, 2,500. One must remember, however, that in tuberculous meningitis the cell count may vary from 30 to 1,000 cells. Likewise the cell count in purulent meningitis may vary from 200 to 25,000 cells. As a rule, the earlier in the disease the lumbar puncture is done, the fewer cells the fluid contains.

One drop of cerebrospinal fluid suffices for a cell count.

## Book Notices

**The Diagnosis and Treatment of Diseases of the Peripheral Arteries** By Saul S Samuels A M M D Chief of the Clinic for Peripheral Arterial Diseases Fourth Division Bellevue Hospital New York Cloth Price \$3 50 Pp 260 with 51 illustrations New York Oxford University Press 1936

This book, by a surgeon, is concerned chiefly, as the author states in the preface, with treatment of diseases of the peripheral arteries. The author apparently did not intend that the volume should be a reference book, since many important contributions to the physiology, pathology and treatment of the diseases of the peripheral arteries are mentioned briefly or not at all and references in the text are not always included in the bibliography. The subject and author indexes are incomplete. The bibliography contains more references than are mentioned in the text. Raynaud's disease, erythromelalgia and arteriovenous fistula are dismissed with a few sentences, and nothing is said of the treatment of the last two mentioned conditions. Aneurysm and periarteritis nodosum are not mentioned. For these reasons the book cannot be said to be complete.

The author holds no brief for mechanical methods of diagnosis or evaluation of treatment except for the oscilometer, which is described in detail. He says that the skin thermometer "has furnished a playful apparatus to the dabbler in experimental therapy." Several students of arterial diseases have the same opinion regarding the oscilometer. The author appears to have the unique opinion that skin temperatures are of no value in determining changes in arterial circulation. He admits that the oscilometer is of no value in determining collateral circulation. Almost all physicians familiar with diseases of the peripheral arteries agree that determination of the skin temperatures under certain conditions is a valuable index of changes in the collateral circulation.

The chief value of the book is in the detailed presentation of the treatment of thrombo angitis obliterans and arteriosclerosis obliterans. Although exception might be taken to some of the statements regarding treatment which are clearly an exposition of the author's ideas, the results he reports are extremely good. The mainstays of treatment of thrombo angitis obliterans without ulceration or gangrene, according to the author, are absolute cessation of smoking, sitz baths, diathermy, postural exercises, intravenous injection of solutions of sodium chloride and intramuscular injections of tissue extracts. The author interdicts the use of warmed environmental air because of the danger of burns, but he does not mention commercially available appliances that obviate this possibility by thermostatic regulation of the temperature of the air and protection of the sources of the heat so that the extremities cannot come in contact with them. Since heat can be applied constantly by this means while the patient is in bed the appliances mentioned appear far superior to sitz baths, which the author recommends. He feels that contrast baths are dangerous but this is rather an unusual opinion. He believes that intermittent negative and positive pressure is attended with considerable danger but this opinion is directly opposite to that held by those who have used this method of treatment with reasonable care. The author does not favor intravenous injections of typhoid vaccine apparently because such injections may prove fatal. Other workers in this field have used this method of treatment with reasonable care in hundreds of cases without trouble. In considering sympathectomy the author says: "The fallacy of this form of treatment

remains in the fact that sponsors of these operations have placed too much emphasis on the vasomotor element of this disease." He seems to have overlooked the frequently repeated statement that sympathectomy is valuable only when vasospasm or incomplete vasodilatation can be demonstrated preoperatively. Diathermy is recommended without evidence that it increases circulation. It probably produces temporary vasodilatation which the author indicates is largely valueless when produced by other simpler methods. He states that the sitz bath is superior to immersion of an upper extremity in a hot bath for increasing circulation but he does not support his opinion with evidence. The author appears to have had much success with intravenous injections of solutions of sodium chloride, which he believes increase pulse amplitude and thus the collateral circulation, although it is obvious that an increase in collateral circulation is difficult to prove, since skin temperatures are not elevated by this treatment. His enthusiasm for this type of treatment is not well supported by experience in other medical centers.

When gangrene or ulceration occurs, the author recommends absolute rest in bed, cessation of smoking, intravenous injections of salt solutions, and application of antiseptic solutions wet dressings and anesthetic ointments, as indicated. Surgical conservatism is stressed. The author's ideas are minutely presented. One statement appears a bit emphatic: "It is no longer necessary to amputate a leg in thrombo-angitis obliterans because of impending gangrene as has heretofore been the practice." Many clinicians particularly interested in thrombo-angitis obliterans will be startled to know that amputation "has heretofore been the practice" for impending gangrene, but to those less experienced the statement is an emphatic and warranted denial of the necessity for performing amputation in such cases.

The author treats arteriosclerosis obliterans in much the same manner as he does thrombo-angitis obliterans except that when diabetes complicates occlusive arterial diseases attributable to arteriosclerosis, the presence of spreading infection necessitates amputation. The conservative use of amputation is again stressed as it is in the chapter on thrombo-angitis obliterans, but no figures are given. The low incidence of amputation in both thrombo-angitis obliterans and arteriosclerosis obliterans is remarkable but the author does not state the period of follow up.

The book is valuable for what it is—a clear exposition of the author's recommendations for treatment of thrombo-angitis obliterans and arteriosclerosis obliterans. It is unfortunate, perhaps, that many statements of vital importance are unsupported by evidence and that the author is frankly intolerant of or disbelieves observations made by others experienced in the treatment of vascular diseases.

**Die Hautkrankheiten. Ein Buch für Ärzte und Studierende.** Von Dr. Richard Rohrbach. Facharzt für Hautkrankheiten in Bremen. Paper. Price 20 marks. Pp. 393. Dresden & Leipzig: Theodor Steinkopff, 1935.

Rohrbach presents a book for physicians and students in which skin diseases are grouped on biologic rather than morphologic lines. The book is composed of a general part in which the various subjects are handled in much the same manner in which they are treated in the American textbooks, and a special part, divided into conditions of known etiology, under which is included the infectious skin diseases embracing a discussion of the pyoderms, fungous and parasitic infections and other infectious conditions of the skin and hereditary skin diseases in which the significance of heredity in dermatology is discussed. The latter is grouped into dominant and recessive skin diseases. Under dominant the author classifies epidermolysis bullosa hereditaria, ichthyosis vulgaris, ichthyosis congenita universalis, neurofibromatosis, Darier's disease, keratoma palmare et plantare hereditarium, acne vulgaris, prokeratosis, vitiligo and rosacea. Xeroderma pigmentosum is the only condition classed as recessive. The section on allergic skin diseases embraces urticaria, eczema (including infantile eczema), angioneurotic edema, prurigo, Hebra strophulus and serum sickness, and endocrine diseases of the skin under which are discussed Addison's disease, Simmonds' disease, impetigo herpetiformis, dermatitis dysmenorrhoeica, myxedema and acanthosis nigricans. Avitaminosis or deficiency diseases under which scurvy is grouped,

is further subdivided with hydroa vacciniforme and pellagra, grouped under the heading of avitaminosis with increased light sensitivity. Diseases associated with disorders of metabolism are discussed and include the entities psoriasis, xanthomatosis, amyloidosis, neurodermite, scleroderma, pemphigus, Dühring's disease, ulcus cruris and pruritus. The discussion of skin diseases produced by physical agents is presented also, as a subheading in this section the action of x-rays on healthy and diseased skin is discussed, and the last part deals with skin diseases produced by chemical agents and includes the drug eruptions or toxidermas as well as external irritant or occupational dermatoses.

Under the general heading of conditions of unknown etiology there is first discussed the abnormal conditions of the skin such as the atrophies and dystrophies. Under the latter is grouped pseudo-xanthoma elasticum, livedo racemosa, seborrheas, parapsoriasis, diseases of the hair, diseases of the nails, and erythrodermias. Under chronic granulomas is included a discussion of lupus erythematosus, lymphogranulomatosis, mycosis fungoides, leukemias, granuloma pediculatum, molluscum contagiosum, lichen planus, and kraurosis vulvae. Neoplasms are subdivided into benign new growths of the skin, under which is included nevi, fibroma and keloids, lipomas, myomas, syringocystadenomas, adenoma sebaceum, warts, blue nevi, urticaria pigmentosa and cystic tumors. The second part deals with malignant growths, including a discussion of sarcomas of the skin, melanoma, Bowen's precancerous dermatosis, and skin cancer. Special discussions treat the new advances in the study of allergy, five pages of text is devoted to the discussion of vitamins and four pages to hormones.

One notes a variation in the manner of classification of skin diseases as compared to that seen in the conventional American textbooks on dermatology. An attempt is made to group and discuss skin diseases as reactions of the skin as an organ, locally, to disturbances in the whole body. There are no illustrations to supplement the descriptions in the text. This is a drawback in a book intended for students and physicians who are not experienced in the diagnosis of skin diseases. The discussion of syphilis and the acute exanthemas, usually included in American textbooks of dermatology, is omitted.

The book gives a different point of view in the classification of skin diseases although controversy may exist over the grouping of some of the cutaneous entities as given, it is a work deserving of a place in the library of those interested in this branch of medicine.

**Psycho Analysis for Teachers and Parents. Introductory Lectures** By Anna Freud. Translated by Barbara Low. Cloth. Price \$1.75. Pp. 117. New York: Emerson Books Inc. 1935.

This book contains a series of four lectures delivered by Anna Freud to parents and school teachers in Vienna. It is a simple and authentic presentation of those most fundamental concepts of psychoanalysis which have a specific interest for parents and educators. The aim of the lectures is not only to give the audience an abstract view of the subject but to bring it into relation with the actual problems with which parents and educators have to cope. The four lectures are on (1) infantile amnesia and the Oedipus complex, (2) the infantile instinct life, (3) the latency period and (4) the relation between psychoanalysis and pedagogy.

In the first lecture the author emphasizes that the 6 year old child with whom the teacher has to deal is by no means totally flexible but already constitutes a well defined little personality. The importance of the first five or six years of a child's development is stressed, and the amnesia covering these first years is explained. The child's emotional conflicts in relation to the siblings and parents are vividly and convincingly described as those events which specifically become the objects of the infantile amnesia but which at the same time have a dynamic effect on the child's later behavior and personality development.

The second lecture undertakes the difficult task of giving a popular description of the vast observational material regarding the first manifestations of the child's instinctual life and attempts to explain them as the different phases of an evolutionary process. The pregenital manifestations of sexuality as well as the early manifestations of genital impulses in children, a field that is difficult to discuss without provoking strong emotionally conditioned objections, are convincingly described.

The third lecture, devoted to the latency period, mentions the interesting fact that men of the present civilization have intuitively chosen the right time in which teaching of children can most advantageously start. This is the time around the sixth year in which the first onslaught of the sexual instinct is abated and intellectual curiosity takes the place of the earlier and cruder manifestations of the instinctual life. The author in a brief and immediate fashion describes the formation during this period of the restrictive forces in the child's ego, the absorption by the child of the educational principles imparted to him by the parents in the form of the development of the superego.

In the last lecture the author turns to practical pedagogic problems and describes the two types of maladjustments in children: (1) the group of inhibited children, in which over-severe restrictions lead to the development of an inhibited personality and (2) the neglected youth which does not learn gradually the necessary restrictions of the instinctual life and becomes negativistic and refractory against the educational attempts during the latency period and later. The fact that children between the sixth year and puberty as a rule become less spontaneous and more dull than they were in their earlier years is explained by the author as the price which we have to pay for becoming civilized and domesticated. To minimize this dulling effect of restrictions and repressions is an important task of education which at the same time has to avoid the other danger of giving unrestricted full rein to the manifestations of the child's original instinctual needs which would make him later unsocial.

The author summarizes the benefits of the knowledge of psychoanalysis for teachers. Though psychoanalysis is unable as yet to formulate simple and practical pedagogic rules its knowledge has significance for the teacher because (1) it offers a criticism of existing educational methods, (2) it extends the teacher's knowledge of human beings and his understanding of the complicated relationship between the child and the educator, and (3) as a method of therapeutic treatment analysis of children is able to repair injuries that are inflicted on the child during the process of education.

The author ends her presentation with an instructive example of a teacher, showing how the emotional conflicts of this educator affected her relation to the child entrusted to her. This is the story of a governess who became very successful in influencing the development of a young boy who was retarded and dull and who played a subordinate part in the family in contrast to his two gifted and attractive brothers. Under the influence of her loving attention this boy after a while became the most valued member of the family circle but as soon as this success had been achieved the governess's relation to the boy changed, she had difficulties with him and finally had to give up his education. The explanation was that the governess herself in childhood was a neglected child and thus could identify herself with this neglected boy. As soon as he became successful he became associated in her mind with her successful siblings, and her reaction toward him became destructive. The author emphasizes that educators should know their own emotional weak spots in order to handle correctly the children in their charge.

**New Principles of Anti Rabic Treatment and Rabies Statistics. A Statistical and Experimental Study.** By Maria J. Van Stockum. Volume I. Paper. Price 4.80 guilders. Pp. 204. The Hague: Martinus Nijhoff, 1935.

This volume, by Maria J. Van Stockum of the Pasteur Institute Bandung, Netherlands East Indies, is comprehensive and in two parts. Part I, on comparative rabies statistics, has three chapters on a new method of analysis of rabies statistics: rabies statistics of natives in the Netherlands East Indies 1895-1932 and results obtained in other countries with the Hogyes method with rabbit fixed virus and with some methods with fixed virus killed or attenuated by means other than by drying. Part II is devoted to treatment accidents with chapter 5 on the etiology and diagnosis of treatment accidents and on the prevalence of treatment accidents in those treated with the Pasteur and Hogyes methods.

The interest aroused by the title on the possibility of new principles of antirabic treatment is not sustained for this portion of the title applies to the principles for handling rabies

statistics. The author's treatment of the statistical data is worthy of detailed study. Aside from a realization of their actual worth much valuable information is learned of the author's knowledge of the many-sided rabies problems, which is profoundest in statistics and rather limited on the technical or research phase. No planned controlled experimental testing is mentioned. The author's attitude is rather critical and seemingly unaware of several established procedures, as for example the continued and increasing use of phenolized rabies vaccine. He states that phenolized vaccines can no longer be advocated for immunizing purposes. Furthermore, the statement 'The results of immunization as a rule largely depend on the species supplying the fixed virus in relation to the species to be immunized' is unsupported by experiment and general experience. Rabbit fixed rabies virus readily immunizes man and protection tests are recorded that dogs injected will withstand an infective dose of street virus.

The importance of early rabies vaccine treatment is well stressed, particularly for those victims in whom the period of incubation may be within thirty days but the author seems still to be of the opinion that something worth while can be accomplished by adding doses to the treatment particularly in cases with incubation periods of half or less than thirty days. Evidence exists that protection largely depends on the first few doses of the treatment. The use of solution of formaldehyde in the conversion of a toxin to a toxoid is stressed as a reason for replacing a phenolized with a formaldehydized rabies vaccine. No information is given about the prolonged effect of formaldehyde on rabies virus which is undoubtedly made noninfective in twenty-four hours at 37°C. Unless the formaldehyde is removed it will affect the antigenic properties of the vaccine much quicker and more completely than phenol.

The two sets of conclusions are comprehensive and fully reveal the coverage of the volume. Those having to do with treatment accidents are not supported by informative data.

**Teoría de los neoplasmas.** Por S. Santamaría. Paper. Pp. 163 with 13 illustrations. Madrid: J. Pueyo Imp., 1935.

The author proposes a new hypothesis for cancer, believing that it occurs only in species which reproduce themselves by amphimixis and not in those in which reproduction is parthenogenic, thus placing the responsibility on the combination of pre-existing hereditary elements. A large portion of the discussion is based on a survey of the literature, chiefly drawn from paleontology and embryology. One illustration even is a reproduction of the famous buffalo from the walls of the caves of Altamira, presumably done some 30,000 years ago. Just how profitable such theoretical studies may be depends on the possibility of an experimental attack and this does not seem feasible from the author's presentation. A bibliography of thirty-four references is appended.

**Textbook of Nursing Technique.** By Irene V. Kelley, R.N., B.S., Director of Nursing Education, St. Alexis Hospital School of Nursing, Cleveland. Third edition. Cloth. Price \$2.50. Pp. 425 with 79 illustrations. Philadelphia and London: W. B. Saunders Company, 1935.

This is an excellent textbook of nursing technique or procedure. At the end of each section is the usual questionnaire for review and practical exercises. The work is systematically arranged and graded through the different periods of nursing training and study, the presentation of the subject matter is simple, complete and practical, numerous charts, tables and illustrations accompany the text. This work should prove valuable for all engaged in the study of nursing. Most physicians could read it with profit.

**L'année thérapeutique. Médications et procédés nouveaux.** Par A. Ravina. Neuvième année 1934. Paper. Price 18 francs. 1 p. 191. Paris: Masson & Co., 1935.

This is the ninth annual review of newer therapeutic procedures published in this series. Ravina endeavors to cover in this little volume the therapeutic progress that has occurred during the year not only in France but also in other countries. The topics are classified under three headings: (1) the treatment of diseases and symptoms; (2) new techniques and apparatus; (3) new remedies. As some of our annual reviews published in the English language may be somewhat deficient in adequate presentation of progress as reported in French medical literature this annual is always welcome.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Workmen's Compensation Acts Appendicitis Aggravated by Trauma**—An automobile driven by the deceased employee struck an elevation at a street intersection and skidded into a ditch, jarring and jolting the deceased. At the time of the accident, the deceased made no complaint of injury but about thirty minutes later, according to the testimony, he did complain that he had hurt his abdomen. Two days later an abdominal pain in the region of his stomach developed and on the sixth day after the accident an appendectomy was performed and a ruptured gangrenous appendix removed. Peritonitis and intestinal obstruction developed, resulting in the death of the employee three days later. The claimant instituted proceedings under the workmen's compensation act. The compensation commissioner disallowed compensation and, from a judgment by the trial court upholding the commissioner, the claimant appealed to the Supreme Court of Nebraska.

Prior to the accident, the deceased employee had had attacks of appendicitis. The claimant contended that the deceased sustained abdominal injuries when he was thrown against the steering wheel and that a preexisting chronic appendicitis was thereby aggravated. There was evidence that the preexisting abdominal condition might and probably would have been lighted up by the striking of the deceased's abdomen against the steering wheel. But, said the Supreme Court, there was no evidence that the deceased was thrown against the steering wheel at the time of the accident or otherwise sustained any injury to his abdomen. The complaint alleged to have been made by the deceased, thirty minutes after the accident, that he had hurt his abdomen, was clearly, in the opinion of the court, a narrative of a past transaction or event and was inadmissible in evidence. It was not a spontaneous or involuntary statement made during the happening of the event in proof of which it was offered as evidence. The declaration was, in other words, not a part of the *res gestae*. The most that the evidence showed, therefore, was the possibility or probability that the alleged injury could have happened at the time and place alleged. Awards of compensation cannot be based on possibility, probability, speculation or conjecture. The Supreme Court therefore affirmed the judgment of the trial court denying compensation—*Milton v City of Gordon (Neb)*, 263 N W 208.

**Malpractice Insurance Failure to Notify Insurance Company of Claim Filed Thirteen Years After Treatment**—The Aetna Life Insurance Company issued to Dr Willis Walley, June 20, 1919, an insurance policy, to continue in force for one year, whereby it agreed to indemnify him against loss arising out of any claim based on malpractice. By the policy the physician was required to give immediate notice to the company of any claim made against him for damages. In January 1920 the physician operated on a patient and thirteen years later, in March 1933, he received notice from the patient's attorney making claim for damages based on the alleged failure to remove a drainage tube inserted during the course of the operation in 1920. The physician denied liability and suit was filed Nov 28 1933. The physician had not kept his insurance policy and did not remember by what insurance company it had been issued. He made no effort to ascertain the name of the company until after suit was actually filed. He did not learn the name of the company until February 1934 at which time the suit was at trial. The company then agreed to appear and defend the suit, provided the physician would agree that the insurance company should not be held to have waived its right to complain of the physician's delay in notifying it of the claim. The physician declined to do so, and the attorneys for the insurance company refused to defend the suit. Judgment was thereafter given for the patient. In the present suit, the physician sought to recover from the insurance company the amount paid by him under this judgment, and the expense incurred in defending the suit. The trial court gave judgment

for the physician, and the insurance company appealed to the Supreme Court of Mississippi, division A.

The notice requirements in the insurance policy, said the court, conferred a valuable right on the company, the purpose of which was to enable it to investigate a claim against the insured covered by the policy, to decide whether the claim should be settled without litigation, and, if not, to prepare its defense. No such timely notice was given in the present case. The physician contended, however, that it was impossible for him to have given the notice earlier and that therefore he was excused from so doing. The impossibility, observed the court, did not arise because of the nature of the act to be performed, but wholly because of the inability of the physician himself to perform it. The failure of the physician to keep his policy occurred through his own fault. His delay, from March, when he first received notice of the claim, to December, shortly after suit was filed, to make any attempt to ascertain the name of the insurer constituted, in the opinion of the court, negligence. The Supreme Court, therefore, reversed the judgment of the trial court and gave judgment for the insurance company—*Aetna Life Ins Co v Walley (Miss)*, 164 So 16.

## Current Medical Literature

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Outpatient Obstetrics.**—Buxbaum reports on 6863 cases in which 6537 deliveries occurred in poorly furnished insanitary homes during a period of two years. The operative incidence was about 4 per cent of which 74 per cent were forceps deliveries. There were forty-five cesarean sections an incidence of 0.65 per cent. The fetal mortality was 1.6 per cent 104 deaths. The fetal mortality for forceps deliveries was 5.2 per cent, versions 34.6 per cent prolapsed cord 29 per cent rupture of the uterus 100 per cent breech presentation 7.7 per cent and cesarean section 20 per cent. Twelve mothers died three in their own homes a maternal mortality of 0.17 per cent. The author states that conservative patient management of obstetric cases, especially when delivered in the home is undoubtedly the prime factor in keeping down in already unnecessarily high fetal and maternal mortality. While it is desirable to get a live healthy child one is never justified in doing this at any moderate risk to the mother.

**Vascular Aspect of Eclampsia.**—Irving arrives at the following conclusions from a study of the pathology in pre-eclampsia and eclampsia. 1 There is considerable evidence that the disease is vascular in nature and may best be explained on the basis of arteriolar spasm. 2 Hypertension is probably a protective mechanism. Any measures directed solely toward a reduction of blood pressure are productive of little benefit. 3 Edema may cause considerable harm and active steps should

be taken to bring about its removal. Free watery catharsis, produced by large oral doses of magnesium sulfate, is an effective method of reducing anasarca. Diuretics acting directly on the glomerular endothelium and epithelium are contraindicated, since owing to the nature of the lesion of the kidney they cannot be employed on a rational basis. The intravenous use of concentrated dextrose solution is sometimes useful in stimulating the secretion of the kidney when recovery is under way, but it is often of little benefit in the presence of complete, or almost complete, urinary suppression. 4 The best treatment for eclampsia is prophylaxis. For this reason each case of preeclampsia should be carefully studied from the aspect of abnormal physiology and delivery effected when improvement under treatment fails to take place.

**Effect of Excessive Cigaret Smoking on Maternal Health.**—Campbell submitted a number of questionnaires asking whether the smoking and inhalation of twenty-five or more cigarettes daily have an unfavorable effect on maternal health. An analysis of the seventy-five replies received indicates that a cross-section opinion held by leading obstetricians of this country is unfavorable to smoking among expectant mothers, except in moderation. The author believes also that in many cases there is a strong susceptibility to nicotine, and that complete abstinence is in many cases highly desirable and even necessary as one of the safeguards to maternal health. He has observed women who are not excessive smokers in whom the nervous digestive, respiratory and circulatory systems have been noticeably affected. He believes that the indulgence of so many American women in the use of barbiturates and other sedatives for insomnia is frequently associated with excessive smoking. So far as the clinical symptoms are concerned which arise from excessive smoking or from susceptibility to nicotine, nearly all the important functions of the body are to some extent disturbed by it and physicians should endeavor to evaluate properly its influence and specifically advise each patient who insists on smoking according to her sensitivity to it. Absorption of nicotine in some way produces definite histologic changes in the ovaries of rats, mice and guinea-pigs which results in some instances in sterility and unhealthy offspring. The unfavorable effects of excessive cigarette smoking on maternal health are not sufficiently recognized and are of enough importance to demand a closer observation of clinical manifestations and a continuation of experimental work.

**Hydremia as Factor in Anemia of Pregnancy.**—According to Feldman and his associates determinations on the blood of normal pregnant women revealed an increase in water con-

tent with a concomitant fall in hemoglobin, cell volume and refractive index. As these data are similar to those previously obtained with the pregnant rat it was considered possible that the hydremic condition might be general in the pregnant state. The dairy cow however proved to be an exception. Apparently in this species physiologic adjustments to changes in fluid secretion as well as to pregnancy are more easily made.

**Effect of Atropine and Pilocarpine on Emptying Time of Stomach**—Herrin studied the effect of atropine and pilocarpine on the gastric emptying time in thirteen healthy persons. With one exception these were first and second year medical students. He observed that atropine increases both initial emptying and final emptying times of the normal human stomach. The lengthening of final emptying time is due to two delays in evacuation. One occurs during the first half hour after the meal and the other occurs near the end when the volume of gastric contents has become greatly reduced. These observations are interpreted as a demonstration of the importance of the vagus nerve in maintaining the gastric tonus and peristalsis necessary for a normal emptying of the human stomach. Pilocarpine in most of the subjects favored initial emptying. However, in ten of the thirteen subjects final emptying time was increased from a slight to a moderate degree. For about two thirds of the emptying, the rate with pilocarpine is as rapid as the normal or faster. The delay in evacuation comes only near the end. The favorable effect of pilocarpine on gastric evacuation demonstrates the value of strong gastric tonus and peristalsis in the mechanism of emptying and how these two factors can be heightened by vagal activity. The delay in the completion of evacuation may well be considered evidence of Thomas's enterogastric reflex. Atropine increased the initial emptying time in six of the eight subjects taking farina from 60 to 436 per cent and in three of the five subjects taking a gelatin meal from 57 to 222 per cent. The final emptying time was increased from 40 to 154 per cent in the eight subjects ingesting farina and from 4 to 95 per cent in the five subjects taking the gelatin meal before the injection of atropine. Pilocarpine decreased the initial emptying time in five of the eight subjects taking farina from 11 to 70 per cent had no effect in one and markedly increased it in another. It shortened the initial emptying from 16 to 25 per cent in two of the five subjects taking gelatin. Pilocarpine increased the final emptying time in ten of the thirteen subjects from 5 to 71 per cent and shortened it immaterially in the others.

**Rapid Slide Test for Serologic Diagnosis of Typhoid and Paratyphoid**—Welch and Mickle discuss a rapid slide test for the diagnosis of typhoid and paratyphoid. Concentrated antigens with undiluted serums are used. The test follows in general the Huddleson technic for the diagnosis of Brucella infection, the efficiency and accuracy of which have been demonstrated. The slide test for the diagnosis of typhoid and paratyphoid makes use of four antigens: an alcohol treated Eberthella typhosa O, Eberthella typhosa H, Salmonella paratyphi and Salmonella Schottmuelleri. The antigens are about the consistency of thin cream and are prepared by growing large

quantities of organisms on agar in Blake bottles and washing the growth off with concentrated saline solution with formaldehyde. All antigens are standardized by titration against known positive and negative serums, the titers of which have been previously determined by a standard tube test technic. The test takes approximately four minutes to complete. The rapidity and ease with which it may be carried out in a routine manner seemed to the authors to be an important factor in public health laboratories when speed and accuracy in reporting results to physicians are necessary. In hospitals when an early exclusion of typhoid in certain undiagnosed cases is often important the rapid slide test should be invaluable. The results obtained in a study of 1,100 serums indicate that the slide test is at least as sensitive and specific as the tube tests with which it was compared.

**Extension of Gastric Carcinoma into Duodenum**—Castleman states that from 1900 to 1931 at the Massachusetts General Hospital there were sixty-five necropsies in cases of carcinoma involving the pylorus. In many of these cases sections from the tumor alone, without duodenum were preserved. In six of these cases the growth had invaded the duodenum. During the years 1919 to 1934 inclusive the laboratory received 134 surgical specimens of stomach resected for pyloric carcinoma. In some specimens sections of the duodenum were not preserved but making no allowance for these fifteen specimens showed duodenal extension. In 1934, when special attention was given to this subject there were seven out of twenty-eight surgical cases that showed duodenal extension. This high percentage emphasizes the necessity for the pathologist to take sections of the duodenum in all cases of prepyloric carcinoma. The six cases from the necropsy group and the fifteen from the surgical group all showed microscopically definite carcinoma for varying distances beneath Brunner's glands. The extension rarely involved the mucosa but spread along the submucosa often in lymph nodes. The extent of the duodenal invasion was measured in millimeters from the microscopic slide and because of the marked shrinkage in the tissues due to fixation and dehydration the figures were corrected to correspond to the gross specimens. This degree of shrinkage for tissues fixed in Zenker fluid dehydrated in the alcohols and xylene and embedded in petrolatum was found to be approximately 20 per cent. Nine of sixteen pylorotomies showed tumor cells at the extreme edge of the resection, apparently indicating that carcinoma was still present in the remaining duodenum in only six was normal duodenum present beyond the farthest deposit of carcinoma. The sections from the necropsy cases were cut too short, because all six showed tumor at the extreme cut edge. The significance of the statistics is that the surgeon should resect more duodenum. The first portion of the duodenum measures on the average 5 cm

This length should allow the surgeon to resect at least 3 cm beyond the pylorus and still leave enough to fold in in the distal portion. If this procedure were followed there would be fewer specimens showing tumor at the distal cut edge and less recurrence along the line of closure.

**Factors in Mortality of Acute Appendicitis**—Pattison believes that, if the patient is seen relatively early after perforation, the result of operative treatment is satisfactory, as evidenced by the low mortality rate in the group with local peritonitis. Also there are many patients in whom a perforation is suspected clinically but at the time of operation the pathologic condition is uncomplicated. In all probability this is the situation in many cases treated conservatively for a peritonitis in which an abscess never forms. Even in cases in which there is an advanced peritonitis immediate operation is indicated as long as the patient is in good condition thereby eliminating the focus of the infection. The argument is advanced that operation traumatizes the peritoneum before immunity is established, and this is deleterious. Even if this were so, the operation can be done with a minimal degree of trauma by using a McBurney incision and spinal anesthesia and by handling all the tissues with extreme gentleness. For the most part conservative treatment in cases with a spreading peritonitis is relegated to patients who are in any degree of shock or who are moribund on admission. The only other group of patients who should be treated conservatively on admission is the group with appendical abscesses whose symptoms have been present for less than seventy-two hours. In this group the abscesses are not adequately walled off to warrant operative manipulation. The total mortality rate for acute appendicitis in the author's hospital is 52 per cent. The mortality rate has increased approximately 1 per cent in the last ten years, in all probability as a result of an increase in the number of surgeons operating and the more frequent use of a right rectus incision. More than two fifths of all deaths occur in patients in the two extremes of life. An accompanying diabetes mellitus exerts a profound influence on the prognosis in acute appendicitis. The mortality rate for appendical abscesses is 86 per cent. Operation on these patients should be delayed until adequate walling off has been obtained. Single preoperative chills are of no prognostic value.

**Uncomplicated Auricular Fibrillation**—Orgain and his associates studied forty-nine cases of auricular fibrillation and seven cases of auricular flutter in none of which definite evidence of cardiac disease was demonstrated by history, physical examination, roentgen study or electrocardiograms of the patients. The ages of the patients in whom auricular fibrillation was present varied from 21 to 75 years. All save three cases were of the paroxysmal type, few paroxysms occurred in 46 per cent of these. Definite etiologic factors were few. Follow-up studies on 90 per cent revealed one probable death from cardiac disease four years

after the onset of paroxysms of auricular fibrillation, six patients with cardiovascular complications which had appeared some years after the first auricular fibrillation, and one patient in whom hyperthyroidism had developed. The prognosis for life and for the maintenance of adequate cardiac function is, with rare exceptions, excellent and the outlook for improvement in the number of paroxysms is also good. Reassurance, the avoidance of exciting factors and the use of quinidine sulfate are regarded as the most useful therapeutic measures. The ages of the other seven patients ranged from 27 to 66 years. All attacks were paroxysmal and varied from one to three instances to innumerable attacks in the remainder. The duration of individual paroxysms was from a few minutes to five years, but usually several hours. Electrocardiographic proof of flutter was obtained in each case. The precipitating factor was clearly exertion in three cases, flutter followed a therapeutic malarial chill in one, and in another it appeared after the removal of a gangrenous appendix with the patient under ether anesthesia. Six patients have been followed up for from two to twenty-seven years after the onset; five are entirely well at the time of writing and the remaining patient at 66, after twenty-seven years, has some dyspnea, cardiac enlargement, apical and aortic systolic murmurs and hypertension, but no signs of congestive failure. The seventh patient was last seen eighteen years after his first attack, when he had frequent paroxysms of auricular fibrillation and roentgen study showed slight enlargement of the left ventricle. Quinidine or its isomer quinine was used alone in five cases, being effective in restoring normal rhythm or preventing paroxysms in three and later proving ineffective in one of these. Digitalis restored normal rhythm in one of five cases in which it was tried. Quinidine after digitalization converted the rhythm to normal in two instances.

**Temperature of Skin Following Ingestion of Food**—Booth and Strang observed the blood pressure and the temperature of the skin after a meal designed to attain satiety on nineteen persons of normal weight and fourteen obese subjects. The response of the blood pressure was identical in the two groups and probably due solely to the work of eating. In the group of normal weight there was an elevation of the temperature of the skin, which began shortly after the start of the meal and reached a maximum of 2 C (3.6 F) in sixty minutes. The elevation of the skin temperature in the obese group was definitely diminished and delayed as compared with that of the group of normal weight. The difference in reaction may be one factor in the delayed sensation of satiety in obese persons and therefore a controlling factor in the determination of the large intake of obese persons.

**Hereditary Factor in Obesity**—Gurney studied seventy-five stout women in the outpatient department of the Buffalo General Hospital with three points in mind: (1) the factors associated with the onset of obesity as compared with the same factors occurring in a not stout control group, (2) the incidence of obesity in the parents of the stout group as opposed to that in the parents of the not stout control group, (3) the body build of the progeny of different matings with especial reference to mendelian inheritance of build. Fifty-five women who were definitely not stout were chosen at random as controls. The control patients came from approximately the same age group and had approximately the same incidence of operations and pregnancies—the two most common factors apparently associated with the onset of obesity. Sixty-three women in the stout group gave a reliable history as to the onset of obesity. Of the forty-one of these who bore children, twenty-nine reported a direct association between pregnancy and the onset of obesity. Of the twenty-four who had major operations, seven reported a direct association between the operation and the onset of obesity. Of the remaining twenty-seven patients, four associated the onset of obesity with puberty and two with the menopause, eight maintained that they were 'always stout' and thirteen apparently had no determinable factor associated with the onset of obesity. When the build of the parents of the stout and the control group is investigated a difference in the incidence of obesity is apparent. Of the sixty-one stout women whose family history seemed unquestionably reliable, twenty-six had a stout mother, nine had a stout father and fifteen had both a stout mother and a stout father. In contrast to this, of the forty-seven not stout patients with an equally reliable family

history, fourteen had a stout mother, one had a stout father and three had both a stout mother and a stout father. This makes a total of 38 per cent, with either one or both parents stout as opposed to 82 per cent in the stout group. If build is inherited, this inheritance must be along mendelian lines. A study of the progeny of different matings in this group shows a definite difference in variability. There were eighty-nine offspring from matings of stout persons, sixty-five of whom were stout. Of the 170 offspring of matings of a stout and a not stout person, seventy were stout. Of the 176 offspring of matings of persons who were not stout, only sixteen were stout. Thus there is present a marked difference in variability in the progeny of different matings. The fact that the offspring of stout parents are more variable than those of parents who are not stout suggests, as pointed out by Davenport, that stout persons carry gametes for slenderness, whereas persons who are not stout rarely carry gametes for stoutness. As a corollary to this, regression to a more normal build as a result of these gametes for slenderness can be seen in the offspring of stout parents to a considerably greater degree than in the offspring of slender parents. There appears to be no definite dominance in the series, which is not essential in mendelian inheritance.

**Epidemiology of Meningococcal Meningitis.**—Rake states that an examination of our knowledge of the epidemiology of meningococcal meningitis and of the relationship of the organism to the human host during the initial stages of infection becomes of the greatest importance. His discussion of some aspects of this knowledge reveals many "blind spots" in which comprehension is still very vague. 1 While some evidence has been obtained on the differentiation of parasitic and saprophytic strains it is as yet much too scanty to form a sound basis of any definite generalization. 2 Certain accepted facts regarding the duration of the carrier state are open to question and this question will have to be investigated anew. 3 Through the introduction of a new technique it has been possible to carry out some investigation of the heretofore unknown comparative virulence of case and carrier strains. The results obtained are scanty but are sufficiently suggestive to warrant further work along these lines. 4 The precise relationship of the organism and the host during the carrier state is still unknown, though there is evidence that in certain cases it must be intimate and that it may be in the nature of an infection.

**Relation Between Rheumatic Fever and Rheumatoid Arthritis.**—Dawson and Tyson state that the current tendency in American and English clinical medicine to regard rheumatic fever and rheumatoid arthritis as separate and distinct diseases does not meet with universal favor. The authors offer evidence in support of the hypothesis that the two diseases are intimately related and possibly different manifestations of the same fundamental pathologic process. They consider the following phases of the problem: familial relationship, geographic distribution, initiating factors, seasonal incidence, age incidence and clinical manifestations in different age periods, pathologic similarities and immunologic observations. The relationship between rheumatic fever and rheumatoid arthritis is at the present time of greater theoretical than practical importance. For clinical purposes it is important that the two should be differentiated whenever possible, for in typical cases each presents its own symptoms, each demands its own therapeutic management and each requires its own prognosis. For theoretical reasons, a clearer understanding of the nature of the relationship of the two diseases is of great importance and may contribute much to the knowledge of both conditions. The clinical evidence presented suggests that rheumatic fever and rheumatoid arthritis form a continuous sequence of one disease process with different expressions in each individual phase. These different expressions appear to be in large measure determined by the age of the patient, but undoubtedly other factors, such as individual host susceptibility, are also of importance. The pathologic evidence representing a difference in degree rather than in kind, strongly suggests that the two represent different responses to the same, or closely related, etiologic agents. A final understanding of the relationship between rheumatic fever and rheumatoid arthritis will not be possible until the etiology of both diseases has been definitely established. At present there is a certain amount of evidence suggesting that infection by *Streptococcus haemolyticus* plays a part in the production of both diseases. However this evidence is as yet far from complete and even if it could be established that the two diseases are due to the same agent, it would not prove their identity.

**Influence of Tonsils on Rheumatic Infection.**—To estimate the incidence of rheumatic infection in children whose tonsils have been removed and in those whose tonsils have not been removed, Kaiser had the parents of 48,000 children inter-

viewed. Of this number, 20,000 children had been tonsillectomized and 28,000 had not had their tonsils removed. Based on data obtained from the parents, nearly all the rheumatic manifestations occurred less commonly among tonsillectomized children. Rheumatic fever, which is usually a severe type of rheumatic infection, was reported with considerably less frequency in the tonsillectomized children. Among the tonsillectomized children there were 37 per cent fewer cases of rheumatic fever. Muscular rheumatism, termed growing pains was reported only slightly less often in tonsillectomized children. Chorea was noted with equal frequency in the two groups while rheumatic carditis was somewhat less common among the tonsillectomized children. The statistical information based on the parents' history of the child leaves some uncertainty in the value of the data. It does, however, clearly indicate that rheumatic disease occurs in children whose tonsils have been removed, and it also seems highly probable that initial attacks of rheumatic infection are somewhat less likely to develop in children whose tonsils have been removed. Recurrent attacks of rheumatism occurred as frequently in tonsillectomized children as in the untreated ones at all ages except between the ages of 10 and 15, when recurrent attacks are less common in both groups. Though the number of recurrences of such manifestations as rheumatic fever, chorea and muscular pains was not lessened by removal of the tonsils, it was demonstrated that carditis associated with recurrent attacks of rheumatic fever and chorea was somewhat less severe in the tonsillectomized children. Though the removal of the tonsils fails to decrease the number of recurrences of rheumatic infections there is a decidedly lower mortality rate among these children. If other studies show similar results, there is a definite indication in every rheumatic child for the removal of the tonsils.

**Mechanism of Allergic Response**—Vaughan explains the allergic response as an integrated reaction complex, fundamentally protective in nature but defective in execution, since it lacks coordination and a directing influence. It is in essence a manifestation of environmental maladjustment. Given sufficient heavy exposure (contact, meteorological, food infections), 100 per cent of the population is capable of responding abnormally, either with hyperergy or allergy. There appear to be all grades from those who are extremely susceptible to those who are extremely insusceptible. Heredity and the nature of the exciting factor appear to play a part in determining susceptibility. Heredity represents either a congenital inability to adjust or a congenital predisposition to maladjust. Such a person is often spoken of as vagotonic. The mildly allergic individual may become sensitive to a relatively new or strange allergen with which he comes into only occasional contact. The person with high susceptibility may become sensitive to these and also to those substances with which he comes in frequent or constant contact. If susceptibility to the development of allergy varies from 0 to 100 per cent, one would expect occasionally to find persons who are allergic to practically everything. Such types, although fortunately uncommon undoubtedly do exist. Until now chief effort has been given to neutralization or counteraction of a specific response to recognized specific allergens. It seems possible that efforts to develop a nonspecific or physiologic means of controlling the perverted disoriented reaction of protection so that it may become a normal oriented reaction might actually lead to the discovery of a remedy that will adequately control the response irrespective of the activating cause.

**Hematologic Reactions Following Arsphenamines**—In summarizing the toxic manifestations of arsphenamine on the blood Rich finds that it may act in two ways. 1. It is capable of destroying some of the circulating elements, the platelets and

the white cells in particular. This type of reaction comes on immediately or shortly after the injection and is not serious. Recovery occurs within a few days. 2. It may cause an aplasia of one or all of the hematopoietic tissues in the marrow, depending on the degree of poisoning. In the less serious cases only the platelets or the granular cells are involved while in severe cases all the marrow elements are affected. This reaction is more delayed than in the peripheral type and has a high mortality. Recovery, if it does occur is slow. These reactions are frequently preceded by minor toxic manifestations. Symptoms of purpura, pallor, weakness or sore throat should be regarded as such, and further treatment should be withheld until the blood is examined. A white count alone will be sufficient in most cases, if it is 4,000 or more it is probable that the marrow has not been affected. Only in this manner will one be able to forestall the more serious reactions. Little can be said with regard to the treatment of the blood dyscrasias once they have occurred. The peripheral type needs no treatment other than symptomatic relief. When there is actual depression of the marrow the problem is different. The patient must be tided over with a minimal risk of infection until the marrow regains its ability to produce cells. Transfusions of whole blood accomplish this best. They should be given at frequent intervals to maintain the count as high as possible. Of equal importance with the blood transfusions is proper oral hygiene to prevent, if possible the stomatitis and angina. The diet should be nourishing and rich in vitamins. Iron and liver are frequently prescribed. If recovery should occur, it must be emphasized that further treatment with arsphenamines must never be given.

**Salmonella Suispestifer Infection with Surgical Complications**—Walker and his associates report two cases with localized surgical lesions due to the American type of *Salmonella suispestifer*. In the first case following a transient bacteremia a metastatic splenic abscess developed, causing the clinical picture of left subdiaphragmatic abscess. Surgical drainage of the abscess relieved the patient. In the second patient *Salmonella suispestifer* was responsible for cholecystitis with the usual clinical course. In spite of the fact that both patients were adults *suispestifer* infections in man have been reported most commonly in babies and children. Unless serologic and bacteriologic studies are complete many of the lesions associated with *Salmonella suispestifer* will be attributed to some unidentified gram-negative motile organism. Localized surgical lesions associated with *Salmonella suispestifer* are

rather rare and they are similar to the surgical complications of typhoid and paratyphoid. Suppurative abscesses, in the majority of instances, occur probably as the result of septicaemia secondary to a gastro-intestinal infection due to contamination of food with *Salmonella* *supestifer*.

**Liver Deaths in Surgery**—Boyce and McFetridge analyze twenty-three deaths following biliary surgery, five following pancreatic surgery and six following liver trauma, all of which are indubitable instances of the so-called liver-kidney syndrome. A brief report is also made of the same syndrome in burns, intestinal obstruction and thyroid disease. From their experimental work they feel justified in drawing the following conclusions: 1 The renal changes found at necropsy are the end result of the release of the biliary obstruction and not of the obstruction itself, since they were absent in the dogs that were killed for necropsy before their experimental obstruction was released. 2 Hepatic changes are a constant concomitant of any cholestatic disease, but the extreme changes seen in this type of case are not so much the result of the original obstruction as of its release. 3 Whatever may be the nature of the toxic substance present in the liver in such cases, it is water soluble, since the typical picture could be reproduced only by aqueous and saline extracts made from the liver of the patient who died a "liver-kidney" death after cholecystectomy and not by the alcoholic extract. The authors feel almost certain that they could have reproduced the same picture with extracts made from the livers of the dogs which died a *uremic* death after release of their experimental biliary obstruction had they used them in stronger concentration. They are conducting a series of experiments to determine this point. Their combined experimental and clinical observations have led them to evolve the following explanation of the liver-kidney syndrome. The patient with biliary disease exhibits some degree of liver damage, which is not incompatible with the stress and strain of ordinary life. But when surgery is undertaken, even under the most favorable circumstances, other factors are introduced, and with these new factors the liver, already the seat of a pathologic process, cannot cope. As a result its function promptly fails, and the toxic substances that reach it in the course of normal body metabolism are thrown off undetoxified. The kidney, which is, after the liver, the great detoxifying organ of the body must take up the work of the liver purely as a physiologic matter when the detoxifying function of the

liver fails. But in the kidney the margin of safety is very slight, it promptly breaks down in its turn and an overwhelming and lethal toxemia is the natural consequence. The hepatic changes in these cases always precede the kidney changes, and, if the patients who die promptly with hyperpyrexia and who exhibit liver degeneration at necropsy could be kept alive long enough, they would show precisely the same clinical and post-mortem renal changes as do the patients who die later with typical symptoms of uremia.

**Biologic Effects of X-Radiation**—Clark believes that the undoubted value of x-rays as a research tool to the biologist in the field of genetics has been convincingly demonstrated in the last few years by the work of Muller of Texas and a number of other workers. Much less well known are the great possibilities of cell studies depending on an increasingly quantitative evaluation of characteristic radiosensitiveness, which may well become the most powerful method of pathologic diagnosis. Uncertainty remains as to fundamental differences between normal and pathologic tissues, and the mechanism involved in radiobiology and therapy of cancer cells. It has seemed desirable to the author, therefore, to summarize briefly the present knowledge of the biologic effects of x-radiation, under the following heads: bactericidal and general lethal effects, biologic dosimeters, effects on the hereditary material, effects on normal cells, the radiosensitiveness of cells, recovery and the time factor, x-ray effects on human tissues, the stimulating effect of x-rays, photochemical experiments with a possible bearing on biologic effects, medical implications of cell radiosensitivity.

and reactions to radiation, with especial reference to cancer and a new x-ray method (x-ray diffraction method of structure analysis) of pathologic diagnosis

**Diverticulum of Cardiac End of Stomach**—Nathanson and Steiner report a case of diverticulum of the stomach occurring in a male and found together with a duodenal ulcer. Relatively few of the patient's symptoms were characteristic of duodenal ulcer but could be attributed to the diverticulum. Chronic constipation with severe straining at stool for many years undoubtedly produced increased intra-abdominal pressure and was probably a contributing cause.

**Urinary Frequency in Women**—Wear points out that the three regions that are most likely to be the seat of trouble in extra urinary tract frequency are the central nervous system, the pelvis and the perineum, therefore a rather strict routine procedure should be adopted in efforts at diagnosis. Particular attention should be paid to (1) the duration of the frequency (many of the nonspecific infections of the urinary tract are self limited, and the longer the symptom has persisted the more serious the factors likely to be present), (2) whether the frequency is constant or intermittent and if anything seems to influence it, (3) whether it is worse in the daytime or at night, and if at night whether it awakens the patient from sleep. Many times patients will complain of frequency, yet they will never have to get up at night. In the physical examination the central nervous system should be carefully ruled out. A competent pelvic examination must be done including a visual inspection of the cervix and urethra. An examination of the abdomen will reveal enlargement in the kidney regions and a distended or tender bladder. Then special and laboratory examinations should be performed. Much valuable information may be had from a catheterized urine and an uncatheterized urine that contains pus is valueless in the female. A visual and instrumental investigation of the urethra will establish the presence of urethral stricture, caruncle or urethritis. The plain flat plate will rule out in most cases the presence of renal, ureteral or vesical calculi, as well as the possible presence of a spina bifida occulta. A roentgenogram of the bladder filled with some radiopaque solution will aid in the diagnosis of diverticula and malignant growths. The records of 100 women examined by the urologic department for urinary frequency were investigated. Eighteen different diagnoses were made. The most common condition found was that of low grade chronic pyelonephritis of one or both sides. In sixty one cases the primary involvement was found to lie above the bladder. In seventeen the trouble was found to lie below the bladder. In eight the bladder was the primary seat of involvement and in eleven cases the pathologic changes were found outside the urinary tract. In three cases no cause for the frequency could be found. The bladder showed no visual evidence of pathologic change in thirty-eight cases. This establishes the fact that urinary frequency does not always indicate that the bladder is the primary seat of the pathologic change.

**Prostatic Resection**—Mutland performed diathermic resection by the suprapubic route in ten cases with apparently completely satisfactory results. It has been his experience that about 40 per cent of patients with prostatic obstruction are not fit to stand the shock, sepsis and loss of blood entailed in the performance of a complete prostatectomy at the time when they first come to a surgeon for advice. He has found that the use of the diathermic method of partial resection allows about half of these otherwise inoperable cases to receive the benefit of surgical relief without subjecting the patient to any unduly high risk. The greatly diminished shock, the lessened postoperative pain, the almost complete bloodlessness of this operation and the small area of damaged bladder surface are the factors that contribute to the greater safety of diathermic methods in cases presenting high surgical risk. The largest single factor contributing to the low mortality of this type of operation is the lessened element of septic absorption evidenced by the smooth and afebrile convalescence enjoyed by the author's patients.

### Edinburgh Medical Journal

43 61 124 (Feb) 1936

Physiology and the Surgeon W H Ogilvie—p 61

\*Salicylates in Rheumatic Fever R M Murray Lyon—p 84

Fats of Human Blood C P Stewart and E B Hendry—p 99

**Salicylates in Rheumatic Fever**—Murray-Lyon reviews the records of 100 cases showing the classic symptoms of rheumatic fever on admission to the hospital. From the frequency distribution curve it is seen that 86.1 per cent of nonsalicylate cases cease to show symptoms within four weeks and that 77.4 per cent of the relapses under salicylates occur within the same period and further that relapses are rare when the patient is taking at least 120 grains (7.8 Gm) of salicylate a day. It might seem reasonable, therefore, to propose that all patients with rheumatic fever except the most trivial should be kept on at least this dosage for a month after admission to the hospital. In this way the tendency to recurrent fever should be avoided in a considerable proportion of the cases. The initial dose to be aimed at in an adult should be from 200 to 240 grains (13 to 15.6 Gm) daily, and this amount should be kept up until toxic signs develop or until the temperature has been below 99 F for twenty-four hours. Thereafter a reduction to 180 or 150 grains (11.7 or 9.7 Gm) might be allowed for ten days and after that a dose of 120 grains be maintained until the end of the fourth week. It would be well to continue 60 grains (3.9 Gm) daily until the patient is allowed out of bed when from 30 to 45 grains (2 to 3 Gm) of acetylsalicylic acid might be substituted for a time. The investigation has emphasized the limitations of salicylates in the treatment of

rheumatic fever and has shown that there is every justification for continuing the search for a more reliable antirheumatic agent

**Fluorescein in Lepra Reaction**—Roy and Rao treated twelve well marked inmate hospital cases of fairly severe lepra reaction. Nine were given intravenous injections of 10 cc of a 2 per cent solution of Grublers' fluorescein (water soluble) twice a week or, in a few cases, three times in two weeks, depending on the tolerance of the patients and the response obtained, keeping a close watch on the temperature and erythrocyte sedimentation index, which was determined, as a rule, just before administering the next dose of fluorescein. The sedimentation test was done weekly, even after the temperature reached normal. The required quantity of fluorescein solution was prepared fresh each day. The remaining three cases served as controls. One was treated with intravenous injections of antimony and potassium tartrate on alternate days, 4 cc of a 1 per cent solution in physiologic solution of sodium chloride, prepared fresh just before use, being the dose injected. The second was treated with plain physiologic solution of sodium chloride intravenously in 4 cc doses. The third did not receive any special treatment excepting the routine hospital diet and care. The temperature of the nine cases treated tended to return to normal after from two to four injections of fluorescein, thus partially confirming the opinion of Ryrie. The same tendency of the temperature to return to normal was manifested in the control cases. This tendency can be explained by the supervention of the debility factor impairing the reacting power of the individual. To confirm this explanation the authors have compared the erythrocyte sedimentation index curve with that of the temperature curve, which clearly brings out the fact that, though the temperature comes down after two or four injections of fluorescein, the sedimentation index still remains high. A persistent high sedimentation index means prolonged debility. The toxicity of fluorescein is probably instrumental in precipitating the onset of the debility factor in human beings. Fluorescein seems to have no favorable effect on the natural resistance factor and their observations indicate that it brings down the reaction (1) by a probable antipyretic effect and/or (2) by hastening the onset of the debility factor, which, in control cases, as well as in untreated natural lepra-reaction cases, ultimately brings down the reaction. They conclude that it possesses no particular advantage over antimony and potassium tartrate or other routine methods of antireaction treatment. In cases that are particularly susceptible to antimony and potassium tartrate or do not respond to other measures fluorescein may be used.

**Vitamin E and Antiproteolytic Factor in Serum of Aborting Women**—The experiments of Shute show that rats on a diet deficient only in vitamin E content develop a reaction of the blood serum to tryptic ferment similar to that found in

the blood serum of many cases of human spontaneous abortion. This reaction in the blood of rats developed at about the time when breeding tests indicated that the animals had been rendered relatively or absolutely free of the E vitamin. There was one exception to this in six female rats. This property of the blood serum disappeared from it when wheat germ oil was fed to the animal in considerable quantities before it was killed. Rats fed on a normal diet did not show this antiproteolytic power except in one instance that of a young rat raised exclusively, and during the late winter months, on a bread and milk diet. The experiments indicate that litter mates on the same diet free from vitamin E develop E avitaminosis at unequal periods of time after the diet has been begun. Both the breeding and chemical tests demonstrate this fact. Vogt-Moller has noticed this also. There may be a difference of as much as three months in the development of evidences of vitamin E-freeness in animals exactly resembling one another, without any gross variations in the amount of body fat, and fed from the same diet dish. A few cases are presented to illustrate that preparations of vitamin E administered orally to women whose blood serums are resistant to tryptic proteolysis rapidly restore such serums to normal. The return of the blood to normal digestibility usually coincides with the subsidence of clinical signs of impending interruption of pregnancy. The author believes that vitamin E is another of the factors in the body holding estrogenic substance in equilibrium during normal pregnancy. Vitamin E will remove temporarily the antiproteolytic factor present in certain types of blood serum. It should be administered until the antiproteolytic factor has disappeared and then should be continued with such a dosage as will keep the serum normally digestible. In the average case it takes 6 drachms (24 Gm) of a preparation of vitamin E given in a single dose to render the blood serum digestible in twenty-four hours, then 1 drachm (4 Gm) each day will maintain it in the same condition.

**Experimental Production of Pituitary Tumors**—Cramer and Horning subjected mice to the prolonged influence of estrogenic substance administered by painting the skin twice weekly with a 0.01 per cent solution of the substance in chloroform. The material was applied to male and female mice, both normal and castrated. A mixed strain with a low incidence of spontaneous mammary tumors and a specially inbred strain with a high incidence (about 70 per cent) of spontaneous mammary tumors were used. The five male mice of the high cancer strain which had been subjected to the treatment for a sufficiently long period developed mammary cancer, two of them with tumors in both right and left axillae. The first tumor appeared after sixteen weeks, the last after twenty one weeks of painting with the estrogenic substance. One of the tumors had a metastasis in the lung. Another tumor has been transplanted through three generations so far. A sixth tumor was found in a castrated male mouse of this strain which had been painted for nineteen weeks. An apparently paradoxical result is that none of the females of this strain developed a tumor after being painted for more than six months, although tumors appear in from 60 to 70 per cent of untreated females of this strain when they are more than 6 months old. Of the mixed strain, neither the males nor the females have so far developed a tumor. The results confirm the observations of Lacassagne, who first demonstrated the appearance of mam

mary carcinoma in male mice by injections of estrogenic substance. On the basis of their results the authors emphasize the following conclusions as being of general significance: 1 Estrogenic substance is absorbed by the unbroken skin without producing in it any carcinogenic effect. 2 Unlike the other carcinogenic substances so far studied experimentally, the carcinogenic effect of estrogenic compound is restricted to a tissue remote from the site of application of the carcinogenic agent but possessing a specific physiologic sensitiveness to it. Its action resembles that of the other carcinogenic agents in producing first a hyperplasia of the tissue in which the cancer develops subsequently—the precancerous condition—and in the long period of time necessary to induce cancer. 3 The striking difference between the carcinogenic response to the compound of male mice belonging to two different strains demonstrates clearly the importance of the factor “susceptibility,” which in this case is genetic in origin, in the etiology of cancer. The fact that cancer develops in a site in which it never appears spontaneously demonstrates equally clearly the importance of the extrinsic carcinogenic factor, in this case estrogenic compound. 4 The sensitiveness of the male mamma in its carcinogenic response to the material, contrasted with the great insensitiveness of the female mamma in animals of a pure strain in which the female mamma develops cancer spontaneously in a very high percentage, suggests that either the female organism is able to destroy effectively the excess of the compound administered experimentally or that the carcinogenic response of the mammary epithelium depends on an indirect and not on a direct interaction between the substance and the cells.

Observations on Cardiac Dyspnea. K. Maddox—p 122

Role of Royal Australasian College of Surgeons in Postgraduate Education. A. Newton—p 129

**Observations on Cardiac Dyspnea**—Maddox designates dyspnea as proportional to the ratio of ventilation to vital capacity rather than to either function alone. Dyspnea as a physiologic phenomenon is to be judged not by the amount of distress which it causes but by the degree of physical effort which brings it into being. The physiologic analysis would appear to be made up as follows: 1 There exists a primary diminution of vital capacity from pulmonary congestion. Reflex dyspnea at rest may result from this cause alone. 2 On muscular exertion there is an immediate reflex increase in the rate and depth of respiration arising from impulses from the working muscles and later from the great veins close to the heart. After exercise, dyspnea goes earlier in the normal subject because the venous pressure factor does not persist as it does for a time in the cardiac patient. 3 The increased ventilation exceeds the threshold of dyspnea because of the existence of an already reduced vital capacity. Chemical change then plays little part in mild exertion but may do so in severe exertion. Orthopnea is an important prognostic guide. Orthopnea results in a shift of the blood from the abdomen to the chest, causing an increase of output of the right ventricle for a few seconds. It increases pulmonary congestion, decreases vital capacity and stimulates the vagi to produce a raised ventilation. The threshold of dyspnea is crossed and the patient sits up after which reverse phenomena occur. At a later stage of failure even sitting up fails to relieve the distressing and constant tachypnea. Cardiac asthma is a complex problem. At one extreme are patients with advanced failure of the left ventricle with distended and rigid lungs in which the lung blood depots are full to the utmost and in which the balance is readily tipped in the direction of another attack, and at the other extreme are patients with a minor grade of failure but whose irritable nervous system allows of sudden coronary spasm together with a spontaneous extra load on the left ventricle from general vasoconstriction. Cardiac asthma is always serious—forty sufferers out of eighty-seven were dead within twelve months. Primary overbreathing and the onset of sleep seem to be sufficient to initiate Cheyne-Stokes respiration in cardiac disease.

The overventilation performs this by diminution in the carbon dioxide tension of the arterial blood, resulting in apnea. In an age of medicine forever striving for earlier diagnosis the cardiologist is at a disadvantage. Dyspnea the earliest symptom of heart disease, in its milder forms, is tolerated by the patient, who contents himself with the philosophy of increasing years. When the physician is consulted, the cardiac reserve is already low. His is the difficult task of assessing what remains, steering a course between pessimism and overoptimism and detecting or avoiding the addition of the fearful cloak of neurotic anxiety.

**Glycogen Disease**—Ellis and Payne report five cases of glycogen disease. Although no case has actually been diagnosed at birth, there is every indication that the condition is congenital. The condition may occur as an apparently isolated phenomenon or may affect two or more siblings. There is no established case of direct transmission from an affected parent. In the majority of case reports no information is given as to the presence or absence of consanguinity of the parents. Although the total number of cases is still small the incidence of two marriages of first cousins and one marriage of second cousins among the parents of less than twenty-five family groups is significantly higher than that in the general population. This incidence of parental consanguinity at least suggests that the condition may be inherited as a mendelian recessive character. In general the children affected with glycogen disease appear to have a low resistance to infections of all kinds, death in von Gierke's original cases and in several others being due to pneumonia or influenza. In patients in whom the condition persists over a sufficiently long period some degree of retardation of growth and development is frequent. This becomes more obvious as the children grow older and is seldom noticed before the age of 3 or 4 years. The organs in which the greatest accumulations of glycogen occur show a generalized enlargement which may be of extreme degree. The liver is most constantly involved whereas the spleen has never been found to be affected. Enlargement of the kidneys, heart and pylorus has occurred in certain cases. The enlargement of the liver alone appears to give rise to no symptoms except extreme prominence of the abdomen which brings the patients under observation. Patients in whom enlargement of the kidneys has been described do not appear to have suffered from renal symptoms. Several examples of hypertrophy of the heart due to glycogen retention have been reported and here the condition may give rise to cyanosis and symptoms of cardiac failure. Obesity has been noted in several instances and the distribution of fat has suggested that seen in adiposogenital dystrophy. The absence of jaundice and of bile in the urine and the fact that the van den Bergh reaction is normal have been emphasized in the differential diagnosis of the condition and cases of hepatic infantilism reported by Exchaquet have been excluded from studies of glycogen disease on this account. Transient jaundice however corresponding with the clinical picture of an attack of catarrhal jaundice is liable to occur in the course of the disease. Vomiting, hirsuties and pigmentation have been observed in several cases. The authors summarize the biochemical observations in glycogen disease as follows: (1) the habitual presence of acetone bodies in the urine generally in the morning though not necessarily throughout the day; (2) a low fasting blood sugar; (3) a raised blood glycogen; (4) failure of the blood sugar to rise normally (i.e. over 30 mg. in from fifteen to thirty minutes) following the injection of epinephrine; (5) a

delayed fall, or other abnormality of the blood sugar curve, following the dextrose test meal, (6) a rise, in some cases, of the blood sugar in the half hour following ingestion of levulose, and (7) a raised blood cholesterol. These criteria are not to be regarded separately as diagnostic, and in fact several may coexist in other conditions, when all are present in the same patient, however, and are associated with the clinical features, they form a syndrome sufficiently characteristic to justify the diagnosis of glycogen disease. The etiology of the disease cannot be regarded as established, but the existing evidence points to defect of the glycogen-splitting ferment and is at least consistent with anterior pituitary dysfunction.

**Muscular Degeneration in Late Adult Life**—Nevin points out that primary degeneration of the voluntary muscles in late adult life is not a common disease. The most likely cause of such a condition, especially if it is chronic, is progressive muscular dystrophy. In his two cases microscopic examination of affected muscle obtained at biopsy showed pathologic changes differing at least in degree from those characteristic of progressive muscular dystrophy. In these cases, in different parts of the muscle there were found local degeneration and complete breaking down of the muscle fibers, which was strikingly different from the usual changes in the fibers in progressive muscular dystrophy. The usual changes recognized as characteristic of the pathology of this condition are hypertrophy of some fibers with atrophy of others, proliferation of sarcolemmal nuclei, increase of fibrous tissue and fat and, occasionally, small celled infiltration round the small vessels. The degeneration of the fibers is shown only by gradual atrophy and proliferation of sarcolemmal nuclei inside the sarcolemmal sheath. Alterations in transverse or longitudinal striation sometimes occur; swellings may occur on the fiber, and hyaline or granular degeneration may take place. The main changes in the cases described are strikingly different in that the degeneration of the muscle fiber has taken place not by gradual atrophy of the fiber but by an intense degeneration in which the muscle fibers have broken down the sarcolemmal sheaths have disappeared and the debris of the degenerating muscle and proliferated sarcolemmal nuclei have called forth an apparent phagocytic reaction. The present cases also differed in the absence of any hypertrophy of the muscles and the absence of involvement of the facial muscles. The author believes that separation of his two cases seems warranted by the present knowledge of the subject. This is not a final statement, as detailed pathologic study of the cases might show a pathologic correspondence between these cases and other cases of late progressive muscular dystrophy. At any rate it seems clear that in progressive muscular dystrophy further study is required of the method of degeneration of the muscle fibers especially in cases of late onset.

Corneal Transplantation E. A. Seale—p. 41  
Knoppie Spider Bite M. H. Finlayson—p. 43  
Agglutination and Complement Fixation Tests in Diagnosis of Group of Typhoid Fever Case W. Lewin—p. 45

**Spider Bite**—Finlayson calls attention to the fact that specimens of "knoppie-spider" obtained from the Piquetberg, Valmesbury, Graafwater and Caledon areas have been observed to belong to the genus *Latrodectus*. The symptoms following bites by "knoppie-spider" may vary in different individuals but in almost all cases severe cramplike pain is experienced in the chest or abdomen. Frequently abdominal rigidity is observed, and in the majority of cases profuse perspiration is noted and alivation may be marked. The temperature may be subnormal but it rapidly rises to 102° or 103° F. The reflexes are overactive and the patient is often cyanosed. In some cases nausea and vomiting are present in others difficulty in breathing. Death may ensue from heart failure or respiratory failure. The symptoms are neurotoxic in man and animals and in this respect resemble those produced by Cape cobra venom. In the absence of a specific antiserum the treatment must be the same as for snake bite. The treatment of spider bite advocated by Ingram and Musgrave is given. The use of tetanus antitoxin should be considered in all cases.

Biologic Reactions for Diagnosis of Pregnancy G. Serdaris—p. 128

**Hypocalcemia and Loss of Consciousness**—Kayser and Klotz report several observations of sudden loss of consciousness of undetermined origin. They decided to measure the blood calcium in all such cases and finally obtained records in eleven patients. In all the patients studied there was a hypocalcemia of varying degree, with a normal range of between 95 and 105 mg of calcium per liter of serum. The observations on the patients gave a variation of from 78 to 93. Furthermore, a state of extreme emotion and a tendency to breathlessness usually preceded the loss of consciousness. The actual syncope probably has a cardiac origin. The constant accompanying hypocalcemia suggests the treatment with a recalcifying medication, such as calcium chloride, vitamin D, parathyroid extract or ultraviolet radiation. The pathogenesis is uncertain, but it may be that the manifestations of syncope are dependent on a sudden disorder of the vagosympathetic system of humoral origin.

- Oncotic Pressure of Serum G. Carrière, C. Huriez and M. Laperre—p. 225  
\*Treatment of Sydenham's Chorea by Intramuscular Injections of Magnesium Sulfate M. R. Contreras—p. 228  
Uremia F. Coste and A. Grigaut—p. 229

**Treatment of Chorea**—Contreras believes that the best way of introducing magnesium sulfate is intramuscularly. The preparation which he uses in the treatment of chorea is made as follows: A 25 per cent solution of magnesium sulfate in distilled water is divided into 5 and 10 cc ampules and sterilized in the autoclave. The injection is given every other day with 5 cc for the patients aged from 1 to 5 and 10 cc for older children. The injection is made deep into the gluteal region and is followed by a long massage. Since his original communication the author has observed that the rapidity of recovery is not closely related to the quantity of the medicine or the frequency of injection. In the majority of cases of chorea a quieting of the involuntary movements is observed between the second and fifth injections. The psychic disorders, especially irritability, are also improved. After the first five injections the patient gradually returns to a normal state and as a rule recovery is obtained with ten ampules. No complications other than pain at the site of injection have been observed, except for a slight tendency to sleepiness in one case. The mechanism of action is uncertain. The author does not believe that the cure is accomplished only by the hypnotic action of magnesium sulfate. He feels that the method described is the most rapid and certain for the cure of chorea.

- Toxicity of Stagnant Gastric Content After Gastric Resection and Its Relation to Postoperative Hyperazotemia and Hypochloridemia C. Antonucci—p. 427  
Amebic Abscess of Liver Cases S. Marino—p. 434

**Toxicity of Stagnant Gastric Content After Gastric Resection**—Antonucci states that the grave syndrome of hyperazotemia and hypochloridemia which follows gastric resection in gastric or duodenal ulcers and which, without any other complications, may result fatally is due to alterations of the liver and kidney originating in the absorption of stagnant toxic gastric content by the intestine. The gastric content, a mixture of gastric and duodenal secretions, blood and waste material (particles of necrotic gastric and intestinal mucosae), is secreted and accumulates rapidly after resection, regardless of the technique used, and is highly toxic. Intravenous injections of filtrates of the gastric content, from 2 to 8 cc, in rabbits resulted in death of the animals within one minute to forty-eight hours after the injection. In all the animals there was a marked increase of azotemia and a moderate diminution of chloridemia. The paren-

chyma of the liver and the kidney were congested and greatly injured. The author believes that the results of his experiments support his opinion on the etiopathogenic role assumed by stagnation and intestinal absorption of toxic gastric secretions in the development and evolution of the grave humoral syndrome that follows gastric resection. He points out the advisability of performing aspirations of the gastric content six hours after gastric resection and then once or twice more the next day, a practice which he carries out systematically in all his cases with satisfactory results. His advice is based on the experience of more than 300 gastric resections in gastric or duodenal ulcers.

Latent Bilateral Hydronephrosis in Hypertension. C. A. Zerbini and A. J. Ghibaudi —p 951

**Cystic Degeneration of Internal Meniscus of Knee Joint**—Satanowsky says that direct trauma of a meniscus is the necessary condition for the development of meniscal cystic degeneration of the knee joint. It is followed by degeneration of the fibrocartilage and of the connective tissue and then by secondary vascular and synovial alterations around the meniscus. The process of degeneration follows a prolonged silent evolution until the appearance of the tumor. The latter develops for a certain time and then enters a stationary stage. The fact that the external meniscus is more exposed to direct trauma than the internal one is the reason why the former is more frequently the seat of cystic degeneration than the latter. The author's patient, aged 18, suffered at the age of 12 a penetrating wound of the internal aspect of the knee joint which was followed by transient tumefaction and pain. Six years later a painful tumor developed at the same spot; the pain increased by walking and disappeared at rest. With clinical and roentgen diagnosis of mucous cyst of the internal meniscus, a meniscectomy by Tavernier's technic was performed. The lesions of degeneration were found to be superimposed over the traumatized spot and a longitudinal rupture of the meniscus, caused by the wound, proved to be present at examination of the removed meniscus. The patient regained complete extension and flexion of the knee joint fifty days after performance of the operation. The author says that partial excision of the meniscus at the level of the cyst fails to give satisfactory results, because cystic degeneration reappears some time after performance of partial operations.

### Archiv für klinische Chirurgie, Berlin

Nonspecific Protein Reaction After Blood Transfusion. A. Filatov, N. Blinov, and M. Doepf —p 647  
Postoperative Blood Picture in Total Removal of Stomach. Three Cases. S. Tateno —p 681

**Nonspecific Protein Reaction of Blood Transfusion**—According to Filatov and his co-workers the following factors must be taken into account in considering the frequency of nonspecific protein reaction after blood transfusion: the care with which observations are made on patients following blood transfusion; the nature of the disease for which the transfusion is undertaken; and the question whether the transfusion was performed for the first time. Biologic causes such as the ingestion of a meal by the donor before the transfusion; the relationship of titers of scrums and of erythrocytes of the donor and the recipient; the presence of albumin fractions in the blood; or the use of a universal donor do not play an important part

in the causation of the nonspecific protein reaction. Disregarding the subgroups A<sub>1</sub> and A- results in doubling the number of reactions. The reaction, however, need not take place in every instance in which blood from an improper subgroup was infused. On the other hand, technical errors play a much more important part in the causation of the reaction. The incidence of such reactions may be materially reduced by observing the following precautions: (1) careful cleansing of the apparatus for blood transfusion, (2) prevention of any blood clotting, (3) observance of painstaking asepsis, (4) maintaining proper temperature of the blood to be transfused and (5), what is most important, using distilled water free from any impurity for the solution of chemicals. The authors were able to reduce the incidence of reactions in their last group of 200 blood transfusions to 2 per cent by adhering to these precautions.

**Total Resection of the Stomach**—Tateno reports three cases of cancer of the stomach in which total gastrectomy was performed and the esophagus was anastomosed to the jejunum. Liver metastases were the cause of death in the first case 175 days after operation, while the second and the third patients died 182 and 193 days after the operation from general weakness and anemia. The author found colon bacilli in the jejunum in small numbers; however, their pathogenicity and their relation to the anemia remained obscure. Necropsies revealed that generalized chronic intoxication was the cause of death in the three cases. Systematic examination of the blood demonstrated a diminution in the erythrocytes, hemoglobin content, thrombocytes and reticulocytes. The color index rose. There were no alterations in the red cells characteristic of the pernicious anemia. The anemia observed presented a peculiar blood picture, which the author characterizes as agastric hypoplastic hyperchromic anemia.

Excretion and Absorption of Water by Skin. W. Burr —p 550  
Reducing Substances in Gastric Juice. G. Krause —p 555

**Symptomatic Erythrocytosis**—Otto shows that the exact definition of the term erythrocytosis and the quantitative interpretation of the terms polyglobulism, hyperglobulism, and erythrocytosis require a purely numerical differentiation. Erythrocyte values between 5 and 55 million he designates as erythrocytosis; values between 56 and 65 million as hyperglobulism; and those in excess of 65 million as polyglobulism. To define the lower limits of erythrocytosis the author made studies on normal men and women and found that in men the sphere of erythrocytosis begins with values of more than 48 million and in women with values of more than 461 million. He reports his observations on erythrocytosis in 242 patients observed in his clinic in the last eighteen months. According to the assumed cause of the erythrocytosis he differentiates eleven groups of cases. One group includes patients with intoxications from various types of gases (carbon monoxide, hydrogen sulfide) and mild cases of lead poisoning. He thinks that in this group of patients the formation of blood toxins such as methemoglobin, sulfmethemoglobin, and carbon monoxide, methemoglobin results in an irritation of the bone marrow and thus in erythrocytosis. In another group who had disorders accompanied by hemorrhages of the gastro-intestinal tract and of the kidney (gastric and duodenal ulcers, various types of nephritis, nephrolithiasis, cystitis) the erythrocytosis is probably caused by irritating hemorrhages. Small quantities of blood that are lost daily stimulate the bone marrow which responds to this stimulus with an increased formation and flooding out of erythrocytes. In the erythrocytosis in disturbances of the hepatic and biliary system he says that the indirect formation of bilirubin probably constitutes the stimulus for the increased hematopoiesis. The erythrocytosis of diabetic patients is ascribed to the acidotic condition of the metabolism. The erythrocytosis that develops in hyperthyroidism and thyrotoxicosis results from stimulation of the bone marrow by thyroid substances indirectly by way of the sympathetic nervous

system. The author mentions the erythrocytosis that develops in the physiologic fluctuation of the internal secretions (puberty, menstruation, pregnancy and the menopause) as well as in pathologic conditions of the endocrine system. He discusses various possibilities by which abnormalities in the endocrine system may irritate the bone marrow and thus produce erythrocytosis. Other patients in whom erythrocytosis develops are those with a decreased oxygen intake, that is, patients with pulmonary and circulatory disorders. In these patients the increase in the erythrocytes is a compensatory mechanism. In vascular disturbances there frequently appears a relative erythrocytosis in which the bone marrow is not involved but in which a contraction of the vessels, a forcing out of the plasma and also a contraction of the spleen are concerned. It is probable that the erythrocytosis of diseases of the brain and of the spinal cord is the result of a vascular paralysis. However, the erythrocytosis developing in patients with neoplasms is probably the result of an irritation of the bone marrow. Infectious diseases also may irritate the bone marrow and thus elicit an erythrocytosis. The duration of erythrocytosis differs considerably.

**Oxalic Acid Elimination in Nephrolithiasis.**—Herkel and Koch describe a method for the determination of oxalic acid in the urine and present their observations on the oxalic acid elimination in the urine of rabbits after various diets and tolerance tests and also after the intramuscular injection of oxalic acid glycol or glycolic acid. They found that the oxalic acid elimination fluctuates from day to day in normal persons but that the average value is eliminated, even if the diet is free from oxalic acid and is of low caloric value, because oxalic acid originates chiefly in the intermediate metabolism. Low values were found in diabetes and achylia, but the values were increased in hepatic impairment and in glomerular nephritis as was the case also in some cases of nephrolithiasis. It could not be proved that the hydrogen ion concentration exerts an influence. In tolerance tests with diets that were deficient in oxalic acid and had a standard protein content but varied in carbohydrate content it could be proved that in many cases the oxalic acid elimination follows the carbohydrate content of the diet, and so it is assumed that relations exist between oxalic acid and the carbohydrate metabolism. Aminoacetic acid and meat exerted no influence. Oxalic acid tolerance tests, in the form of spinach meals, resulted in an increased elimination of oxalic acid in healthy persons. After citing tests made to determine the effect of calcium, atropine, hydrochloric acid, histamine and posterior pituitary extract on oxalic acid elimination, the authors state that patients with achylia react to spinach tolerance tests little or not at all. In one case of impairment of the hepatic parenchyma the oxalic acid was increased, owing to a disturbance in the oxidation by the liver. In other cases of hepatic cirrhosis the elimination was normal. The authors made spinach tolerance tests also on twenty-one patients with renal calculi, among whom were a number with an unstable sympathetic nervous system. Eight of these patients showed a normal response, but the others reacted abnormally, which indicates that there are disturbances in the oxalic acid elimination of many patients with renal calculi. However, the cause for this disturbance is probably not in the kidney but rather in a disordered relationship between substance metabolism, the sympathetic nervous system and hormones.

Dietetic Regulation in Spas L Roemheld—p 431

**Subaqueous Exercises in Paralyzed Patients.**—Scholtz asserts that movement is the most intense stimulus for the impaired nerve cell and that exercises are important in the treatment of paralytic conditions. Subaqueous exercises make possible movements of the paralyzed extremity that are not possible out of the water. Owing to the buoyancy which nearly cancels the weight of the body, relatively weak impulses result

in movements. The first aim of the subaqueous exercises is to give the paralyzed patient again the feeling for movement and innervation and also to revive the will to movement. Another advantage is that the bath in the tank permits movements in all direction and does away with friction, particularly in lateral movements. Moreover, the bath exerts stimulating as well as quieting influences on the nervous system. In warm baths the quieting influence predominates. The author points out that the subaqueous exercise treatment, although formerly recommended by von Leyden, Goldscheider and others has recently been given a great impetus by the work done at Warm Springs, Ga. He reports his own experiences with the treatment in approximately fifty cases. He gives the treatments in a tank in which there is a massage table as well as a rest bench. First passive movements are made, but the patient is urged to help with his own efforts. Occasionally, subaqueous massage is applied by means of the subaqueous douche. This douche has a temperature of 45 C (113 F) and is under a pressure of 25 atmospheres. The latter measure improves the nutrition of the parietic muscles and also eases the spastic contractions. In the beginning, the exercises should be carefully supervised and care should be taken that all the paralyzed muscle groups are given some exercise. The patients should remain in the tank for from thirty to sixty minutes. The author obtained favorable results with this treatment in cases of multiple sclerosis, in spastic paresis caused by vertebral injuries and in cases of paralysis caused by polyneuritis and poliomyelitis.

**Renal Impairment in Malignant Diphtheria.**—Brugsch and Fülling show that a renal impairment, recognizable by the appearance of hyaline or granulated cylinders, is found in the majority of patients with diphtheria. With increasing severity of the diphtheria erythrocytes, a large number of casts, leukocytes and epithelia appear in the urine. However, the urinary sediment alone is no sure sign of the severity of the disorder, for the course of the disease may be mild in spite of considerable involvement of the kidneys. The authors examined the blood, particularly for its rest nitrogen content, and found that an increase in the rest nitrogen makes the prognosis of malignant diphtheria rather unfavorable, whereas a reduction of a formerly increased value is a favorable indication. They cite two cases which demonstrate, on the one hand, the contradiction between the clinical picture and the rest nitrogen content and, on the other, the prognostic significance of the rest nitrogen curve. The cause of the increase in the rest nitrogen content is not quite clear as yet, nevertheless, the continuous determination of the rest nitrogen is a method that permits prognostic conclusions independent of the sometimes misleading clinical manifestations and of the urinary sediment.

**Urea and the Differentiation of Diphtheria Bacilli.**—Puschel reports that, in an attempt to improve the culture medium for diphtheria bacilli by the addition of urea, it was found that the diphtheria bacilli grew luxuriantly on this medium whereas the growth of the pseudodiphtheria bacilli was greatly inhibited and the plates had a distinct ammonia odor, that is, the pseudodiphtheria bacilli apparently were able to decompose urea. Subsequently a large number of tests showed that the diphtheria strains did not decompose urea, while the pseudodiphtheria bacilli did. The author points out that studies of other investigators have proved that the capacity to decompose urea is due to the presence of urease in the bacteria. It is said that this ferment is more frequent in the bacteria occurring in air water and soil than in the bacteria that play a part in medicine. Examinations of a large number of patho-

genic strains convinced the author that the presence of urease is a rare biologic characteristic. Since the pseudodiphtheria bacilli have this rare quality, she suggests that the so-called pseudodiphtheria bacilli should be excluded from the group of diphtheria-like rods and should be designated *Corynebacterium ureaticum*. She points out that the capacity to decompose urea is of diagnostic significance, since the demonstration of this characteristic in organisms suggestive of diphtheria rods excludes the diagnosis of diphtheria. Moreover, she thinks that this capacity of the pseudodiphtheria bacilli contradicts not only their identity but even their close relationship with diphtheria bacilli. She stresses that mutation between the two should be recognized only if the bacteria bacilli have actually become capable of splitting urea.

\*Influence of Smoking on Threshold of Stimulus for Sense of Pressure A Wenusch and R Scholler—p 356

**Articular Lesions Resulting from Work with Pneumatic Tools**—In workers who use pneumatic tools, Rostock found that the lesions developing are of two types. 1 Because the musculature is tense to absorb the shocks from the pneumatic tools, traction on the muscles and tendons is increased and reactive bone proliferations develop at the sites of insertion. These proliferations are usually visible in the roentgenogram. 2 The continuous jerks press the articular surfaces against one another and this chronic trauma elicits subchondral necroses, which become manifest in typical osteochondritis dissecans and changes in the shape of the articular surfaces. On the elbow, considerable bone proliferations are observable at the site of insertion of the triceps musculature at the olecranon. The head of the radius likewise shows changes but the most typical form of articular lesion is the bone proliferation at the site of insertion of the brachial muscle. The author illustrates this change in two roentgenograms. Then there may be lesions on the articular surfaces, and movable bodies may develop in the joints. Changes may develop in the wrist and shoulder joints, although they are usually not as pronounced as those of the elbow. The author points out that articular changes of this nature, although they are most frequent in miners and others who use pneumatic tools, nevertheless occur also in other persons who do hard physical work, such as quarry workers, engine stokers, drivers of heavy trucks, workers on chill molds, blacksmiths, washerwomen and operators in shoe factories.

**Influence of Smoking on the Pressure Stimulus**—Wenusch and Scholler studied the changes in the threshold values for the pressure stimulus by experiments with hairs and pendulums. They found that the smoking of tobacco more or less heightens the threshold stimulus for the perception of pressure but that this change soon subsides. The increase is largely dependent on the habituation to tobacco, for the heightening of the threshold of the pressure stimulus is much more pronounced in persons not accustomed to smoking than in habitual smokers, in whom there may be no increase at all. The authors point out that the temporary increase in the threshold of the stimulus amounts to a partial exclusion of the person from the environment, and they think that this might explain why smoking is so often done during excitement.

New Method of Treatment of Endocervicitis and Erosions of Cervix by Means of Intracervical Injection of Ammonia Silver Salt Solution L S Kritschewsky and E Werbatz—p 346

**Treatment of Endocervicitis**—Kritschewsky and Werbatz employ ammonia silver salt solutions in the treatment of endocervicitis and in cervical erosions. They use a 1:20,000

solution in boiled water. Following a preliminary vaginal douche with 1 liter of this solution, the vaginal portion of the cervix is brought down and the external os is wiped with sterile gauze. Then a long needle is introduced into the submucous tissue of the cervix and the tissues are infiltrated with 10 cc of the solution. This injection is made in four directions (anterior, posterior and both sides) into the submucous tissue of the cervix and partly into the muscular layer. This procedure resulted in considerable infiltration and edema of the cervix. In the course of the injection, some of the fluid escaped through the eroded surface into the cervical canal, which was thus irrigated, but at least 2 or 3 cc actually entered the submucous tissue and the muscular layer. In the course of the later injections, when the cervix became softer, the injection was considerably less difficult and from 5 to 6 cc of the injection fluid remained in the cervix. The injections were repeated at five day intervals, and the total number varied between two and eight. The authors obtained favorable results with this treatment in sixty-three of sixty-six cases.

\*Question of Mental Inferiority of First Born H Luenburger—p 109

\*Later Fate of Children with Convulsions Eva Bergemann—p 116

**Leontiasis Ossea and Hereditary Syphilis**—Scharff reports the history of a girl, aged 11 in whom a hard swelling had appeared on the right superior maxilla at the age of 6. The swelling was painless but slowly increased in size. The question arose as to the type of the bone disease. Osteitis fibrosa (Recklinghausen), Paget's disease and Albers-Schönberg's marble bone disease could be excluded but the symptomatology was like that of leontiasis ossea. The author restricts the latter term to a disease entity in which the bone disease is limited to the cranium (more especially to the superior maxilla) leaving the other parts of the skeleton free. Other characteristics are the hardness of the bone process the onset during early childhood and the painless course. However, even after the disorder had been diagnosed as leontiasis ossea, there still remained the problem of etiology. In this connection the author points out that endocrine disturbances, erysipelas, infectious diseases, fetal defects and trauma could be excluded but a concurrence with congenital syphilis seemed significant because the literature reports a number of cases of leontiasis ossea in which the Wassermann reaction was positive and also some in which antisyphilitic treatment had a favorable effect. In the reported case, antisyphilitic treatment was instituted, but although it seemed to arrest further progress it did not produce a regression and since the secondary symptoms (difficult nasal breathing) persisted surgical removal was decided on. In view of the lack of another satisfactory explanation the author thinks that in the reported case the leontiasis ossea suggests an etiologic relation with syphilis.

**Question of Mental Inferiority of First-Born**—Luenburger challenges the conclusion reached by Klenk and others regarding the higher incidence of mental defects in first born children (abstracted in THE JOURNAL February 8 p 502). He concedes that to one not trained in statistics it may appear that thirty first-born in a total number of sixty-four mental defectives seems to indicate that mental defects are more frequent in the first born than in the later births. However he shows that if the proper statistical procedure is employed this is not the case in fact the number of first born with mental defects is somewhat smaller than could have been expected for if as was the case in the investigated material the average number of children per family was only 2.5 it is natural that the first-born would make up a comparatively large number. The author adds that his criticism of Klenk's conclusion does not apply to that author's observation regarding physical defects.

**Later Fate of Children with Convulsions**—Bergemann reports the results of catamnestic studies on persons who, in the years from 1912 to 1930, had been under observation in the children's clinic on account of convulsions or of convulsion-like attacks. The total number of cases investigated was 155. The largest group fifty-nine were epileptic cases, other diagnoses were salaam convulsion, pyknolepsy, occasional convulsions (fever convulsions), convulsions of neuropathic origin, convulsions caused by organic brain lesions (birth trauma, hydrocephalus, encephalitis), jactatio capitis and so on. It was found that in epilepsy a definite prognosis is difficult, for neither the cases that took a favorable nor those that took an unfavorable course showed characteristic signs. However, the author classifies the epileptic patients in two groups: (1) those in whom the intelligence became impaired and in whom character changes appeared in the course of time (twenty-seven cases) and (2) those in whom such changes did not appear in spite of the continuous appearance of the attacks (thirty-two cases). The impairment of the intelligence became always manifest in the course of the observation but character changes appeared in some cases from the beginning of the disorder. The well known unfavorable prognosis of salaam convulsions was corroborated by the author. In discussing pyknolepsy, she emphasizes that this term should be restricted to a definite symptomatology, of which she gives an outline. She also points out that this disorder is frequently favorably influenced by endocrine therapy and she suggests that by means of this therapy it might be possible to differentiate this condition from petit mal. The twenty cases of occasional convulsions proved the predisposition of early childhood for convulsions, for the after examinations revealed that all these patients were free from such attacks. In three other cases however, the after-examination disclosed that the 'occasional' attacks were really of an epileptic nature. The majority of the patients in whom the convulsions had been of a neuropathic origin had a neuropathic constitution but the convulsions had a tendency to disappear.

\*Roentgenologic Observations on Effect of Artificial Pneumothorax on Pulmonary Tuberculosis N F Pershina—p 90

**Roentgenologic Observations on Effect of Artificial Pneumothorax on Pulmonary Tuberculosis**—According to Pershina the extent of reparative processes in a collapsed lung is determined by the type and the age of the lesion and by the duration and completeness of the induced pneumothorax. It appears from the roentgenologic studies of the Leningrad Tuberculosis Research Institute that early infiltrating lesions with a tendency to breaking down require not less than four years to heal and bring about a permanent recovery. Patients presenting fibrous caseating lesions required from five to six years of pneumothorax therapy to obtain a permanent roentgenologic and clinical recovery. Interruption of the collapse therapy at an earlier period led to recurrences with cavity formation after three or four years, especially if the patient lived under unhealthy conditions. Recurrences were likewise observed in cases in which the pneumothorax was complicated by the formation of adhesions. Therefore they advise severance of the adhesions even for cases in which the cavities heal and the tubercle bacilli disappear from the sputum. Diminution of the pulmonary area and its aeration observed roentgenologically after a prolonged collapse therapy suggest that considerable anatomic changes take place within the pulmonary parenchyma. The effectiveness of the artificial pneumothorax therapy can be judged from the fact that fibrous caseating lesions may heal under its influence and even become calcified. Such results are only rarely observed in conservative treatment. Displacement of the heart and the mediastinum toward the collapsed lung need not necessarily be due to alterations in the pleura as was formerly believed but

may be the result of cicatrizing alterations that existed in the lung previous to induction of pneumothorax or due to the effect of a prolonged compression of the pulmonary tissue.

Relation of Cholesterol in Organism Under Normal and Pathologic Conditions Review H Dam—p 113

\*Monilethrix Eleven Cases in Six Generations Preliminary Report U Larsen—p 129

Negative Result in Examination for Minerals in Sarcoid of Skin K A Heiberg and C J Jacobson—p 136

**Monilethrix**—According to Larsen, the disorder in the family in question has been known for centuries. Of the eleven patients he has examined three: a girl aged 1½, her father aged 38, and a paternal aunt aged 32, representing the three forms of development of the disturbance: (1) full development at birth, (2) development during the first half year of life and (3) later development (the last named mentioned only three times in the literature). The keratosis which in numerous cases accompanies monilethrix, especially in childhood, is a secondary phenomenon or has perhaps the same etiology as the monilethrix and in time disappears wholly or in part. Monilethrix is seen as a hereditary trophoneurosis probably of central origin.

Influence of Hypertonic Solutions on Circulation Dextrose Osmosis Therapy E Polack and H Harpith—p 141

Biology of Age and Endocrine Glands H Okkels—p 155

\*Xanthomatosis V Madsen—p 161

**Xanthomatosis**—Madsen says that he has found only six cases of xanthomatosis in the Danish medical literature (cases of Niemann-Pick's and Gaucher's disease excepted). One of these and his personal case, in a woman, aged 55, represent xanthomatosis localized in the skin, without jaundice, three cases, xanthomatosis localized in the skin, with jaundice, and two, Hand's disease. The prognosis in his instance seems less unfavorable than in the third group, but there may be xanthomatous processes in the endocardium, and the chronic liver changes which have existed for a considerable time are grave. Cholecystenterostomy would be justifiable if there are in the biliary or cystic duct partially obstructing processes that compromise the flow of the bile, but at present the risk is considered too great. Roentgen therapy has at most only checked a further propagation of the processes. Continuation of the treatment is intended. The breaking down of the tenth dorsal vertebra is ascribed to xanthomatous metastasis.

\*Hypersensitivity to Aminopyrine and Agranulocytosis A B Hansen and C Holten—p 193

**Hypersensitivity to Aminopyrine and Agranulocytosis**—Hansen and Holten report a case of hypersensitivity to aminopyrine with a granulopenic reaction in a woman, aged 25, with a history of two attacks believed to have been agranulocytosis. The patient had been given about 380 Gm of aminopyrine in the course of fourteen months before the hypersensitivity became evident. The authors' attempts to determine whether patients suffering from various endocrine disorders react differently after the administration of small doses of aminopyrine than do patients with other disturbances, or on the whole abnormally, gave negative results.
